Increasing Magnesite Production.—Until 1915 the United States produced only about 10,000 tons of magnesite annually, although it used 300,000 tons. The domestic supply came from California and the imported material came from Austria, Hungary and Greece. In 1916 the production in California jumped to 150,000 tons, but the imports, if the calcined material is computed as crude rock, fell to 93,000 tons. The supply, therefore, fell short of the demand. Manufacturers of open-hearth steel had difficulty in getenough magnesite bricq to line their furnaces, and companies that made magnesite flooring were short of raw material.

In view of this condition and the decrease in imports, domestic production was greatly stimulated. According to estimates by C. G. Yale of the Untied States Geological Survey, the production of magnesite in California in 1917 exceeded that of all former years, being estimated at 215,000 tons. This quantity and the magnesite produced in the recently discovered field in Stevens County, Wash., estimated by R. W. Stone of the United States Geological Survey, at close to 100,000 tons, makes an output of about 315,000 tons in 1917.

Synopsis of Recent Metallurgical and Chemical Literature

Copper

The Separation of Copper During the Concentration of Copper Matte.—If during the concentration of ferruginous copper matte in the reverberatory furnace the copper content rises above 73-74 per cent, then, according to an article published by W. STAHL in *Metall. u. Erz*, 1917, vol. XIV, pp. 201-202, there is an increase in the separation of copper which normally takes place according to the reaction process:

$$Cu_2S + 2Cu_2O \rightleftharpoons 3Cu + SO_2$$

On adding a crude matte with a high ferrous sulphite content to a molten batch of enriched copper matte, there frequently occurs a special separation of copper which, in the further course of the concentration process, again disappears and is in no way connected with the above reaction. Again on smelting crude copper matte high in iron in the blast furnace there is frequently a separation of iron which is partly dissolved by undecomposed FeS. When the crude copper matte arrives in the crucible part of the dissolved iron will liberate copper from the slag according to the equation:

$$Cu_2FeSiO_4 + Fe = Fe_2SiO_4 + Cu_2$$

The remainder of the dissolved iron forms the solid compound $(Cu_2S)_2FeS$, with separation of copper, thus:

$$(Cu_2S)_2CuS + Fe = (Cu_2S)_2FeS + Cu$$

This reaction is not in contradiction with the Fournet series. The energy of combination of Cu_2S is known to be greater than that of FeS, yet the energy of combination of the sulpho-salt $(Cu_2S)_2FeS$ is apparently greater than that of $(Cu_2S)Cu_2S$. The separated copper again reacts with uncombined ferrous sulphide (a reaction accelerated by rabbling the molten matte).

$$4Cu + 3FeS = (Cu_2S)_2FeS + Fe_2$$
$$Fe_2 + O_2 + SiO_2 = Fe_2SiO_4$$

The cyclic process thus set up is only of short duration, as the small amount of free Fe is more readily eliminated by direct slagging than is the case with the free FeS, which sulphurizes the copper.

The Slagging of Nickel During the Poling of Copper to a "Set" Condition.—The operation of poling copper to a "set" condition, which follows the oxidizing fusion of high-copper matte, by rabbling and the skimming of the slag from the metal bath effects not only the removal of the absorbed SO_2, but also the reduction of the cuprous oxide (Cu_2O) dissolved in copper, by the reducing action of the gases evolved in the metal bath. With overpoled copper, according to W. STAHL (*Metall. u. Erz*, 1917, vol. XIV, pp. 202-203), it happens that the period of poling to a "set" condition is more a reduction than a gas-removal period proper. The enhanced slagging of nickel during the "dense-poling" stage is attributed by the author to the decomposition of a combination of cuprous oxide and nickelous oxide originally held in solution. As a result of dense-poling there takes place at first a reduction of free cuprous oxide, followed by reduction of some Cu_2O in combination with nickelous oxide, while the nickelous oxide itself remains unacted upon. As the nickelous oxide loses cuprous oxide, it becomes proportionately less soluble in the copper bath, until it finally liquates, combines with the acid radicals of silicates and ferrites, forming with the latter the tough, highly nickeliferous slag which is skimmed off. As a result of poling the copper to a tough-pitch condition (in which operation the layer of charcoal spread upon the metal bath assists the reduction) the remaining nickelous oxide of metal and slag is in turn reduced and the nickel retained in the metal bath.

Iron and Steel

Fatigue Failure of Boiler Plates.—E. B. WOLFF presented an exhaustive study of some obscure phenomena causing the cracking of boiler plates over the riveted seams before the Iron and Steel Institute (British), September, 1917. The cracks start as surface cracks of microscopical dimensions, each little crack being formed by itself, without reference to the position of its neighbors. Afterward, the cracks grow in length and depth and unite in longer ones, forming a peculiar stepped line. A polished and etched section through these cracks shows that the crystallites in the immediate neighborhood had not been deformed. The structure has also been found to be quite normal, no free cementite of segregations of importance having been found. All evidence pointed to a peculiar form of destruction of the surface layers of otherwise very plastic metal. Various tests showed that the material had not been sufficiently overstrained during fabrication to cause the trouble. The miniature cracks can be revealed and defective material discarded by etching the metal in 1:10 sulphuric acid for 24 hr. or more; before this treatment the cracks were covered by surface layers of oxides and were impossible of detection even after thoroughly scraping the plates. Microscopical sections through non-etched parts showed the cracks clearly. The only phenomena known where cracks of the kind described have been observed in plastic material is that known as "fatigue." Notwithstanding the severe conditions of the service, the number of alternations of stress is but few when compared to that number required to produce ordinary fatigue breaks. The author, then, by a careful study of the theory of stress in riveted joints, and the use of a special extensometer to show the distribution of stress in such joints, is able to show that the intensity of alternating stress at the parts which failed is well above the elastic limit, in which case, of course, only a comparatively few alterations are necessary to cause failure.

Composition of Rail Steel.—A test on the wear of street railway girder rails which extended over twenty-two years is reported by R. C. CRAM in the *Electric Railway Journal*, V. 51, p. 168. The Nassau Electric Railroad, Brooklyn, installed in 1895 several "soft" rails with carbon 0.28 per cent, and several "hard" rails containing what was then considered the high carbon of 0.59 per cent. The other metalloids were held as nearly equal as practicable in order that the effect of the carbon would be unmasked. Eight months later another line of rails "hard and tough" were added to the test—analyses of these rails being given in the table. At the present time the heads of all the rails seem to have worn

substantially the same amount, considering the narrow tread of the soft rail, and the shorter life of the hard and tough rail. Even so, corrosion of the rail base to such an extent as to prevent respiking has caused the replacement rather than wear on the head. The chief results are as follows:

	Soft Rails	Hard Rails	Hard and Tough
Height	7 3/16	8 35/32	8 25 32
Original head area	1.88	2.05	2.05
Amount worn, sq. in.	0.56	0.58	0.56
Per cent worn	29	28	27
Carbon	0.28	0.59	0.57
Silicon	0.026	0.056	0.234
Phosphorus	0.106	0.097	0.050
Sulphur	0.066	0.059	0.078
Manganese	0.790	0.83	0.95
Elastic limit	45,730	62,500	53,160
Ultimate strength	75,860	118,100	121,380
Elongation in 8 in., per cent.	24.3	11.9	11.5
Reduction of area, per cent.	51.6	18.4	20.0
Vertical wear, inches	0.4063	0.3437	0.3125

Potash, Nitrogen and Grease from Sewage.—X. H. GOODENOUGH, chief engineer, and H. W. CLARK, chemist, of Massachusetts Department of Health, reporting to an investigating board on the possibility of recovering fertilizing material and grease from Boston sewage by the Miles process, say that at Bradford, Leeds, Huddersfield, Oldham and Norwich, England, processes are installed treating material of much higher value than the Boston sewage. At Leeds, progress made indicates that in time they expect to arrive at an artificial process which will operate without nuisance, and make sufficient by the sale of by-products at least to pay the full cost of the disposal. In Germany the various plants erected for this purpose had one after another been abandoned as failures. Taking into account that the far richer wool-scouring wastes at Lawrence, Mass., almost go begging for utilization, there seems no present justification for spending money for a large scale experimentation with the Miles process.

In 1910 the average output from the first and second bowls of all the wool scouring machines at Lawrence amounted to 211,000 gal. per day, containing 29,000 lb. of fatty matters, 14,000 lb. of potash and 2200 lb. of nitrogen; that is, 0.14, 0.07 and 0.01 lb. per gal., respectively. At the present time two companies are faking the richest wastes amounting to about 80,000 gal. per day from the first bowls from nearly all the mills at Lawrence, and are making some profit. One company recovers only fatty matters, these being worked into lanolin. Plants for the recovery of grease from wool waste are also in successful operation at three or four other points in Massachusetts. Compared with the wool-scouring waste, the richest sewage of Boston contains 0.0006 lb. of fatty matter per gal., a very small amount of organic nitrogen, and practically no potash, the utilization of which constitutes a very difficult problem.

Analysis of Sulphur Burner Gases.—A paper on this subject was presented by F. M. WILLIAMS of Watertown, N. Y., at the recent meeting of the Technical Association of the Pulp and Paper Industry in New York. In the efficient operation of the sulphite mill, one of the most important considerations is the constant knowledge of the strength of the burner gas, SO_2, being produced. In the author's observation, the greatest variation occurs in the strength of the gas in different mills, as well as in the same mill at different periods. He has found some mills struggling along with weak acid troubles, when an analysis of the burner gas showed that they were trying to make acid with only 60 per cent SO_2 burner gas. The proper regulation of the burners by merely the appearance of the flame is much the same as trying to run a steam boiler at a definite pressure, without a steam gage.

There are two general methods of determining SO_2 in burner gases. First, by means of an instrument of the Reinsch type, in which a measured volume of gas is drawn through a standard iodine solution, which absorbs the SO_2. The principal objections to this method are that a single passage of the gas through one or two, or sometimes three, absorption bottles, does not in all cases absorb all of the SO_2 gas, and it is never possible to check the completeness of the absorption. Further, in the measurement of the complete volume of gas taken, we are dependent upon the volume of water which has passed out of the aspirator bottle, and it is necessary to apply various corrections for temperature, reduced pressure, and we always have the constant danger of error through leakage. A much more satisfactory method of analysis is the direct method, in which a measured volume of the sample is passed through a caustic potash solution in a suitable absorption pipette, after which the residue is returned to the original burette for measurement, and the operation repeated until a constant volume is obtained, the difference being SO_2 gas absorbed by the potash solution. This operation may be performed in various types of Orsat instruments.

A number of years of professional experience in sulphite mill work convinced the author of the need of a special modification of the Orsat particularly adapted to the analysis of sulphur burner gases. He has, consequently, developed a modified Orsat, known as the Williams Improved Gas Apparatus.

This instrument not only gives the percentage of SO_2 in the burner gas, but by means of the second or middle absorption tube a direct determination of the excess of air or oxygen is obtained. This is very important in burner regulation, and also in the determination of air leaks in the acid system.

In order to make the instrument equally available for the analysis of flue gases in boiler-room practice, a third or carbon monoxide tube is added, which makes it possible to determine quickly CO_2 oxygen and carbon monoxide.

In the first place, making acid with a 6 per cent gas, as against a 17 per cent or 18 per cent gas, requires about three times the length of time for makeup in a milk of lime system, with constant loss of production and a resulting acid of inferior quality. The same principle holds true in making acid in the tower system. Too weak a gas does not attack the stone readily, and it is impossible to obtain an acid of the desired quality.

On the other hand, there are troubles arising from too hot a fire, which would give a gas of sufficient richness, but will volatilize sulphur. While it is theoretically possible to obtain a gas by burning sulphur and air, of about 21 per cent SO_2, whenever this is reached in actual practice it has been the writer's observation that there has always been a volatilization of sulphur, and it would appear that a gas of from 17 to 18 per cent SO_2 is about the maximum practical working strength.

Recent Metallurgical and Chemical Patents

Electric Furnaces

Method of Starting Furnaces.—W. K. BOOTH of Chicago, Ill., patents a method of easily starting arc furnaces containing wall or hearth contacts, embedded in the lining of the furnace, whose walls, while conductive when hot, are virtually non-conductors in the cold. In starting up a cold furnace, therefore, the main electrodes rest upon the charge, and the common return in the hearth, being in effect insulated from the other electrodes, is replaced by an auxiliary electrode lowered through the roof to contact with the charge. This auxiliary electrode is manually operated, is electrically connected to the lines leading to the hearth contact, and remains in operation until the interior of the furnace becomes hot enough to allow the latter to function when the auxiliary electrode is completely withdrawn. (1,244,415; Oct. 23, 1917.)

Cooled Bottom Electrode.—MARTIN SPERLING of Essen-on-the-Ruhr, Germany (assigned to Krupps' A.-G.), patents a special design for bottom electrodes. Former construction calls for a hollow cone shape, cooled inside by a water stream. In a number of cases disastrous explosions have occurred in such electrodes due to the occasional insulation of several of the bottom electrodes from the smelting bath by pieces of clinker or refractory. The other electrodes then carry the entire load, which is in excess of the safe current density, bringing into incandescence the lowermost annular portion of the electrodes. The cooling water then gasifies with explosive violence. Sperling's construction is of low carbon iron and is illustrated in Fig. 1; it consists of a solid upper part d', a current collecting collar d^2 placed above a cooling cap D^2 and threaded electrode extension d^3, around which the water circulates. Current is thus led in through bronze plates F above the cooling water and into a solid conductor of large cross section and consequent large current capacity. Overheating is thus minimized, and contact of water and incandescent metal is impossible. (1,234,947; July 31, 1917.)

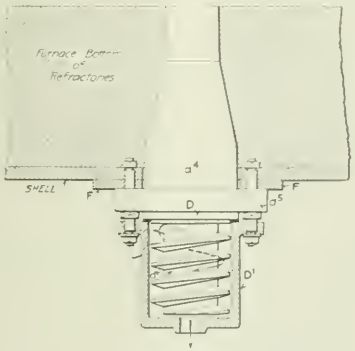

FIG. 1. COOLED BOTTOM ELECTRODE

Water Cooled Furnace Linings.—E. F. PRICE of Port Chester, N. Y., patents a method of protecting electric furnace linings from rapid destruction by air and moisture entering the fissures opened by temperature changes. Ingress of cooling fluid is prevented by laying 30-gage iron plates shingle-wise between the metal furnace bindings and the refractory lining. (1,239,214; Sept. 4, 1917.)

Low-Temperature Furnace.—I. R. VALENTINE of Schenectady, N. Y. (assigned to General Electric Co.), patents the furnace shown in cross-section in Fig. 2

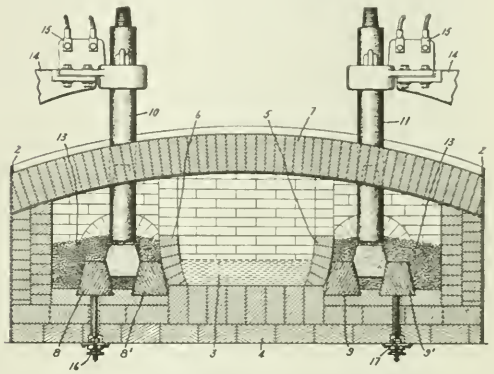

FIG. 2. LOW-TEMPERATURE FURNACE

for heating charges at relatively low temperatures in the hearth formed of carborundum brick (5 and 6). On opposite sides of the hearth are two continuous conducting prisms 8, 8', 9 and 9', supporting at intervals small graphite blocks located directly under the electrodes 10, 10' and 11, 11'. (10' and 11' are directly behind 10 and 11 and therefore not shown.) In operation current enters through electrode 11, arcs to the block below, is carried through 9 and 9' to another block, whence it arcs across to the second electrode 11'; thence back and forth through as many successive electrodes as is necessary by reason of the furnace construction. The arc is smothered by granular carbon. The central hearth is heated by conduction through the side walls and by reflection of heat rays from the arc to the roof. The use of arcs in series is flexible, easily controlled, and may use low amperage currents of high voltage. (1,242,275; Oct. 9, 1917.)

Brass Melting Furnace.—WOOLSEY MCA. JOHNSON of Hartford, Conn., patents a reverberatory melting furnace heated by a conducting grid, forming the roof of the hearth. The grid is composed of square carbon rods, acting as rafters, resting in niches in the side walls. Leading from rafter to rafter, and from the electrode blocks at either end, are short carbon bricks acting as purlins, loosely placed on the rafters. The whole may then be covered with as deep a layer of granular coke as is desirable. Some inert gas may be forced downward through the resistor toward the surface of the melt; this acts as a positive conveyor of heat, and will localize the current path near the bottom of the resistor bed by cooling the upper layers. A built-in stirrer to properly mix the melt is another feature of the invention. (1,243,416; Oct. 16, 1917.)

Hearth for Kjellin Furnace.—JAKOB FUNCK of Charlottenburg, Germany, has observed that the ordinary method of forming the trough-shaped hearth of

the Kjellin furnace, viz.: by ramming the magnesite in plastic condition around a templet, which is then removed and the mass baked by means of heating rings suitably placed in the hearth, is unsatisfactory owing to deformation suffered by the lining during the heating, and the binder at the surface is burned rather than coked, thus producing a pulverulent facing. He therefore proposes a massive iron template, which is left in place after ramming and which is electrically continuous, so that it is used as a heating element for drying and baking the new hearth. The latter is thus supported adequately during heating, and is entirely protected from the air up to the point where the template melts. The metal of the form then becomes the first charge. In case contact between hot metal and fresh lining is undesirable, the two are separated by asbestos board or other neutral refractory. (1,226,764, May 22, 1918.)

Current Control.—J. A. SEEDE of Schenectady, N. Y. (assigned to General Electric Company), patents a method of current control to electric furnaces, whereby reactance is placed in the main circuit without interrupting the current. He provides reactance devices or transformers 12 and 13 (Fig. 3) where the main fur-

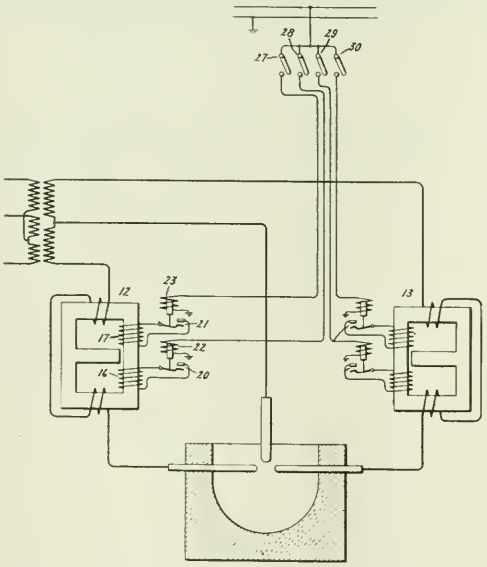

FIG. 3. WIRING DIAGRAM WITH REACTANCE IN CIRCUIT

nace supply lines form a primary winding 14 of a few turns. Secondary windings 16 and 17 may be short-circuited at 20 to 21 by solenoids 22 and 23 remotely controlled. By closing switches 27 to 30, any number of the secondary coils will be short-circuited, thus reducing the reactance in the supply mains. The larger the comparative number of turns in the secondary winding the smaller the current in that circuit and the more readily interrupted. The correspondingly increasing voltage will not be inconvenient, since the arc voltage is usually low, of the order of 100 volts, while the amperage may be many thousand. The arrangement is said to be inexpensive and reliable. (1,242,250; Oct. 9, 1917).

Miscellaneous

Increasing Capacity of Sulphuric Acid Plants.—A method for increasing the density of the sulphur dioxide entering into the manufacture of sulphuric acid is patented by MARION L. HANAHAN of Dothan, Ala. The pyrites burners used are of the ordinary construction and the gas chamber in the top is connected by a flue to a dust chamber. The flue enters the dust chamber at a point about midway between the top and bottom, and the dust chamber has an outlet near its upper end which opens into a flue. The niter oven is located between the dust chamber and pyrites burners and below the flue connecting these.

A cast iron shallow pan or container is supported on the floor near the bottom of the dust chamber. This pan is designed to hold commercial sulphur when the same becomes molten and is burning. The commercial sulphur is charged in the pan through a door cut in the side of the dust chamber opposite the sulphur container. An air pipe extends through the wall of the dust chamber and over the pan and has one or more openings to supply air or oxygen under pressure in close proximity to the sulphur in the pan. This oxygen or air is necessary to support the combustion of the sulphur in the pan to provide the sulphur dioxide. The heat necessary for melting and burning the sulphur in the pan is derived from the heat of the gases entering the dust chamber from the pyrites roaster. The sulphur dioxide produced by the burning of the sulphur in the pan in the presence of air supplied by the pipe rises and commingles with the sulphur dioxide entering the dust chamber from the pyrites roaster and the excess sodium nitrate carried by the latter gas is sufficient for the additional sulphur dioxide produced by the burning sulphur in the pan. (1,253,238, Jan. 15, 1918.)

Preparation of Alums from Clay.—LOUIS L. JACKSON of New York, N. Y., proposes to treat clay in an uncalcined condition and heat it with niter cake at a temperature of at least 150 deg. C., but at a temperature below that needed to calcine the clay and below that needed to decompose the niter cake alone. Silica, soda alum and sodium sulphate are formed, the silica being in an insoluble condition, whereas in the common process a considerable quantity of the silica is soluble. The soda alum and sodium sulphate are dissolved out with water and separated by crystallization.

Ammonium sulphate or potassium sulphate may be added in the proportion of one molecule of the sulphate to each molecule of alum, and the more sparingly soluble ammonia alum or potash alum may be obtained. While the temperature must exceed 150 deg. C., it is uneconomical to employ a temperature much above 400 deg. C., but it would be possible to get good decomposition at any temperature above 400 deg., at which all the products used and made are stable if heated by themselves. A temperature of about 350 deg. C. is preferred. (1,254,229, Jan. 22, 1918.)

Decomposing Magnesium Silicates.—LOUIS L. JACKSON of New York, N. Y., proposes to render the natural silicates, such as talc, soapstone, chrysolite, etc., soluble in acids by heating at a relatively low temperature with a large excess of caustic alkali. They are decomposed into an alkaline silicate and a silicate of magnesium which is readily soluble in acids, even in very dilute acids (for example, 1 per cent sulphuric acid), or even

diluted organic acids like acetic acid. Using twice the theoretical quantity of caustic alkali and heating even as high as 600 deg. C. for two hours, only about one-half of the soapstone is decomposed; while by using four times the theoretical amount, almost complete decomposition may be obtained in the same time at 350 deg. C., or even at a lower temperature. As the caustic alkali is recovered and used over again, there is no objection to using this large excess. (1,254,230, Jan. 22, 1918.)

Tanning Compound.—A sulphuric acid tanning compound is patented by OTTO SCHMIDT and ARTHUR ANDRES of Ludwigshafen-on-the-Rhine, Germany (assigned to Badische, Anilin and Soda Fabrik). An example of the preparation of this compound is given as follows:

"Shake together for some time, 94 parts of phenol, 22 parts of paraldehyde, and a small quantity of concentrated sulphuric acid. As reaction takes place heat is evolved, and care should be taken that the temperature does not rise above 90 deg. C.

"When the reaction is complete, add 100 parts of 97 per cent sulphuric acid and stir, while warming gently, until the reaction product is soluble in water. Take a concentrated solution of this compound, partially neutralize it with caustic soda solution and then dilute it with water until a solution of 2½ deg. Baumé is obtained. Then add ten grams of common salt to each liter of this solution and employ it for tanning. Leather is obtained which, after being treated with fat, possesses a good resistance to tearing. (1,254,364, Jan. 22, 1918.)

Potash

Potash from Tobacco Plants.—WM. H. KENNEDY and GILBERT E. BAILEY of Los Angeles, Cal., patent a process of extracting potash from the stems, ribs and leaves of the tobacco plant not ordinarily used in the manufacture of cigars, etc. The tobacco is percolated with denatured alcohol and the extracts withdrawn. The gums and resins are distilled from the residue and the residue is then roasted in the presence of charcoal to form carbonates, which are then leached with hot water to extract the potassium carbonate which is subsequently recovered. (1,253,497, Jan. 15, 1918.)

Potash from Feldspar.—EDWARD L. ANDERSON of Pittsburgh, Pa., patents an electrolytic process of obtaining potash from feldspar. Feldspar or the like material may be decomposed by electrochemical means with a relatively small amount of electrical energy by first mixing an insoluble conductive material, such as carbon or a carbon compound, so as to make the mixture a conductor of electricity. This mixture is packed in the anode compartment of a cell having a porous partition between anode and cathode compartments. The mixture is saturated with water containing five or ten per cent of hydrofluosilicic acid. The cathode compartment is filled with water. The action of the electric current is to decompose the feldspar, producing potassium hydroxide in the cathode compartment and a mixture of aluminum oxide and silica in the anode compartment. (1,253,560, Jan. 15, 1918.)

Potash from Glauconite (Green Sand).—FREDERICK TSCHIRNER of Newark, N. J., patents a process of extracting potash from green sand, which is briefly as follows: One hundred parts by weight of green sand marl (glauconite) are mixed with fifty parts of lime sand (gray calcareous marl) and thirty parts of calcium chloride. This mixture is submitted to a roasting temperature with access of air to a temperature of about 800 to 820 deg. C., care being taken to avoid a heat sufficient to form clinkers. The first result of this roasting is to dehydrate the green sand and convert the calcium carbonate largely into calcium oxide. In the presence of the calcium oxide so formed, the calcium chloride acts on the dehydrated green sand, whose ferrous salts have been converted into the ferric condition by oxidation and produces potassium chloride. The lime also reacts with any soluble ferric salts, *e. g.* chloride to produce ferric oxide and calcium chloride. This mixture after roasting can then be leached either with or without powdering and the potassium chloride can then be extracted. (1,254,450-1, Jan. 22, 1918.)

Separation of Potassium and Sodium Salts.—JOHN R. MACMILLAN of Niagara Falls, N. Y., patents a process of recovering high grade potash salts, which is assigned to the Niagara Alkali Co. He employs the differential solubilities of the carbonates and bicarbonates to give a separation in a single operation. The solution (with or without preliminary separation of normal sodium carbonate by cooling to 5 deg. C. to 0 deg. C.) is treated with carbon dioxide gas at a temperature of 20 to 30 deg. C. This converts the alkalies into bicarbonate and the sodium is precipitated. The solution is then cooled to 1 deg. to 5 deg. C., when crystals of pure potassium bicarbonate will be formed. These crystals when dried, with ordinary washing, contain, ordinarily, not over 2 to 4 per cent sodium bicarbonate and under 1 per cent sulphates and chlorides even in the case of solutions containing much sulphate and chloride. (1,254,521, Jan. 22, 1918.)

Potash from Glauconite (Green Sand).—WALTER GLAESER of Fullerton, Pa., patents a process of treating glauconite, which is assigned to the Potash Extraction Corp. of New York. The finely ground green sand is mixed with about sixty per cent of its own weight of calcium chloride and 5 per cent of coke, and the mixture heated to 270 deg. C., to drive off the moisture. Air is excluded in this operation. The mixture is next heated to 800 deg. C., in a non-oxidizing or reducing atmosphere. In this step potassium chloride and a silicate of iron and calcium are formed. (1,254,676-7, Jan. 29, 1918.)

Potash from Feldspar.—A process of producing alkali carbonates, containing small amounts of alkali hydrates, from alkali rocks is patented by HARRY W. CHARLTON of New York. In treating feldspar from 3 to 6 parts of same is digested with 7 to 2 parts of a mixture of lime and calcium carbonate in 44 to 26 parts of water at pressure above 200 lb. and corresponding temperatures. Most of the potash is thereby extracted. The residue is white and is used in making brick. (1,256,295, Feb. 12, 1918.)

Electric Furnaces in Canada.—Discussing the subject of electric smelting in an address at the recent annual meeting at the Commission of Conservation, Sir Clifford Sifton said that there are, at the present time in Canada, 32 Heroult electric furnaces and 22 of other types—54 furnaces in all, with a capacity of 173,000 tons of iron and steel, 50,000 tons of ferrosilicon, and 8000 tons of other ferroalloys per annum.

A New Method of Microscope Illumination

By Alexander Silverman*

FEELING the need for an illuminator which would furnish diffused light for examination of opaque objects and which could be lowered into hollow objects, the writer has devised the following microscope accessory:

A circular tube containing a tungsten filament is separably attached to a ringlike holder (Fig. 1), which by means of three centrally protruding fingers, controlled by springs, is clamped to the microscope objective (Fig. 2). The holder may be raised or lowered to modify the quality and intensity of the light. The lamp is made of colorless or blue (daylight) glass having a white reflector on the upper portion, and in models in use requires 0.7 ampere and 6 volts. It can be connected to a 110-volt lighting circuit with a resistance in series, or to a storage battery system.

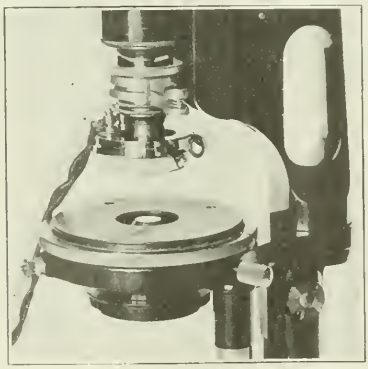

FIG. 2

The new illuminator[1] possesses the advantage that it travels with the microscope tube and is always in position, even though the microscope may be moved about. The lamp possesses the additional advantage that it shows details not visible when vertical illuminators are used. Fig. 3 shows a specimen photographed with a vertical illuminator; Fig. 4 the same photographed with the new illuminator.

Examination of the photomicrographs shows that those portions which are dark by vertical illumination are light in the new prints. This possesses the advantage that for lantern slides one can use the negative directly for comparison with earlier work done with vertical illuminators. The definition of the image obtainable by the new process should result in additional important developments in the field of metallography. It has been employed successfully with a 60-mm. objective for photographic purposes where other forms of illuminators were unsatisfactory and serves well for powers up to 4 mm.

FIG. 1 FIG. 3 FIG. 4

By varying the resistance one can obtain different light intensities for special purposes. By adjusting the position of the lamp almost any desired contrast is possible. The light is steady, so clear images are obtainable. Any one who has used an arc lamp realizes the difficulty experienced in adjusting the light in photomicrography.

The illuminator is so constructed that it can be used with any type of nosepiece or objective, including the new short type. It is only necessary to clamp it to the objective by means of the spring clamp.

The writer's attention has been called to the fact that in vertical illumination the eye is strained by rays passing up and down through the inclined disk and because the observer has to look through this additional obstruction. The light spot due to the source of illumination also causes strain. In the new process the light source surrounds the objective and a soft light travels through the tube in one direction.

[1]Patents applied for.

Muscle Shoals Dam Authorized.—An order has been signed by President Wilson authorizing the construction of a water-power dam at Muscle Shoals which will form a part of the government's nitrogen fixation plants and will cost $50,000,000. The Alabama Power Co. gave the government the dam site without cost.

Improvement in Sintering Blast Furnace Flue-Dust

A NEW and improved design of the Dwight and Lloyd sintering machine, which is shown in the accompanying photographs, was recently completed for the Carnegie Steel Company, New Castle, Pa., and is to be used there for sintering blast-furnace flue-dust. This new machine has an active grate surface 42 in. wide and 57 ft. 4 in. long and a sintering capacity $2\frac{1}{4}$ times that of the present standard Dwight and Lloyd machine.

This new large sintering machine contains a number of important improvements which are the result of the experience gained by the American Ore Reclamation Company in the operation of the many standard Dwight and Lloyd sintering machines which have been installed in plants in the last six years.

The standard Dwight and Lloyd machine heretofore used has an active grate surface 42 in. wide and 25 ft. 6 in. long and the lower strand of pallets rolls by gravity along an inclined track back to the driving sprocket wheels. The much greater length of the new machine makes the use of a gravity return undesirable and the lower strand of pallets is, therefore, positively driven along the lower track by sprocket wheels at the discharge end. These discharge-end sprocket wheels are driven in synchronism with the driving-end sprocket wheels as shown in Fig. 1. This synchronous drive insures that the empty pallets are returned to the driving sprocket wheels at the same rate of speed as that of the pallets on the upper strand.

On this new large machine, sliding friction between the pallets and the wind-box tops is eliminated by carrying the weight of the loaded pallets on wheels running on rails. The pallet wheels are fitted with renewable Shelby steel bushings and have large oil spaces that carry a month's supply of grease. The sprocket-wheel teeth drive against tooth surfaces cast in the frame of the pallet and not against the pallet wheels, thus allowing the pallet wheels to properly perform their rolling function around the curved tracks at the drive end.

All of the gears and the sprocket-wheel teeth on the new machine are made of steel castings. All gears and

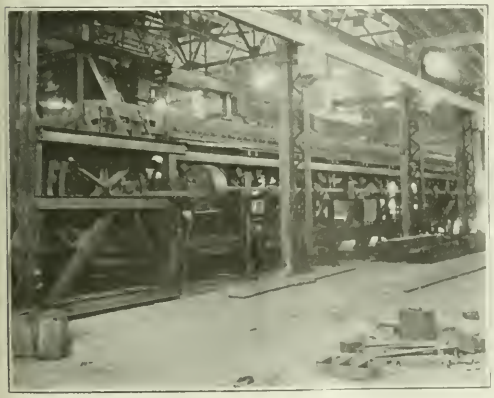

FIG. 1. GENERAL VIEW—PALLETS LOADED WITH PIG IRON FOR TESTING PURPOSES

FIG. 2. DRIVE END

the shaft couplings are wholly enclosed in heavy sheet-steel housings. The sprocket-wheel teeth are removable and are machined in jigs so that they are interchangeable, and when worn may be replaced without tearing down the larger members of the drive. The driving pulley is fitted with a cast-iron break-pin to prevent accidental injury to the driving mechanism.

An important feature of the new machine is the use of seal bars on the pallets which automatically maintain air-tight joints between the pallets and the tops of the wind boxes. These seal bars are made very light, and by their own weight bear on the finished surfaces of the wind-box tops and also fit against the finished sides of the pallet slots in which the bars are hung.

The first one of the new machines was thoroughly tested under full-load conditions, which were obtained by loading the upper strand of pallets with 20 tons of pig iron, as shown in the photograph. In all of the tests the machine ran with a notable degree of smoothness and the seal bars made a tight joint. The horsepower readings taken during the tests show that the various improvements have been fully effective in reducing the driving load.

The fully loaded machine as set up for the test required 12^{3}_{4} hp.

Based on the performance of the smaller machines now in service, the capacity of the new large machine, when sintering various materials, is estimated to be as follows:

	Tons Sinter per 24 hr.
Flue-dust	300 to 350
Pyrites cinder	375 to 450
Magnetic concentrates	450 to 550

Heavy Hauling with a Tractor

Some recent interesting applications of the tractor in industrial plants are shown in the accompanying illustrations. They suggest many other possible similar uses. Fig. 1 shows a tractor on transfer-buggy work at the Lake Erie Iron Company, Cleveland, Ohio. Fig. 2 shows an engine base casting weighing 2500 lb. on the way from the foundry to the machine shop. Fig. 3 shows 20,000 lb. of steel filings and turnings being moved by the tractor, which is on steel floor plates at the Van Dorn Iron Works, Cleveland, Ohio.

FIG. 1. TRANSFER BUGGY WORK. LAKE ERIE IRON CO., CLEVELAND

FIG. 2. ENGINE BASE CASTING ON WAY FROM FOUNDRY TO MACHINE SHOP. WEIGHT ABOUT 2500 LB.

FIG. 3. 20,000 LB. STEEL FILINGS AND TURNINGS; TRACTOR ON STEEL FLOOR PLATES PUSHING TRANSFER BUGGY. VAN DORN IRON MILLS, CLEVELAND

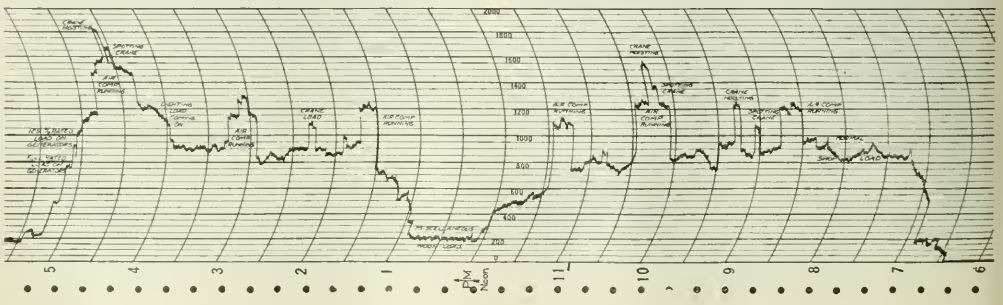
The tractors were made by the Cleveland Tractor Company, Cleveland, Ohio.

Value of Graphic Records in Management

The accompanying record is a representative piece from an instrument installed in a manufacturing plant by the Esterline Co. of Indianapolis. It shows the value of graphic records.

The company generates its own electricity for light and power. The steady plant load has grown until it is a full and efficient load for the boilers and the two generating sets installed. In addition they have several pieces of heavy equipment, operated only occasionally, which throw an excessive and damaging overload on the power plant. Hence the plans for a new addition to the plant.

The record from the graphic instrument, picturing the output of the plant at all hours of the day, showed that while the peak loads thrown on the plant



were greatly in excess of its capacity, they are of short duration, and measured in kilowatt-hours do not call for sufficient energy to warrant the installation of additional equipment. Actual figures showed that the company would make money by carrying the steady load on their power plant, and purchasing the peaks from the local power company.

Personal

Mr. H. A. BRASSERT, who has been connected with the U. S. Steel Corporation since its organization, has resigned his position as assistant general superintendent of the Illinois Steel Co. at South Chicago in order to devote himself to his personal interests. As vice-president of the Miami Metals Co. and subsidiary companies he will have charge of their operations in the production of ferromanganese. Mr. Brassert will also act as consulting engineer for Freyn and Company, engineers and contractors. He will associate himself with Messrs. Francis H. Hardy and Chester D. Tripp, in the firm of Brassert, Hardy & Tripp, to act in a consulting and advisory capacity on commercial and operating problems in the iron and steel and affiliated industries. Mr. Brassert will remain in Chicago, with offices in the Peoples Gas Building.

Mr. H. P. CURTISS has been appointed New England representative for the Clarage Fan Company, Kalamazoo, Mich., with offices at 120 Milk Street, Boston.

Dr. W. F. FARAGHER has resigned his position as research chemist for the Alden Speare's Sons Co. to become Senior Fellow at the Mellon Institute in Pittsburgh. He will work on crude petroleum.

Mr. LEON O. HART has been elected treasurer and a director of the Driver-Harris Co., Harrison, N. J. Mr. Hart has been with the company since 1908 and since March, 1917, has been assistant treasurer.

Mr. HENRY C. HOWARD, JR., treasurer and chief chemist, Charles A. Newhall Co., Inc., Seattle, Wash., has joined the 30th Engineers and is now stationed at Fort Myer, Va. Mr. Howard has specialized in electrochemistry and had recently developed a process for the manufacturing of potassium per-chlorate, the potassium salts being derived from kelp. The process is now being operated on a commercial scale in Seattle.

Dr. I. F. LAUCKS, formerly of Falkenburg & Laucks (dissolved), has opened his new laboratory in Seattle. This laboratory will specialize in the examination of materials of commerce originating in this territory and passing through the port of Puget Sound. The commerce of this port has increased so rapidly in the last few years as to justify the establishment of such a laboratory. A fully equipped metallurgical laboratory is also maintained.

Recent changes have been made in the staff of the Ohio & Colorado Smelting & Refining Co., at Salida, Colo., as follows: E. H. LAWS has resigned as superintendent; A. T. THOMPSON has been appointed superintendent; E. J. BRUDERLIN, assistant superintendent; W. H. NANCE, superintendent of roasting department; J. H. FINGER, chief chemist.

Dr. E. H. LESLIE has resigned from his position as chief chemist of the General Petroleum Corporation of Los Angeles and has assumed new duties as technical adviser to the sales department of the U. S. Industrial Alcohol Company and the U. S. Industrial Chemical Company. He will be located in their main offices at 27 William Street, New York City.

Mr. LOYALL A. OSBORNE of New York, vice-president of the Westinghouse Electric & Manufacturing Company and Chairman of the Executive Committee of the National Industrial Conference Board, has been appointed, by the Secretary of Labor, a member of a committee on industrial peace during the war.

This committee, which consists of five representatives of employers, five labor leaders, and two public men, will provide a definite labor program in order that there may be industrial peace during the war, thus preventing interruption of industrial production vital to the war.

The Worthington Pump and Machinery Corporation has made a number of appointments in its staff, effective March 1, as follows: JAMES E. SAGUE, vice-president, in charge of engineering and manufacturing; LEON P. FEUSTMAN, vice-president, in charge of general commercial affairs, including contracts, prices, purchases, traffic, etc.; FRANK H. JONES, vice-president, in charge of sales; WILLIAM GOODMAN, assistant to vice-president; WILLIAM SCHWANHAUSSER, chief engineer; EDWARD T. FISHWICK, general sales manager; CHARLES E. WILSON, assistant general sales manager. The offices of the above will be at 115 Broadway, New York. NEIL C. LAMONT, works manager, Laidlaw Works, with offices at the works, Elmwood Place, Cincinnati, Ohio.

Mr. E. GYBBON SPILSBURY left New York on Feb. 24 for Cuba and expects to be absent about six weeks. The offices of the E. G. Spilsbury Engineering Co. have been moved from 45 Broadway to 29 Broadway, New York.

Mr. POPE YEATMAN has been placed in charge of the nonferrous metals department of the Raw Materials Division of the War Industries Board, succeeding Eugene Meyer, Jr. Mr. Meyer remains a member of the Raw Materials Division, but for the present is engaged on special work for the Secretary of War.

Book Reviews

STANDARD TABLE OF ELECTROCHEMICAL EQUIVALENTS AND THEIR DERIVATIVES, WITH EXPLANATORY TEXT. By *Carl Hering* and *F. H. Getman*. Duodecimo. 130 pages. Leather binding. Price, $2.00. New York: D. Van Nostrand Company.

The tables are based on 96,494 coulombs as the value of the Faraday, and on the atomic weight of oxygen 16. They give for each element, for its usual valence, or for its more usual valences if it has several, the milligrams per coulomb, coulombs per milligram, grams per ampere-hour, ampere-hours per gram, pounds per 1000 ampere-hours, and ampere-hours per pound. For elements which frequently change their valence in electrolysis, these data are also given for a change of valence of unity. These tables are very carefully calculated, and the figures are probably the most reliable now in print. Dr. J. W. Richards contributes a supplementary tabulation of the valences of the elements in their various combinations, as bases and acids; the values given are the practical or apparent valences, irrespective of any interpretation involving structural formulas. The term "non-valent" is used for elements forming no known combinations; valence zero is reserved for all free elements, not in combination, as is logically required by Faraday's Law.

The remainder of Part I deals with illustrations of calculations based on the electrochemical equivalents. They are carefully explained, and will teach the reader much fundamental electrochemistry. The chemical terms are here at times used loosely (*e.g.*, the *atomic* weight of SO, is spoken of), and the chemistry involved in explaining the electrolysis of 2 Cu Cl to form Cu and Cu Cl, is decidedly vague: it is certainly wrong even to suggest that one of the two molecules of Cu Cl is changed to Cu Cl, at each electrode.

Part II consists of 35 pages of explanation of electrolysis, and a short statement of the electronic theory. Some of the statements in this part are too general (*e.g.*, "Fused salts form practically the only exception to the rule that pure chemical compounds are non-conductors of electricity" —this ignores the conducting oxides, sulphides, etc., and all the pure materials conducting at high temperature, such as Mg O, etc.). The term "electrolyte" is used very vaguely, sometimes for the undissolved solid salt, sometimes for the salt in solution, sometimes (correctly) for the solution, and once for the solvent. Greater precision in this regard is certainly desirable.

Two appendices, written by Dr. Hering, deal with "Valence" and "Elementary Principles of Chemical Reactions and Calculations." The handling of + and — valences at

anode and cathode is carefully worked out, and is worthy of the attention of chemical philosophers; the system should be adopted, for it is clear and logical. Electrolytically, the elements as they are set free from combination by the reducing effect of the current at the cathode or its adducing effect at the anode, must be regarded as having their valences reduced or adduced to zero, in each case. This conclusion is a categorical imperative. The authors deserve our thanks for the time and effort they have put on what is certainly a useful book.

* * *

REPORT OF THE ROYAL ONTARIO NICKEL COMMISSION. With Appendix. Octavo (15 x 24 cm.), xlviii + 646 + 218 (appendix) pages. Printed by order of the Legislative Assembly of Ontario. Toronto, 1917.

The commissioners producing this report were G. T. Holloway of the Royal College of Science, London, and vice-president of the Institution of Mining and Metallurgy; W. G. Miller, provincial geologist of Ontario; McGregor Young of Toronto, and T. W. Gibson, Deputy Minister of Mines, Toronto. We name these gentlemen because they have done a splendid piece of work and deserve personally the thanks of the metallurgical fraternity as well as the gratitude of the Canadian government.

The first 48 pages are a summary and conclusions. The two principal questions to be determined were: (1) Can nickel be economically refined in Ontario? (2) Are the nickel deposits of Ontario of such a character that this Province can compete successfully as a nickel producer with any other country? The commissioners had no hesitation in answering both these questions in the affirmative. Their studies, however, on which these conclusions were based, and which are set forth *in extenso* in their report, embraced (a) The occurrence, deposit, supply, mining, products, by-products and alloys of nickel in Ontario and elsewhere, together with the present, probable and possible uses thereof. (b) The smelting, refining, manufacture and treatment of nickel, its ores, products, by-products and alloys, in Ontario and elsewhere. (c) The demand and market for nickel, its ores and products, by-products and alloys. (d) The probable development and requirements of the nickel and allied industries in Ontario. (e) Suggestions upon a just system of taxation of nickel lands, ores, products and industries in Ontario.

A further review of the book is unnecessary: we need only to state that the commissioners have actually fulfilled this amazing program, and have done it handsomely. All the previous treatises on nickel put together do not contain as much valuable information concerning this subject. It is absolutely comprehensive and complete. (For instance, 56 pages of Bibliography of Nickel.) We congratulate them sincerely on their fine work.

As a practical question it remains to state how the report is distributed.

Current Market Reports

The Iron and Steel Market

Traffic conditions, as affecting the iron and steel industry's operations, have continued to improve, but there is no chance of March making a new record for production as it frequently does. The railroads can clear their congestion and resume normal operations, only slowly, while apart from that is the fact that the exigencies of war, and particularly our share in provisioning our Allies, requires much special movement of freight, interfering with ordinary traffic movement. In particular the movement of foodstuffs from Chicago and other far interior points to seaboard has in the past few weeks tied up a great deal of transportation capacity.

Pig iron production in the fore part of March was at the rate of about 33,000,000 tons a year, while the productive capacity is at least 43,000,000 tons. The restriction in output was wholly by reason of insufficient coke supplies. The by-product ovens at blast furnaces have not been fully supplied with coal, although their supplies have probably been 90 per cent., against 75 per cent or less in January, when the worst conditions obtained. In various districts there has been a shortage of beehive coke owing to insufficient movement, and this influence has been most pronounced in the case of Connellsville. In February Connellsville coke shipments rose to a rate of nearly 300,000 net tons a week, but the requirements of the furnaces regularly tributary to the region are fully 375,000 tons a week. On the assumption that pig iron production is 10,000,000 tons a year under capacity, the shortage of Connellsville coke accounts for about two-fifths of the total restriction.

There is no shortage of pig iron and there has been none since early in the year, the condition being quite different from that obtaining in 1917, when at practically all times the operation of steel works was restricted by an insufficiency of pig iron. The only reason the light supply of pig iron cannot be regarded as representing a shortage is that the steel mills are greatly restricted in shipping their finished product. The shortage of cars continues, while few of the embargoes have been removed, and railroad permits, to ship into or through embargoes, are not granted with much more freedom than formerly. The steel mills shipped finished products in January at the rate of about 60 per cent of capacity. February showed an average rate of about 65 per cent, and at the middle of March shipments are averaging 70 per cent or a trifle more. Meanwhile there is a little accumulation of pig iron, also a little accumulation of ingots. Production of finished steel is slightly less, on an average, than the shipments, as the mills are making an effort to reduce stocks, which at many mills are an encumbrance.

Commercial Demand

As to any appraisal of the market situation and prospects a serious obstacle is the fact that trade currents and influences, usually an object of close scrutiny, cannot be observed at this time. Buyers have a large tonnage on mill books, much of the tonnage long overdue, and this would naturally make them indisposed to make additional purchases. Uncertainty as to prices causes an indisposition to buy for far forward deliveries and thus the volume of buying does not furnish the usual market index. The willingness of many buyers to accept shipments cannot be tested because they are embargoed. Technically the position is that the mill cannot ship by reason of traffic conditions, but one does not know that if traffic conditions were suddenly made normal the consumers would continuously accept the larger shipments that would then be made. Many consumers, perhaps, are hiding behind embargoes and not disclosing their real situation as to the amount of steel they need.

Appearances, so far as they can be observed, are that the strictly commercial demand for steel is extremely limited. Ordinary commercial work is largely suspended. Quite a distorted view may be obtained, however, by observing merely that requirements for steel entirely dissociated from prosecution of the war promise to be very light, because one activity after another transfers itself from the commercial class to the war class. The largest single customer of the steel industry are the railroads, but the buying of railroad material is now a government activity, and large orders are to be placed. Oil development and transport, normally consuming a great deal of steel, is now regarded as a war activity, and so with coal mine equipment and a host of things.

Steel for war has fallen broadly into two categories, the steel that is needed only once, for certain descriptions of equipment, and the steel that will be needed in a steady stream while the war lasts. In the former class, for instance, is steel for building and equipping army cantonments and shipyards, while in the latter class is steel for guns, shells and ships. Demands in the former class are playing out, while demands in the latter are increasing.

On the whole there is very considerable reason for doubting whether there will be enough demand for steel to enable the industry to operate at 85 or 90 per cent of its capacity. As long as traffic conditions prevent the industry from operating at the rate desired the extent of the requirements is not disclosed. At capacity, the steel industry can produce approximately 3,000,000 gross tons of finished rolled steel a month. With fair traffic conditions, but with some labor shortage and troubles of other descriptions, it ought

to be able to produce 2,500,000 tons a month without much difficulty. It is quite impossible to make up any budget of war and near-war requirements in steel that will total any such tonnage, but this is all theory, and the practical operation of the market in the next few weeks will probably make some definite disclosures.

The present set prices for iron and steel, extended in their operation to March 31 by the announcement of December 28, will probably be reaffirmed by the War Industries Board, either to the end of the year, as desired by the producers, or for an indefinite period. At a meeting of representative manufacturers held in New York Friday, March 1, the matter of conferring with the War Industries Board was left to the Institute committee, without specific instructions. Some interests would prefer slight modifications in the schedule, but the preponderating sentiment is that the schedule is a fairly well balanced one, and as it is reasonably well known that the War Industries Board would be indisposed to advance any prices the trade's natural preference is that no change should be made. It is important to observe that the strategic position of the War Industries Board is quite different from the one it occupied last summer when it sought a voluntary agreement with the producers. At that time ordinary commercial demand was considered an important factor, and this had to be considered when the government had no legal authority as to prices except in the case of its own purchases. At the present time the government purchases greatly preponderate, and at any time the government could set prices, with full legal authority, on this class of business. The result of the situation is that the War Industries Board occupies a very strong position.

Chemical Market

Coal Tar Products.—While the inquiry was slightly improved, there was not a great deal of business passing during the interval. The scarcity of some of the important products on the list has resulted in an advance in prices on several items.

Benzol.—The demand has improved slightly and, while there is a little more business passing than during the past few months, the movement continues below normal, with prices unchanged.

Phenol.—Offerings were light, but the demand is in like order, and prices are slightly firmer.

Toluol.—The Government is not permitting the release of any large quantities of material; second hands, however, are offering small quantities and are exacting high prices.

Naphthalene.—The inquiry has improved considerably of late, with prices higher and the supply considerably below normal.

Aniline Oil.—Prices hold steady, although the demand of late has fallen off somewhat.

Beta Naphthol.—Has been fairly active, but the production is sufficient to cover requirements of the trade, and prices are unchanged.

Dimethylaniline.—Has been advanced in price and some producers are offering only on contract.

Ortho Nitro Toluol.—The scarcity of toluol coupled with an increase in the buying inquiry has caused leading producers to advance prices.

Para Nitro Toluol.—The demand is not heavy and, despite the fact that raw material is scarce, prices are unchanged.

Benzaldehyde.—The scarcity of raw material has resulted in the restriction of production, and prices are advanced, with only a few producers offering.

Benzoate of Soda.—Remains in speculative hands and prices are fluctuating in a nervous way according to ideas of holders based on the demand.

Heavy Chemicals.—The general trend of values under this heading has been downward during the past two weeks, due principally to the lack of actual consuming demand and the difficulty of securing export licenses and the resulting curtailment of trade.

Caustic Soda.—A marked decline on caustic values has been noted during the past two weeks, and sales have occurred as low as 4.25c. for material from New York store. The production continues on a large scale and, due to the impossibility of exporting the usual amounts, the domestic output at the moment is probably two or three times in excess of the domestic production. For shipment from works there have been special sales at 4c., works, but this figure is low and fractional advances have been quoted for distant delivery. There has been but a very limited inquiry for distant deliveries.

Soda Ash.—The movement has been unimportant, and prices are on about the same level as when we last reported. There has been some inquiry for export barrels and for dense ash, but the inquiry has been from comparatively few sources.

Copper Sulphate.—The market has improved under a better inquiry and there have been sales of Nichols brand at 9⅜c. and 9½c. The outside brands have been selling at prices ranging from 9c. to 9¼c.

Cyanide of Soda.—A weak market continues, and there have been offerings as low as 36c., although the general trade is asking 42c. and 45c. An increased output has been the cause of the lower situation.

Yellow Prussiate of Potash.—Offerings have been more liberal, and there have been important sales as low as $1.22, although $1.25 is more generally quoted. The buying season for prussiates is now approaching and improvement is looked for. Red prussiate has been offered at $2.80 to $2.90.

Prussiate of Soda.—Important business has passed at 37½c., and there are sellers now at 38½c. and 39c.

Chlorate of Potash.—An extremely dull situation has prevailed and the product has been difficult to move for either export or domestic account. It is reported that there have been offers as low as 28c., although this was an export lot for which a license could not be secured. Sales, however, of ordinary amounts have occurred at 34c. for crystals ground free of charge.

Bleaching Powder.—A lack of demand has prevailed and there have been offers of material from store at prices ranging from $1.85 to $2.00. From works, however, makers quote $2.25.

Bichromate of Soda.—The buying flurry has continuedl and there have been a number of important sales at prices ranging from 23c. to 24c. at various points. The production has been well sold and the product has passed into second hands.

Glycerin.—Sales during the last ten days have probably totaled close to 200 cars of dynamite at prices ranging from 65½c. to 66½c. The explosives manufacturers have entered the market in a big way and at the moment of writing are still bidding at 66c. with refiners holding at 68c.

Acetic Acid.—Stocks have dwindled and there are very few offers reported, particularly on the lower tests. The 28 per cent material has been sold at 6½c. Chicago, but at the moment of writing sellers are asking 8½c. rolling. Glacial acid is offered at 37c., carboys extra.

Sulphuric Acid.—The movement has been much relieved and tank cars have been coming through more satisfactorily. While considerable business was done early in the interval at $90.00, drums included, f.a.s., there are offers now of the 66 degree brimstone material at $75, drums inclusive, f.a.s. In seller's tanks there are offers at $40.00, seller's tanks, seller's works. Some 60 degree acid has been offered at $23.00, buyer's tanks, seller's works.

Arsenic.—The Food Administration has fixed a price of 9½c. at which white arsenic should be sold. As a consequence of this situation the trade is much unsettled as they are somewhat uncertain as to the desires of the Administration. Most of the trade have withdrawn offers but some material is available at 17¼c.

Aqua Ammonia.—Supplies have been almost eliminated from the market. Despite the fact that the Government has fixed a price of 8½c. for the 26 degree material there has been some trading of a few drums practically daily at prices ranging from 19c. to 23c.

Non-Ferrous Metal Market

Monday, March 11.—There have been no startling developments in these markets. Tin continues to be very scarce for prompt supplies and futures have again advanced.

Copper.—Consumers experienced little difficulty in obtaining adequate supplies during the month of February and there seems to be enough copper for present needs. The refineries are watching the labor situation very closely and

are experiencing some difficulty in holding men owing to higher wages being offered elsewhere. There is a belief that a higher price will be recommended for copper in June when the subject comes up for discussion again. Some of the smaller producers are unable to make a profit at present prices. The price for all grades continues at 23.50 for producers and 24.67½ for jobbers.

Tin.—In February 1280 tons of tin arrived at Atlantic ports and on March 1, only 197 tons was in stock at Atlantic ports. At Pacific ports the arrivals for February were 1548 tons. Total deliveries were 3398 tons. No Straits tin is offered for shipment before June. Banca tin is available at 75 cents for March shipment and 74.50 for April. English, Lamb & Flag is held at 81.50 for March shipment. A little 99 per cent tin is offered on spot at 84 cents.

The monthly statistics compiled by the New York Metal Exchange are interesting and are given as follows:

Tons of 2240 lb.

Straits			
Shipments during	Feb., 1918.	Jan., 1918.	Feb., 1917.
To Great Britain	*1,000	*1,500	4,264

	Feb. 28,	Jan. 31,	Feb. 28,
Total visible supply	1918. 17,034	1919. 16,949	1917. 19,627

* Estimated.

Lead.—The Trust price of lead was again raised $5 per ton to 7¼ cents on Feb. 26. The market at the time of writing was dull and the premium for prompt metal had disappeared in the West. Independents are asking 7⅝ to 7½ cents.

Spelter.—There has been a fair demand for spot spelter and sales have been made as high as 8¼ cents New York. At Western points the price has been as low as 7½ cents.

Aluminium.—The President has approved an agreement made between the War Industries Board and the producers of aluminium fixing the price of aluminium at 32 cents per lb. in 50 ton lots f.o.b. shipping point, 98 to 99 per cent material. The conditions of the agreement are: First, that the producers will not reduce the wages now being paid; second, that they will sell to the allies, to the public, and to the Government at the same price; third, that they will take the necessary measures, under the direction of the War Industries Board, for the distribution of the aluminium to prevent it from falling into the hands of speculators, who might increase the price to the public; and, fourth, that they pledge themselves to exert every effort necessary to keep up the production of aluminium so as to insure an adequate supply so long as the war lasts.

Radium.—The price of radium is understood to be in the neighborhood of $2,800,000 per oz. at present. Before the war it sold at $1,000,000 per oz., although it was produced at a considerably lower figure, but not for sale, by the Bureau of Mines in their experimental plant in Colorado.

Hydrochloric, C. P.	lb.	.08 — .08½
Hydrochloric, 20 deg.	lb	.02½— .03
Hydrochloric, conc., 22 deg.	lb.	.03 — .03½
Hydrofluoric, 30 per cent, in barrels	lb.	.06 — .06¼
Lactic, 44 per cent	lb.	.15 — .15½
Lactic, 22 per cent	lb.	.05½— .06½
Nitric, 36 deg.	lb.	Nominal
Nitric, 42 deg.	lb.	.09½— .09½
Oxalic, crystals	lb.	.44 — .45
Phosphoric, 47-50 per cent crude	lb.	.07½— .10
Phosphoric, ref. 50 per cent	lb.	.26 — ...
Picric	lb.	Nominal
Pyrocatlic, resublimed	lb.	3.10 — 3.15
Sulphuric, 60 deg.	ton	... — 35.00
Sulphuric, 66 deg.	ton	40.00 — 45.00
Sulphuric, oleum (Fuming), tank cars	ton	77.00 — 80.00
Tannic, U. S. P., bulk	lb.	1.30 — 1.35
Tartaric, crystals	lb.	.75 — .78
Tungstic, per lb. of W	lb.	1.80 — 1.90
Alcohol, sugar cane, 188 proof	gal.	4.93 — 4.95
Alcohol, wood, 95 per cent	gal.	1.35 — 1.38
Alcohol, denatured, 180 proof	gal.	.70 — .72
Alum, ammonia lump	lb.	.04 — .04¼
Alum, chrome ammonium	lb.	.18½— .19
Alum, chrome potassium	lb.	.20½— .22
Alum, chrome sodium	lb.	.12½— .13
Alum, potash lump	lb.	.08¼— .09½
Aluminium sulphate, technical	lb.	.01¾— .02½
Aluminium sulphate, iron free	lb.	.02¾— .03¼
Ammonia aqua, 26 deg. carboys	lb.	.24 — .25
Ammonia, anhydrous	lb.	Nominal
Ammonium carbonate	lb.	.11 — .12
Ammonium nitrate	lb.	(Fixed price) .14
Ammonium, sulphate domestic	lb.	.07½— .07¾
Amyl acetate	gal.	5.00 — 5.25
Arsenic, white	lb.	.17¼— .17½
Arsenic, red	lb.	.65 — .70
Barium carbonate, 99 per cent	ton	80.00 — 90.00
Barium carbonate, 97-98 per cent	ton	65.00 — 67.00
Barium chloride	ton	65.00 — 85.00
Barium sulphate (Blanc Fixe, powder)	lb.	.03¾— .04
Barium nitrate	lb.	.08½— .08¾
Barium peroxide, basis 70 per cent	lb.	.30 — .32
Bleaching powder, 35 per cent chlorine	lb.	.02 — .02½
Borax, crystals, sacks	lb.	.07¼— .08¼
Brimstone, crude	ton	Nominal
Bromine, technical	lb.	.75 — ...
Calcium, acetate, crude	lb.	Nominal
Calcium, carbide	lb.	.14¼— .14½
Calcium chloride, 70-75 per cent, fused, lump	ton	23.00 — 27.00
Calcium peroxide	lb.	1.60 — 1.70
Calcium phosphate	lb.	.34 — .35
Calcium sulphate 98-99 per cent	lb.	.09 — .09½
Carbon bisulphide	lb.	.08 — .10
Carbon tetrachloride, drums	lb.	.15½— .16
Carbonyl chloride (phosgene)	...	... — ...
Caustic potash, 88-92 per cent	lb.	.84 — .85
Caustic soda, 76 per cent	lb.	.04¼— .04½
Chlorine, liquid	lb.	.15 — .18
Cobalt oxide	lb.	1.60 — 1.65
Copperas	lb.	.01¼— .01½
Copper carbonate	lb.	.30 — .40
Copper cyanide	lb.	.75 — .78
Copper sulphate, 99 per cent, large crystals	lb.	.09½— .09¾
Cream of tartar, crystals	lb.	.59 — .61
Epsom salt, bags	lb.	.03¼— .03½
Formaldehyde, 40 per cent	lb.	.19½— .20
Glauber's salt	100 lb.	1.75 — 2.00
Glycerine, bulk, C. P.	lb.	.68½— .69
Iodine, resublimed	lb.	4.25 — 4.35
Iron oxide	lb.	.13 — .15
Lead, acetate, white crystals	lb.	.17 — .18
Lead arsenate (Paste)	lb.	.15 — .18
Lead nitrate	lb.	.15 — .16
Litharge, American	lb.	.09½— .11½
Lithium carbonate	lb.	1.50 — 2.00
Manganese dioxide, U. S. P.	lb.	.70 — .75
Magnesium carbonate, technical	lb.	.10½— .11
Nickel salt, single	lb.	.12½— .13
Nickel salt, double	lb.	.12 — .14
Phosgene, see Carbonyl chloride	...	... — ...
Phosphorus, red	lb.	1.40 — 1.50
Phosphorus, yellow	lb.	1.55 — 1.60
Potassium bichromate	lb.	.44 — .46
Potassium bromide granular	lb.	1.35 — 1.50
Potassium carbonate calcined, 85-90 per cent	lb.	.95 — 1.05
Potassium chlorate, crystals	lb.	.36 — .40
Potassium cyanide, 98-99 per cent	lb.	2.50 — 2.75
Potassium iodide	lb.	3.75 — 3.80
Potassium muriate 80-85 p. c. basis of 80 p. c.	ton	340.00 — 350.00
Potassium nitrate	lb.	.27 — .31
Potassium permanganate (U. S. P.)	lb.	4.00 — 4.10

Potassium prussiate, red	lb.	2.80 —	2.90
Potassium prussiate, yellow	lb.	1.22 —	1.25
Potassium sulphate, 90-95 p.c. basis 90 p.c.	ton	Nominal	
Rochelle salts	lb.	.39 —	.39½
Salammoniac, gray gran.	lb.	.15½—	.17
Salammoniac, white gran.	lb.	.15 —	.16
Sal soda	100 lb.	1.25 —	1.30
Salt cake	ton	25.00 —	26.00
Silver cyanide, based on market price of silver	oz.	.....	.....
Silver nitrate	oz.	.53¾—	.55
Soda ash, 58 per cent, light, flat	100 lb.	2.80 —	2.90
Soda ash, 58 per cent, dense, flat	100 lb.	3.60 —	4.00
Sodium acetate	lb.	.16½—	.17
Sodium bicarbonate, domestic	lb.	.02⅞—	.03
Sodium bicarbonate, English	lb.	.....	.....
Sodium bichromate	lb.	.23¾—	.24
Sodium bisulphite, powd.	lb.	.08 —	.10
Sodium chlorate	lb.	.22 —	.24
Sodium cyanide	lb.	.36 —	.40
Sodium fluoride, commercial	lb.	.17 —	.18
Sodium hyposulphite	lb.	.02½—	.....
Sodium molybdate, per lb. of Mo	lb.	2.50 —	.....
Sodium nitrate, 95%	100 lb.	4.50 —	4.60
Sodium nitrite	lb.	.35 —	.36
Sodium peroxide	lb.	.45 —	.50
Sodium phosphate	lb.	.03¾—	.04¼
Sodium prussiate, yellow	lb.	.38½—	.40
Sodium silicate, liquid (60 deg.)	lb.	.04½—	.05
Sodium sulphide, 30 per cent., crystals	lb.	.02¾—	.03
Sodium sulphide, 60 per cent., fused	lb.	.04¾—	.05
Sodium sulphite	lb.	.05 —	.06
Strontium nitrate	lb.	.25 —	.35
Sulphur chloride, drums	lb.	.06 —	.06½
Sulphur dioxide, liquid, in cylinders	lb.	.15 —	.40
Sulphur, flowers, sublimed	100 lb.	4.05 —	4.60
Sulphur, roll	100 lb.	3.70 —	3.85
Sulphur, crude	ton	Nominal	
Tin bichloride, 50 deg.	lb.	Nominal	
Tin oxide	lb.	.75 —	.90
Zinc carbonate	lb.	.25 —	.30
Zinc chloride	lb.	.13 —	.16
Zinc cyanide	lb.	Nominal	
Zinc dust, 350 mesh	lb.	.14 —	.16
Zinc oxide, American process XX	lb.	.14 —	.15
Zinc sulphate	lb.	.06 —	.07

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.35 —	.40
Benzol, 90 per cent	gal.	.....	.....
Toluol, pure water white	gal.	Nominal	
Xylol, pure, water white	gal.	.35 —	.50
Solvent naphtha, water white	gal.	.17 —	.22
Solvent naphtha, crude, heavy	gal.	.13 —	.16
Creosote oil, 25 per cent	gal.	.33 —	.35
Dip oil, 20 per cent	gal.	.29 —	.30
Pitch, various grades	ton	8.00 —	20.00
Carbolic acid, crude, 95-97 per cent	lb.	1.05 —	1.10
Carbolic acid, crude, 50 per cent	lb.	.60 —	.65
Carbolic acid, crude, 25 per cent	lb.	.35 —	.38
Cresol, U. S. P.	lb.	.18 —	.20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.00 —	1.25
Alpha naphthol, distilled	lb.	1.60 —	2.00
Alpha naphthylamine	lb.	.60 —	.62
Aniline oil, drums extra	lb.	.27 —	.28
Aniline salts	lb.	.32 —	.34
Anthracene, 80 per cent	lb.	.50 —	.65
Benzaldehyde (f.f.c.)	lb.	4.75 —	5.50
Benzidine, base	lb.	1.75 —	1.85
Benzidine, sulphate	lb.	1.40 —	1.50
Benzoic acid U. S. P.	lb.	5.25 —	5.50
Benzoate of Soda, U. S. P.	lb.	4.50 —	4.75
Benzyl chloride	lb.	2.25 —	2.50
Beta naphthol benzoate	lb.	10.00 —	12.00
Beta naphthol, sublimed	lb.	.85 —	.90
Beta naphthylamine, sublimed	lb.	2.65 —	.....
Dichlor benzol	lb.	.12 —	.18
Diethylaniline	lb.	4.00 —	5.00
Dinitro benzol	lb.	.35 —	.40
Dinitrochlorbenzol	lb.	.40 —	.42
Dinitronaphthaline	lb.	.55 —	.60
Dinitrotoluol	lb.	.55 —	.60
Dinitrophenol	lb.	.50 —	.55
Dimethylaniline	lb.	.63 —	.65
Diphenylamine	lb.	1.00 —	1.10
H-acid	lb.	2.25 —	2.50
Metaphenylenediamine	lb.	1.85 —	2.00
Monochlorbenzol	lb.	.19 —	.22
Naphthalene, flake	lb.	.10½—	.11
Naphthalene, balls	lb.	.12 —	.14
Naphthionic acid, crude	lb.	1.40 —	1.50
Naphthylamin-di-sulphonic acid	lb.	1.00 —	1.10
Nitro naphthaline	lb.	.45 —	.50
Nitro toluol	lb.	.50 —	.55
Ortho-amidophenol	lb.	.....	.....
Ortho-dichlor-benzol	lb.	.15 —	.18
Ortho-toluidine	lb.	1.25 —	1.30
Ortho-nitro-toluol	lb.	.75 —	1.00
Para-amidophenol, base	lb.	3.50 —	4.00
Para-amido-phenol, H. Cl.	lb.	4.00 —	5.00
Para-dichlor-benzol	lb.	.12 —	.15
Paranitraniline	lb.	1.25 —	1.30
Para-nitro-toluol	lb.	1.50 —	1.60
Paraphenylenediamine	lb.	3.00 —	3.50
Para toluidine	lb.	2.25 —	2.50
Phthalic acid anhydride	lb.	4.50 —	5.00
Phenol, U. S. P.	lb.	.53½—	.55
Resorcin, technical	lb.	6.00 —	7.00
Resorcin, pure	lb.	9.00 —	10.00
Salicylic acid	lb.	1.00 —	1.10
Salol	lb.	1.85 —	2.00
Sulphanilic acid, crude	lb.	.32 —	.35
Toludin	lb.	2.50 —	.....
Toluidine-mixture	lb.	.75 —	.85

Petroleum Oils

Crude (at the Wells)

Pennsylvania	bbl.	4.00 —	.....
Corning, Ohio	bbl.	2.85 —	.....
Somerset, Ky.	bbl.	2.60 —	.....
Wooster, Ohio	bbl.	2.38 —	.....
Indiana	bbl.	2.08 —	.....
Illinois	bbl.	2.22 —	.....
Oklahoma and Kansas	bbl.	2.00 —	.....
Caddo, La., light	bbl.	2.00 —	.....
Corsicana, Tex., light	bbl.	2.00 —	.....
California	bbl.	.98 —	1.32
Gulf Coast	bbl.	1.00 —	.....
Fuel Oil			
New York	gal.	.11 —	.....
Pittsburgh	gal.	.07½—	.10
Oklahoma-Kans.	bbl.	1.50 —	2.35
Texas	bbl.	1.50 —	1.90
Los Angeles	bbl.	1.52 —	.....
San Francisco	bbl.	1.45 —	.....
Gasoline (Wholesale)			
New York	gal.	.24 —	.....
Boston	gal.	.25 —	.....
Pittsburgh	gal.	.26 —	.....
Chicago	gal.	.21 —	.....
Oklahoma	gal.	.25 —	.....
San Francisco	gal.	.20 —	.....

Lubricants

Black, reduced, 29 gravity, 25-30 cold test	gal.	.21 —	.22
Cylinder, light	gal.	.36 —	.38
Cylinder, dark	gal.	.35 —	.36
Paraffine, high viscosity	gal.	.40 —	.41
Paraffine, 903 sp. gr.	gal.	.33 —	.34
Paraffine, .865 sp. gr.	gal.	.22 —	.23

Flotation Oils

(Prices at New York unless otherwise stated)

Pine oil, crude, f.o.b. Florida	gal.	.44 —	.....
Pine oil, steam distilled, sp. gr. 0.925-0.940	gal.	.53 —	.....
Pine oil, destructively distilled	gal.	.49 —	.53
Pine-tar oil, sp. gr., 1.025-1.035	gal.	.35 —	.....
Pine-tar oil, double refined, sp. gr. 0.965-0.990	gal.	.40 —	.....
Pine oil, light, sp. gr. 0.950, tank cars, f.o.b. works	gal.	.37 —	.....
Pine oil, heavy, sp. gr. 1.025, tank cars, f.o.b. works	gal.	.26 —	.....
Pine tar, thin, sp. gr. 1.060-1.080	gal.	.30 —	.....
Turpentine, crude, sp. gr. 0.930-1.000	gal.	.40 —	.....
Hardwood oil, f.o.b. Michigan, sp. gr. 0.960-0.990	gal.	.19 —	.....
Hardwood oil, f.o.b. Michigan, sp. gr. 1.00-1.08	gal.	.19 —	.....
Wood creosote, ref. f.o.b. Florida	gal.	.31 —	.....

Vegetable and Other Oils

China wood oil	lb.	.21 —	.22
Cottonseed oil, crude	lb.	.17½—	.18
Linseed oil, raw, cars	gal.	1.40 —	1.42
Peanut oil, crude	gal.	1.37 —	.....
Rosin oil, first run	gal.	.35 —	.....
Rosin oil, fourth run	gal.	.66 —	.....
Soya bean oil, Manchuria	lb.	.18¾—	.19
Turpentine, spirits	gal.	.45 —	.....

Miscellaneous Materials

Barytes, floated, white, foreign	ton	40.00 —	50.00
Barytes, floated, white, domestic	ton	30.00 —	36.00
Beeswax, white, pure	lb.	.58 —	.64
Casein	lb.	.22 —	.30
Chalk, light, precipitated, English	lb.	.....	.....
China clay, imported, lump	ton	17.50 —	36.00
China clay, domestic, lump	ton	12.50 —	20.00
Feldspar	ton	8.00 —	12.00
Fuller's earth, powdered	100 lb.	1.00 —	1.50
Ozokerite, crude, brown	lb.	.65 —	.75
Ozokerite, American, refined, white	lb.	.75 —	1.00
Red lead, dry, carloads	lb.	.10 —	.11¼
Rosin 280 lb.	bbl.	7.50 —	.....
Soapstone	ton	10.00 —	12.50
Talc, American, white	ton	15.00 —	22.00
White lead, dry	lb.	.09 —	.10

Refractories, Etc.

(F.O.B. Works)

Chrome brick	net ton	Nominal	
Chrome cement, Grecian	net ton	Nominal	
Clay brick, 1st quality fireclay	per 1000	50.00 —	55.00
Clay brick, second quality	per 1000	35.00 —	40.00
Magnesite, raw	ton	30.00 —	35.00
Magnesite, calcined	ton	35.00 —	36.00
Magnesite, Grecian, dead burned	net ton	85.00 —	90.00
Magnesia brick, Grecian, 9x4½x2½	net ton	135.00 —	140.00
Silica brick	per 1000	50.00 —	60.00

Ferroalloys

Ferrocarbontitanium, 15-18 per cent, carloads, f.o.b. Niagara Falls, N. Y.	ton	160.00 —	.....
Ferrocerium	lb.	18.00 —	.....
Ferrochromium, per lb. of Cr	lb.	.50 —	.....
Ferromanganese, domestic	ton	250.00 —	.....
Ferromanganese, English	ton	325.00 —	.....
Ferromolybdenum, per lb. of Mo	lb.	5.00 —	.....
Ferrosilicon, 75 per cent, f.o.b. N. Y.	ton	.....	.....
Ferrosilicon, 50 per cent, carloads, del., Pittsburgh	ton	170.00 —	195.00
Ferrosilicon, 50 per cent, contract	ton	100.00 —	175.00
Ferrotungsten, 75-85 per cent, f.o.b. Pittsburgh	lb.	2.30 —	2.35
Ferrouranium, f.o.b. works, per lb. of U	lb.	7.00 —	.....
Ferrovanadium, f.o.b. works	lb.	4.00 —	5.00

Ores and Semi-finished Products

Antimony ore, per unit		1.60 —	1.75
Chrome ore, 48 per cent minimum, f.o.b. Cal., per unit	ton	1.50 —	1.60
Chrome ore, 43 per cent and over, New York, per unit	ton	1.50	
Manganese ore, 48 per cent and over, per unit	ton	1.20	
Manganese ore, chemical	ton	80.00 —	100.00
Molybdenite, per lb. of Mo$_2$	lb.	2.10 —	2.15
Tungsten, Scheelite, per unit of WO$_3$	ton	20.00 —	24.00
Tungsten, Wolframite, per unit of WO$_3$	ton	20.00 —	24.00
Uranium oxide, 96%	lb.	3.25 —	3.60
Vanadium pentoxide, 99%	lb.	10.50 —	.....
Pyrites, foreign	unit	.17 —	.17½
Pyrites, domestic	unit	.28 —	.30

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

THE AMERICAN CEELULOZ & CHEMICAL MANUFACTURING COMPANY, Dover, Del. Capital, $25,000,000. To manufacture chemicals and celluloid products. Incorporators: Henry Bigham, New York; Frank C. Welles, New Rochelle; and O. R. Houston, Great Neck Station, N. Y.

THE ATLAS FOUNDRY COMPANY, Newark, N. J. Capital, $125,000. To operate a local plant for the production of iron and brass products.

THE AUDUBON PAPER STOCK COMPANY, Inc., New York. Capital, $10,000. To manufacture paper. Incorporators: Solomon Ash, A. E. Engeman, New York; and William H. Hitchcock, Jersey City, N. J.

THE BEHRE CHEMICAL WORKS, Madison, N. J. Capital, $50,000. To manufacture chemicals and allied products. Incorporators: James Benny, Burgess A. Cruden, and A. S. Doolan, 27 East Eighteenth Street, Bayonne.

THE BIG VEIN LEAD & ZINC COMPANY, Miami, Okla. Capital, $250,000. To mine for lead and zinc. Incorporators: W. A. Dotty, Miami; G. B. Crumbine and J. A. Utterback, Oklahoma City.

THE BLYTHE COTTON OIL COMPANY, Los Angeles, Cal. Capital, $125,000. To operate a plant for the production of cotton seed oil. Incorporators: R. H. McLarn, G. G. and J. V. Blard, A. C. Anderson and Howard Prowse, Los Angeles.

THE BRITISH-AMERICAN METALLURGICAL CORPORATION, New York. Capital, $5,000,000. To engage in the treatment of ores and the production of chemical products. Incorporators: A. W. Britton, S. B. Howard and G. V. Reilly, New York.

THE BURNET TEXAS GRAPHITE COMPANY, Burnet, Tex. Capital, $62,500. To mine for graphite. Incorporators: P. B. McCable, Burnet; W. B. Garrett, Austin; and C. J Price, Topeka, Kan.

THE CALIFORNIA COTTON OIL COMPANY, Los Angeles, Cal. Capital, $100,000. To operate a plant for the production of cotton seed oil. Incorporators: J. P. Conduit, L. F. Martin, Los Angeles; and T. W. McDevitt, Phoenix, Ariz.

THE CLAREMONT MARL PRODUCTS COMPANY. Claremont, Va. Capital, $250,000. To manufacture marl products for fertilizer use. Incorporators: H. J. Arrington, Claremont; and C. D. Gilliam, Richmond.

THE COLE CHEMICAL COMPANY, St. Louis, Mo. Capital, $200,000. To manufacture chemicals and allied products. B. L. Cole is the principal incorporator.

THE CONSOLIDATED ZINC & SMELTING COMPANY, Inc., New York. Capital, $3,000,000. To engage in the mining, milling and concentrating of lead and zinc ores, etc.

THE COOKS FALLS DYE WORKS, Inc., New York. Capital, $30,000. To manufacture dyestuffs, etc. Incorporators: W. and H. and A. Hine, Cedarhurst, Brooklyn.

THE CROTON COLOR & CHEMICAL COMPANY, Croton, New York. Capital, $150,000. To manufacture chemicals and dyestuffs, etc. Incorporators: H. P. Thrig, E. R. Voltmer and F. C. Schmitz, 31 Union Square.

THE DANIEL BOONE MINING COMPANY, Quapaw, Okla. Capital, $150,000. To mine for lead and zinc. Incorporators: C. H Birr, Muskogee; J. E. Jenkins, Springfield, Mo.; and A. Avery, Oronogo, Mo

THE JAMES F. DUFFY CORPORATION, Bronx, N. Y. Capital, $15,000. To manufacture chemicals and lubricant products. Incorporators: J. S. Michtom, H. G. Fenton and J. F. Duffy, 182 White Plains Avenue.

THE DUPLICO MANUFACTURING COMPANY, New Brunswick, N. J. Capital, $100,000. To manufacture carbon paper and kindred specialties. Incorporators: J. H. Helm, I. B. Glueckfield and George R. Morrison, New Brunswick.

THE ELECTRIC STEEL COMPANY OF AMERICA, Dover, Del. Capital, $4,000,000. To manufacture iron, steel and other metals.

THE EXPORT NITRO-PHOSPHO COMPANY, Newark, N. J. Capital, $120,000. To manufacture phosphates and other fertilizers Incorporators: George R. Swain, John I. Sipp and C. Jacobs, Newark.

THE F. & G. CHEMICAL WORKS, Brooklyn, N. Y. Capital, $5,000. To manufacture chemicals. Incorporators: D. Lenkowsky and M. J. and H. Lesser, 277 Pennsylvania Avenue, Brooklyn.

THE FEDERAL SOAP CORPORATION, New York. Capital, $30,000. To manufacture soap products. Incorporators: R. K. Dehler, A. H. Rees and C. W. Harlow, 150 Nassau Street.

THE FLORIDA GLASS COMPANY, Tampa, Fla. Capital, $250,000. To manufacture glass and glassware of various kinds. C. J. Earley, president; Paul T. Davis, secretary.

THE GOODYEAR MINING COMPANY, Winburne, Pa. Capital, $200,000. To engage in a general mining business. Robert H. Somerville is treasurer and principal incorporator.

THE GRAY INDUSTRIAL LABORATORIES, Elizabeth, N. J. Capital, $125,000. To engage in the treatment of chemicals and chemical products. Incorporators: Thomas T. Gray, Frank A. Urner and Frank B. Mason, all of Elizabeth.

HANSEN, OLSEN & COMPANY, New York. Capital, $20,000. To manufacture paints and varnishes, etc. Incorporators: H. J. Hansen, O. Olsen and W. Ferguson, 27 Cedar Street.

THE HEBRON ROLLER MILLS COMPANY, Hebron, N. D. Capital, $10,000. To operate a local rolling mill. Incorporators: Eugene Weigel, Fred Schwenkand V. Ungerecht.

THE HOWE RUBBER COMPANY, Los Angeles, Cal. Capital, $200,000. To manufacture rubber goods. Incorporators: E. A. Sattler, New Brunswick, N. J.; C. A. Mullen, San Francisco; and E. M Reighard, Los Angeles.

THE HUDSON FOUNDRY COMPANY, New York. Capital, $20,000. To operate a local foundry. Incorporators: J. C. Garrett and J. Mittleman, 27 William Street.

THE INDIA PRODUCTS COMPANY, New York. Capital, $30,000. To manufacture chemicals and allied products. Incorporators: E. F. and E. Groeniger and B Bernbaum, 320 Broadway, New York.

THE JOSIAH SMITH PHENYLE COMPANY, Inc., Yonkers, N. Y. Capital, $25,000. To manufacture paints, disinfectants, chemicals, etc. Incorporators: J. R. Roberson, F. M. Roberson and H. Raynes, 368 South Broadway, Yonkers.

THE LIBERTY MACHINE TOOL & DIE COMPANY, Newark, N. J. Capital, $80,000. To manufacture machine tools, dies, etc. Incorporators: Albert W. Wenzel, Charles L. Barrows, Newark; and H M. Bailey, Irvington.

THE LOWER KAHILTNA MINING COMPANY, Inc., New York. Capital, $250,000. To engage in mining and metallurgical operations. Incorporators: H. N. Armstrong, M. S. Mackay and H. Peters, 14 Wall Street, New York.

THE LYNCHBUEG GLASS WORKS, Lynchburg, Va. Capital, $300,000. To manufacture glass and glassware. Incorporators: N D. Eller, D. B. Ryland, Lynchburg.

THE MINERAL RIDGE MANGANESE CORPORATION, Strasburg, Va. Capital, $250,000. To mine for manganese. Incorporators: William B. Shaffer, Nazareth, Pa., and Charles F. Nelson, Strasburg.

THE NATIONAL ANODE COMPANY, Passaic, N. J. Capital, $100,000. To engage in the production of copper castings. Incorporators: Albert R. Bray, G. W. Bray and William F. Rothlisberger, Newark.

THE NUTRO-PEYO CORPORATION, New York. Capital, $50,000. To manufacture chemical prenarations, etc. Incorporators: L. and J. Rueff-Jordan and L. Bughee, 447 Fort Washington Avenue.

THE ORES CONCENTRATION COMPANY, Jersey City, N. J. Capital, $20,000. To engage in the concentration of ores. Incorporators: Ernest S. Hirschberg, Arthur L. Woodland and Paul F. Hauser, Jersey City.

THE PRESTON TRADING COMPANY, Inc., New York. Capital, $50,000. To manufacture paper and wood pulp. Incorporators: H. E. Herman, A. O. Ernst and G. G. Newhouse, 170 West Seventy-fourth Street.

THE REILLY-EDWARD COMPANY, Dover, Del. Capital, $25,000. To manufacture fertilizers. Incorporators: Frank S. Reilly, Baltimore, Md.; and W. T. Edwards, Readville, Va.

THE REPUBLIC OIL & SULPHUR COMPANY, New York. Capital, $2,000,000. To engage in the production of oil, gas, sulphur, etc. Incorporators: R. Eichman and Louis E. Jump, New York.

THE E. N. ROWELL COMPANY, Inc., Batavia, N. Y. Capital, $25,000. To manufacture paper, etc. Incorporators: E. N. Rowell, C. H. Ruprecht, Batavia, and E. G Buell, 368 Broadway, N. Y.

THE SERB PRODUCTS CORPORATION, Wilmington, Del. Capital, $100,000. To manufacture chemicals and sanctuary oils, etc. Incorporators: M. M. Clancy, C. L. Rimlinger and F. A. Armstrong.

THE SHELBY CHEMICAL COMPANY, Dover, Del. Capital, $250,000. To manufacture charcoal and acetate of lime. Incorporators: M. L. Rogers, L. A. Irwin and William G. Singer, Wilmington.

THE SOUTHERN CHEMICAL COMPANY, El Paso, Tex. Capital, $20,000. To engage in the production of saline products. David Russek is the principal incorporator.

STEIN, HALL & COMPANY, New York. Capital, $2,000,000. To manufacture chemicals. Incorporators: W. S. Goldfrank, W. E. Mann and J. C. Guggenheimer, 27 William Street.

THE STIEGLITZ-TRIEBER COMPANY, New York. Capital, $700,000. To engage in the refining and smelting of metals. Incorporators: F. J. Trieber, L. and A. Stieglitz, 228 Pearl Street.

THE UNION CHEMICAL GLASSWARE COMPANY, Bronx, N. Y. Capital, $20,000. To manufacture chemical glassware. Incorporators: J. S. Einshon, D. Buegeleisen and A. L. P. Pollack, 601 West 168th Street.

THE UNITED LEAD & ZINC COMPANY, Oklahoma City, Okla. Capital, $50,000. To mine for lead and zinc. Incorporators: L. B. Grant, R. B. Halliburton and W. C. Brissey.

THE WILLIAMS CHEMICAL CORPORATION, Dover, Del. Capital, $10,000,000. To manufacture chemicals and allied products. Incorporators: William A. Rogers, Philip L. Nieser and Joseph F. Curtin, all of New York.

THE WILLIAM WATERALL & COMPANY, Camden, N. J. Capital, $125,000. To manufacture paints, white lead, etc. Incorporators: Samuel A. Matlack, Thomas G. Hawke and Ernest W. Holdt.

Construction and Operation

Alabama

ASHLAND.—The Sutton Steele & Steele Manufacturing Milling & Mining Company has completed its organization plans, and will install new dry process with dedusting, classifying and concentrating machinery in its plant to have an output of approximately 50 tons of lead and zinc every ten hours. Hugh B. Evans is president and manager.

ASHLAND.—The Graphite Mills, which recently increased their capital from $80,000 to $250,000, is now developing 80 acres of graphite properties, having a capacity of about 200 tons per ten hours. The company has entirely completed the installation of crushing, classifying and concentrating machinery at a cost of about $60,000.

GADSDEN.—G. W. Heber and N. H Sewall are considering plans for the development of about 400 acres of manganese property located four miles from Ivalee.

LINEVILLE.—The Liberty Graphite Company has recently completed the installation of new machinery in its plant to provide for an increase in its capacity to about 150 tons daily. Leo K. Steiner is president.

TRUSSVILLE.—The Birmingham-Trussville Iron Company has completed extensive improvements at its furnace, and is planning to inaugurate operations at an early date.

Arizona

KINGMAN.—The Standard Mineral Company is planning for the early construction of a new 100-ton mill at its property to provide for increased capacity. The company will soon commence on extensive development work, and arrangements have been made for the installation of a large quan-

tity of new machinery, including gas engines, compressors, pumps and machine drills.

KINGMAN.—Walter H. Brown and associates are planning for the immediate construction of a new milling plant on the Golconda Extension.

KINGMAN.—Sitton & Murphy are planning for the immediate development of the old Shipp mine in the Aquarius mountains. This mine was formerly famous as a silver producer, and it is held that the vein is rich in copper.

Arkansas

WARREN.—Fire, on Feb. 26, partially destroyed the plant of the Warren Cotton Oil & Manufacturing Company, with total loss estimated at $125,000. It is said the plant will be immediately rebuilt.

FORT SMITH.—Announcement has been made of the merger of the Ozark Refining Company and the Prospect Oil & Gas Company, to be capitalized at $1,500,000, and known as the Ozark Oil & Refining Company. The new company is planning for extensive development work in the Humboldt, Kan., field, and eight new wells will be sunk as soon as the weather conditions permit. Extensive improvements will be made at the plant of the Ozark Refining Company, including the installation of new machinery to increase the capacity from 300 to 600 barrels, to be increased ultimately to 1500 barrels, the latter work being estimated to cost $40,000.

California

LOS ANGELES.—The American Dye Works, corner Washington Street and Griffith Avenue, has had plans prepared for the construction of a new shop building, about 20 x 100 ft., at 810 East Washington Street.

LOS ANGELES.—The California-Burdett Oxygen Company, Vernon, near Los Angeles, has completed the construction of extensive additions to its plant for the production of oxyacetylene gas.

LOS ANGELES.—The American Cement Products Company, 2348 Long Beach Avenue, manufacturer of steel reinforced-concrete specialties, is planning to equip a section of its plant for the manufacture of pipe, fence posts and kindred products. E. B. Blinn is president.

PILLMORE.—The Ventura Refining Company has completed the construction of a new local plant for the extraction of wax from its lubricating stock. The new plant will be operated as a by-product works.

ETNA.—I. J. Luce of Seattle, Wash., and John M. Tetherow of Grant's Pass, Ore., who recently acquired the Blue Jene gold mine near Etna operated by the Siskiyou Syndicate, have commenced the construction of a large new stamp-mill, and are planning for extensive developments in the property.

MONTEZUMA.—J. C. Heald has commenced alterations and improvements in his mill in the Nashville district, to provide for increased capacity, and it is anticipated that the work will be completed at an early date.

PILOT HILL.—Extensive improvements are being made at the mill which formerly operated on gold ore from the Buzzard mine. New concentrators are also being provided for the treatment of chrome ore from the Pilot Hill and Salmon Falls districts. It is expected that the work will be completed and operation inaugurated at an early date.

BEAUREGARDE.—Plans have been completed for the construction of a large new 150-ton mill at the group of tungsten claims on Pine Creek in the White Mountains, which were recently taken over by new interests. It is also planned to construct a new electric power line. Cooper Shapley is manager.

Colorado

ELDORA.—Rapid progress is being made in the construction of a large new mill at the Huron gold mine, and it is expected that the work will be completed in the near future.

CLIMAX.—The Climax Molybdenum Company is rushing to completion the construction of its new 250-ton mill for the handling of its molybdenum. The company has also made arrangements for housing 185 of its employees. It is a subsidiary of the American Metal Company. J. M. White is manager.

BLACKHAWK.—Robert Wilkinson and associates have completed the organization of the Powers Mining, Milling & Leasing Company, and taken over the Powers mine in the Russell district. The new company is planning for the installation of new machinery, including electric pumps, air-compressors, etc., at the mine, which is said to be one of the best copper producers in Gilpin County.

BRECKENRIDGE.—Plans are under consideration for the construction of a new mill at the Royal Tiger mine. T. A. Brown is superintendent.

CLIMAX.—The Pingrey Mines Company has commenced extensive development of its molybdenum properties in the Black Metal group of claims on the Bartlett Mountain, and plans are now being completed for the construction of a new 500-ton concentration plant. O. A. King is manager.

Delaware

WILMINGTON.—The nineteen-inch mill at the local plant of the Midvale Steel Company was recently severely damaged, with total loss estimated at $75,000. It is said the destroyed plant will be immediately rebuilt.

WILMINGTON.—The Sugar Refining Company is having preliminary plans prepared for the erection of a large new sugar refinery and power house on the Delaware River. The entire project is estimated to cost about $10,000,000.

Florida

TAMPA.—W. M. Brooks, Tampa, and J. B. Porter, Buffalo, N. Y., have recently acquired extensive phosphate properties near Tampa, and are planning for the immediate installation of a large mining plant for development.

Georgia

SAVANNAH.—The Savannah Warehouse & Compress Company is planning for extensive additions to its high-density cotton compress plant, to provide for increased capacity, the entire work being estimated to cost about $200,000. Col. G. Arthur Gordon is president.

Idaho

SAGLE.—The Armstead Mines Company is considering plans for the construction of a large new mill at its properties in Bonner County during the coming spring. H. H. Armstead is president.

Illinois

CHICAGO.—The Standard Steel Castings Company is making rapid progress in the construction of a new one-story plant at Clearing, Ill. The structure will be about 100 x 200 ft., and is estimated to cost $100,000.

CHICAGO.—The American Cocoanut Butter Company, 2531 West Eighteenth Street, has commenced the erection of a new five-story refinery and power house, about 61 x 80 ft., at 2822-26 South Kilbourne Avenue. The new plant is estimated to cost about $60,000.

CHICAGO.—Work has been commenced by the Union Special Machine Company, West Kinzie Street, on the construction of a new three-story and basement plant, about 100 x 100 ft., at 300-14 West Kinzie Street to cost $250,000. The George A. Fuller Company, 140 South Dearborn Street, has the contract for erection.

CHICAGO.—The American Clay Machinery Company is building a new one and two-story plant at Mansfield, Ohio. The structure will be about 120 x 300 ft., and will cost $80,000. The H. A. Peters Company, 19 South La Salle Street, is the contractor.

LOCKPORT.—The Coke Products Manufacturing Company is making rapid progress in the construction of a large new mill for the manufacture of coke products.

Indiana

INDIANAPOLIS.—The Parker Tire & Rubber Company, Merchants' Bank Building, is considering the construction of a new one-story brick, steel and concrete factory building, about 100 x 400 ft., at South Eastern Avenue and Belt Railway.

INDIANAPOLIS.—The plant of the Stenotype Company is being operated to capacity for the manufacture of fuse parts for the government, order for which has recently been received.

MONTEREY.—The Monterey Electric Light & Power Company, recently incorporated with a capital of $60,000, has had plans prepared for the construction of a new one-story electric power plant, about 50 x 125 ft., to cost $50,000.

Kentucky

CLOVERPORT.—Fire recently destroyed a section of the plant of the Standard Oil Company including two tanks containing about 17,000 gal. of gasoline and oil.

Maryland

BALTIMORE.—The Bethlehem Steel Company has made announcement that plans are under consideration for extensions and additions at its Sparrows Point plant.

BALTIMORE.—The Maryland Bolt Works will build a new addition to its plant to provide for increased capacity.

BALTIMORE.—Plans have been filed by the Federal Tin Company, East Barre Street, for the construction of additions to its plant to provide for increased capacity. Contract for erection has been awarded.

EDGEWOOD.—The United States Government has made announcement that approximately 1000 acres of land adjoining the Aberdeen proving grounds have been acquired for the erection of a large new plant to be devoted to the production of poisonous gases.

HAGERSTOWN.—The Western Maryland Railroad Company has awarded a contract for the erection of a new wheel-shop at its local plant.

ANNAPOLIS.—The State Agricultural Line Board is planning for the acquirement of a site now under consideration to provide for the construction of a new limestone crushing plant.

Massachusetts

BOSTON.—Knox & Morse Company, 96 High Street, has recently awarded a contract to Edward B. Smith, Auburn Street Waltham, for the erection of a new chemical shop at 41 Everett Street, Allston, to be one-story, of brick construction.

WORCESTER.—The Peter Wood Dyeing Company has recently taken over the plant and property of the Thibert Manufacturing Company, Millbury, and will use as an extension to its present plant.

Minnesota

MINNEAPOLIS.—The Gas Traction Foundry Company, 2907 Southeast Fourth Street, has recently had plans prepared for the construction of a new one-story addition, about 100 x 300 ft., to its foundry, to cost $70,000. W. L. Alban, Endicott Building, St. Paul, is architect.

STILLWATER.—The Twin City Forge & Foundry Company has recently filed plans for the construction of a new foundry, about 125 x 400 ft., to cost $50,000. Contract for erection has been awarded.

Missouri

ST. LOUIS.—The Kardell Tractor & Truck Company is said to be considering the construction of a new plant at Oldsmar, Fla., for the manufacture of tractors and similar products.

ST. LOUIS.—The Bridge & Beach Manufacturing Company, manufacturer of stoves, ranges, etc., has recently acquired a tract of ten acres at the northeast corner of the intersection of the Belt Line and Union Avenue, as a site for the construction of a new plant.

KANSAS CITY.—The Witte Engine Works, Sixteenth Street, manufacturer of gas engines, etc., will build a new one-story addition to its plant to provide for increased capacity. The structure is estimated to cost $10,000. Contract for erection has been awarded.

SAGINAW.—The Griffith Lead & Zinc Company is planning for extensive development work on its 750-acre tract recently leased from the Saginaw Mining & Leasing Company. Plans are also under consideration for the construction of a new 350-ton concentration plant.

WENTWORTH.—The Wentworth Lead & Zinc Company, recently incorporated with a capital stock of $200,000, has completed its organization plans, and will develop about 40 acres of lead and zinc properties. A new 250-ton mill will be constructed. D. C. Morris is president.

Montana

GREAT FALLS.—The Anaconda Company is considering plans for immediate construction work on a large new plant at its Boston and Montana works, to be devoted to the electrolytic production of ferromanganese, which is essential in the manufacture of steel.

Nevada

YERINGTON.—The Bluestone Mining & Smelting Company is rushing to completion the construction of a large new plant at its local properties, including two 8-ft. Hardinge ball-mills and flotation apparatus, and it is expected that operations will be inaugurated within the next few weeks.

New Jersey

JERSEY CITY.—Fire, on March 2, damaged the plant of the Crew Levick Company, Ravine Road and West Shore Railroad, to the extent of about $10,000.

OLD BRIDGE.—Due to the acute shortage of coal, the Brookfield Glass Company has been compelled to suspend operations until permanent relief is in sight.

HARRISON.—The National Oil Products Company, Essex Street, has awarded a contract for alterations and improvements in its plant to cost about $63,000. The Becker Construction Company, 361 Grove Street, Newark, is the contractor.

RAHWAY.—Fire, on March 4, partially destroyed the plant of the Rahway Chemical Company, Broad Street and Maple Avenue, with total loss estimated at $15,000. Irwin S. Joseph is president.

BUTLER.—A portion of the plant of the Gulf Oil Refining Company was destroyed by fire on Feb. 21, including four tanks containing about 30,000 gal. of oil.

DELAWANNA.—The Worthen & Aldrich Company, operating a large local dye works, will build a new addition to its plant, about 80 x 160 ft., to cost about $250,000. Plans for the structure have been prepared.

PAULSBORO.—Fire, on Feb. 21, destroyed the hexite catalytic house at the Repauno plant of the E. I. du Pont de Nemours Company at Gibbstown, with total loss estimated at about $50,000. It is said the destroyed structure will be immediately rebuilt.

DELANCO.—The Consolidated Paper Tube Company, Philadelphia, Pa., is having plans prepared for the construction of a new two-story and basement brick local plant, about 50 x 80 ft.

New York

NEW YORK.—The American Chemical Products Company, a Delaware incorporation, has filed authorization papers to operate in New York. G. B. McLeod, 23 Liberty Street, is local representative.

GLENDALE, LONG ISLAND.—The James A. McCafferty & Sons Manufacturing Company, 506 Driggs Avenue, Brooklyn, has had plans prepared for the construction of a new one-story metal works addition to its paint manufacturing plant. The structure will be about 30 x 58 ft.

LONG ISLAND CITY.—The Van Iderstine Company is having plans prepared for the erection of a new addition to its tallow manufacturing plant at Newtown Creek. Edward Hahn, Bridge Plaza, Long Island City, is architect.

MARINERS' HARBOR, STATEN ISLAND.—The Proctor & Gamble Manufacturing Company, Cincinnati, Ohio, has had plans prepared for the construction of six new factory buildings at its plant at Port Ivory, to provide for increased capacity. The Ferro-Concrete Construction Company, Richmond and Harriet Streets, Cincinnati, has the contract for erection.

CORTLAND.—The Cortland Specialty Company, manufacturer of chemicals, etc., is having preliminary plans prepared for the reconstruction of the section of its one and two-story plant, about 67 x 177 ft., recently destroyed by fire. C. W. Clark, 9 Charles Street, Cortland, is architect.

TROY.—Operations have been discontinued at the Breaker Island plant of the American Steel & Wire Company, near Troy, and it is said that the property will be sold. The site consists of about 100 acres, adjacent to the tracks of the New York Central Railroad.

FULTON.—The Oswego Falls Pulp & Paper Company, 314 South First Street, has had plans prepared for the erection of a new two-story addition, to provide for increased capacity. The structure is estimated to cost about $20,000.

Ohio

CINCINNATI.—The Newport Rolling Mill Company has acquired property near Lowell Street, and will use it as a site for the construction of a new addition to its plant. J. B. Andrews is president.

CINCINNATI.—The Cincinnati Pulley Machinery Company has taken out a building permit for the erection of a new addition to its plant on East Third Street, to cost about $6,000.

CLEVELAND.—Fire recently partially destroyed the foundry of the Federal Metal Company, 6621 Morgan Avenue, with loss estimated at $20,000.

CLEVELAND.—The Variety Iron & Steel Works has acquired property, about 130 x 156 ft. on Hamilton Avenue, Northeast, near East Thirty-third Street, and is said to be considering the erection of new additions to its plant.

CLEVELAND.—A building permit has been taken out by the American Steel & Wire Company for the construction of a new benzol plant, about 95 x 110 ft., and a new storage plant, 42 x 146 ft., at Campbell Road, Southeast, and the Ohio Canal, to cost $57,000 and $15,000, respectively.

FINDLAY.—The Buckeye Traction Company is having plans prepared for the construction of a new factory building, and will immediately install a new electric converting furnace to be used for steel production. The plant is estimated to cost $50,000.

HAMILTON.—Contract has been awarded by the Hamilton Furnace Company for extensive improvements and additions to its plant in Cokeotto, near Hamilton, including the construction of an ore bridge and car dumper, the entire work to cost about $500,000. Hunkin & Conkey, Cleveland, are the contractors.

LIMA.—The Monarch Machine Company has awarded a contract to the Concrete Steel Construction Company, Lima, for the erection of a new one-story steel and concrete addition to its plant, about 80 x 200 ft.

TOLEDO.—The F. L. Royster Guano Company has acquired seven acres of land on the north side of the Michigan Central Railroad, near the Toledo Disposal plant, and has awarded contracts for the construction of a large new fertilizer works, the main building of which will be 180 x 500 ft., of brick and cement construction. The plant will have a capacity of about 150,000 tons of fertilizer per year, and about 200 hands will be employed for initial operations.

YOUNGSTOWN.—The Liberty Steel Company is making rapid progress in the construction of its new plant near Warren, to be used for the production of tin. The plant comprises three large mill buildings with tin stacks, administration building and auxiliary structures. It is expected that the new plant will be completed and ready for operation by April 1.

Oklahoma

PICHER.—The Bendene Mining Company is considering plans for the construction of a new concentration plant at its lead and zinc properties.

MIAMI.—J. E. Hellams, 217 South Seventh Street, Muskogee, and associates, are planning for the organization of a new company to be capitalized at $100,000 for the purpose of developing lead and zinc properties in the Miami field. A concentration plant is also planned.

QUAPAW.—The Quapaw Mining Company has plans under consideration for the construction of a new mill on its 80-acre lease, near the Lincolnville station, south of Quapaw.

QUAPAW.—The Medical Mining Company is planning for the immediate construction of a new 250-ton mill at its properties west of Quapaw.

Oregon

GRANTS PASS.—W. A. Sharp, Grant's Pass, and L. C. Sharp, Plattsmouth, Neb., have acquired the placer mining property of the Hydraulic Mining Company, Upper Jump-off-Joe Creek, Jackson County. Extensive improvements will be made on the property, including the installation of hydroelectric precipitating value-recovering machinery.

Pennsylvania

BERWYN.—The American Bronze Company has had plans prepared for the construction of a large new foundry building at its plant.

MARCUS HOOK.—The Sun Oil Company has taken bids for the erection of a new two-story brick administration building, about 35 x 47 ft., at its plant.

PHILADELPHIA.—The Tacony Steel Company has recently acquired property at Bleigh and Spring Streets, and Bleigh and Eugene Streets, for a consideration said to be $65,000, and is considering the construction of additions to its plant on the sites.

PHILADELPHIA.—The Pecora Paint Company, Fourth and Sedgley Streets, has acquired the two and three-story factory buildings, at Sedgley and North Penn Railroad, for a consideration of $100,000, to be used as a new manufacturing plant.

PHILADELPHIA.—The E. I. du Pont de Nemours Company has formally taken over the plant of Harrison's, Inc., manufacturer of paints and chemicals, at Thirty-fourth Street and Gray's Ferry Road, by the recording of the necessary deed.

PITTSBURGH.—Officials of the Pittsburgh Testing Laboratory, one of the best known institutions of its kind in the country, have turned over to the United States Government, for the duration of the war, the entire five-story plant, with full equipment of chemical, physical and analytical laboratories, scientific instruments, laboratories for testing cement and apparatus for inspecting and testing steel. George H. Clapp is president.

Rhode Island

PROVIDENCE.—The Nicholson File Company, Acorn Street, has commenced the construction of three new additions to its plant on Kinsley Avenue.

Tennessee

CENTERVILLE.—The Tennessee-Illinois Phosphate Company, recently incorporated with a capital of $200,000, has acquired about 300 acres of land and is planning for the construction of a plant for mining, milling and refining phosphate.

KNOXVILLE.—The Tennessee Manganese Company has filed notice of an increase in its capital from $20,000 to $200,000, to provide for extensive improvements in its mining facilities, and the construction of a new electric steel furnace to cost about $100,000. The new furnace will have a capacity of 25 tons of manganese daily for initial operations.

MEMPHIS.—Fire, on February 26, damaged the plant of the Webster-Warnock Chemical Company, Union Street, to the extent of $25,000.

Texas

GREENVILLE.—The North Texas Oil & Refining Company is planning for the immediate construction of a large refinery on a site at the junction of the Mineola branch of the M. K. Railway with the Texas Midland Railway, to cost about $250,000. The plant will have a daily capacity of 5000 barrels.

Utah

EUREKA.—Plans are under way for the organization of a company to be known as the Majestic Copper Mining Company, with capitalization of $1,000,000, for the development of a large tract of land in the Erickson district, west of Eureka. Harry Webber, Jr., New York, is interested in the company.

Virginia

NORFOLK.—The Norfolk Glass Manufacturing Company, recently incorporated with a capital of $250,000, has acquired ten acres of land near the junction of the Norfolk Southern and the Virginia Railways, and is planning for the immediate construction of a large plant for the manufacture of glass and glassware. About 300 hands will be employed.

Wisconsin

PLATTEVILLE.—Fire at the plant of the White Rose mine, one of the Gus E. Brown properties, entailed a loss of about $15,000. The destroyed section will be immediately rebuilt.

PLATTEVILLE.—The Wisconsin Zinc Company has completed the construction of a new 500-ton mining and milling plant at its Copeland mine in the Shullsburg district.

MILWAUKEE.—The Milwaukee Paper Box Company, 400 Florida Street, has had plans prepared for the erection of a new five-story and basement factory, about 100 x 150 feet, at South Pierce Street and Muskegon Avenue. The estimated cost of the structure is $150,000.

HALIFAX.—The plant of the Martin Sembur Paint Company was recently partially destroyed by fire, with total loss estimated at $70,000.

Unwavering Purpose

THERE comes a time in every fight for principle when the critical factor for victory is steadfastness of purpose, a clear vision of the goal, and a determination to win. This is particularly true if the enemy for the time being is apparently victorious and defeat stares us in the face. Then if ever is the time to tighten the grip and determine to fight to the finish.

Let us have no delusions about the war—our war. Germany is winning it to-day, has been winning it for some time past; not always by force of arms, but often by the poison of subtle propaganda. We have only begun to play our part, and the peak of our participation cannot come for another year or more. In the meantime many demands are going to be made on us, one of which is to translate patriotism into dollars and make a success of our Liberty Loans. There must be no wavering, no question of success. If the United States is to come out of this war more than an economic vassal of her enemy; if the chemical and metallurgical industries of this country are to endure; if we are to hold what we have gained and protect what we have already given, then there is naught for us to do but respond to every call. We haven't yet begun to sacrifice in this country; we have yet to earn that glory.

Our supplement to this issue typifies the spirit of unity we would engender in our people—a spirit that will say with Lincoln, "We accepted this war for a just and worthy object and the war will end when that object is attained. Under God, I hope it will not end until that time."

The Need for Chemical Statistics

FOR some time past the conviction has been growing that a beginning should be made toward the gathering and publication of vital statistics in the chemical industry. As nearly as we can ascertain, there is a feeling that our chemical industry has become established on a fairly firm foundation; that the war has lasted long enough to insure a degree of permanence that would have been impossible if Germany had achieved her ends by a swift stroke; and finally that the longer the war lasts the more certain will be our chemical independence. If these things are true—and we believe they are—we should have better facilities for exact knowledge of the industry. Specifically we should have organized sources of information as to imports, exports, raw materials, finished products, production and consumption. These data are a necessary guide to logical and sound development in the industry.

We believe that the work should be undertaken by the cooperation of established government agencies. Since many of the raw materials of chemical manufac-

ture are of a mineral nature, and inasmuch as the United States Geological Survey has already extended the scope of "Mineral Resources of the United States" to include potash, sulphuric acid, cement, phosphate, etc., we suggest that a beginning be made here and that the work be elaborated. It would be of incalculable value at this stage of our growth to have chemical statistics and data comparable to those which the mineral industry enjoys. If the Survey is not the agency for this work, the Bureau of Mines may be.

Happily a beginning has been made toward a knowledge of our chemical imports. Dr. E. R. Pickerell, chemist in charge of the United States Appraiser's Laboratory, New York, is gathering data for the year prior to the war, June 1, 1913 to June 30, 1914. The completed work will show what competition we will have to meet and what essentials we will have to produce. This should be continued as an annual report and extended to cover exports as well. Such data combined with the domestic statistics previously suggested will fortify the chemical industry immeasurably. In established government agencies like the Bureau of Foreign and Domestic Commerce, the Geological Survey and the Bureau of Mines we have the machinery to make a quick start toward exact knowledge of the chemical industry.

Electric Furnaces for Zinc Melting

WE HAVE always held and often expressed a faith in the rôle of the electric furnace in the metallurgy of zinc. Proponents of the retort furnace are still prone to lift their eyebrows skeptically whenever electric-furnace spelter is mentioned; but the most partisan of these adherents must have seen a great light in the sudden perfecting of as difficult and elusive a process—zinc from electrolytic tanks. The economic reduction of zinc oxide by electrothermal methods is as well established as the reduction of zinc sulphate by electrochemical, and he would be stubbornly foolish to maintain that the remaining problem of economic condensation is unsolvable.

However, the electric furnace will undoubtedly come into its own as a melter of zinc metal and alloys before its common adoption for reduction purposes. Electric brass-melting is in its infancy, but even so the installation of the first furnace has been generally followed by additional units. Naturally some failures have resulted in trying to adapt the furnace to its duty: as an extreme instance, an arc furnace for melting zinc would be as useful as a bull jig for slime concentration. Brief consideration of the problem of melting a fusible, volatile and combustible metal seems to indicate the need of a moderate furnace temperature, preferably with heat applied below the bath and a closed laboratory containing an atmosphere controlled as to composition and pressure. These ideals involve structural complications which may be impossible to attain fully in large-capacity furnaces, even though it may now be possible to build and operate small induction furnaces under such conditions. Large furnaces reverberating heat down into the bath from resistors placed alongside fulfill most of the requirements, however, and are operating quite satisfactorily to-day.

The days of the older pot-practice of forming alloys in melting holes seem to be numbered by the growth of foundries producing large tonnages of uniform metal. How long would an electrolytic copper or zinc refinery, for instance, tolerate the melting of a hundred tons of cathodes daily in pot-charges of 200 pounds? The rising cost and decreasing quality of the crucibles, the excessively low thermal efficiency of the fuel used, the huge furnace building and quantities of skilled labor required, alike exclude this practice from a modern metallurgical plant. This whole question has been fought over in the similar problem of the manufacture of tool steel—crucible steel. In both instances the sole justification of crucible practice has been "quality," and the electric furnace has beaten the crucible at its own game!

Tariff Philosophy

NOBODY who is informed can claim that we have ever had a wise, just and equitable tariff bill framed, as a whole, into law. We lacked the tools, the necessary instruments, to make it. We had only congressional committees composed mainly of lawyers; and lawyers, while of necessity a part of the order of life in civilization, are not the creators of civilization. Lawyers are finishers rather than producers.

Now we have an able Tariff Commission to collect and arrange information, but not to legislate, and the play of psychology in legislation is something we must consider. In other words, we must consider beforehand how Congress will feel when it has a tariff act to vote upon. Under our present laws, in regard to certain industries, there are loopholes through which foreign manufacturers can creep with their products and disorganize American industry by sheer astuteness, without even employing deceit. They can do this within the law. An easy way to avoid this danger is to stop up the loopholes by raising the tariff imposts. The real way is to go over the laws in good faith and with honest and frank examination of their provisions in detail.

The trouble with the mere process of just boosting the duties is that it raises the cost of things, and when the cost of things goes up public opinion comes down upon it. When public opinion is unfavorable to an increase in tariff rates Congress will not increase them. It makes no difference what the facts are, or where wisdom lies; Congress reflects public opinion, and public opinion is a contagious emotion. Now, emotion is not thoughtful.

It stands to reason, then, that if associations of manufacturers confine themselves to "helping" the Tariff Commission by pointing out only where higher duties are needed, the voice of public opinion, speaking of these persistent efforts, will be to the effect that manufacturers are the same yesterday, to-day, and forever, and that, like cherubim and seraphim, they continually do cry the song that was indicated by the chorus of manufacturers in the Chemical Grand Opera:

"Protection, Protection, we surely need some more;
We need it now and all the time; we've needed it before.
We chant our old Protection Hymn—it shows the easy way
To bring about Prosperity and let us Make some Hay."

And when public opinion concludes that manufacturers are presenting their claims with minds single to their own interests, and without consideration of the public welfare, like a lawyer trying a case at court who leaves all unfavorable evidence to be developed by opposing counsel, public opinion will close its mind to their appeal, and manufacturers will have no standing at its court, which is the Congress.

The Tariff Committees of Manufacturers' Associations are likely to fail in their efforts if they conceive their duties in the restricted sense of a lawyer at court. They must conceive their duties rather in the manner of a judge advocate at a court martial, looking for the truth and the general welfare rather than to how much they can get. They should not only give the impression of being fair, but be fair. If they appear before the Tariff Commission they should go with all the evidence instead of only that which favors them, and for every advance they ask they should offer a reduction if possible. Every product that can be made here with reasonable profit in world competition, without duty and without reduction in wages, should be made duty-free. It is the business of the Tariff Commission to discover these things and tell them to Congress; so why should not manufacturers tell them to the commission and aid in the reduction of unnecessary duties so that the tariff wall does not grow up too high? This it has often done in the past, only to fall down again like the walls of Jericho at the blast of public opinion, to the confusion and misery of all.

Public opinion in this country is neither docile nor obedient, as it is in Germany. It is subject also to the sinister influence of yellow newspapers which live by loud noise, and the loudest noise can be made in protest. Constructive thought is not noisy, and therefore it is unavailable to the yellow press. On the other hand, public opinion has a mind to fairness, and if manufacturers show themselves fair and in favor of a fair tariff they will stand a better chance than ever before of getting a fair deal. No one should ask for pork, which in politics means something for nothing, or wage without service. The ear of the public mind is sensitive to the cry for pork, and the response is usually violent—violent and destructive.

A Poor Pig-Iron Showing

THE only favorable reflection that can be made upon the record of pig-iron production in 1917 is that at the end of the year the Government took over the railroads with the intention of getting better service out of them, chiefly by doing things which the Government had not permitted the railroads themselves to do. The year's pig-iron production, as now officially reported, was 38,647,397 gross tons, against 39,434,797 tons in 1916, the record year. The decrease of 2.0 per cent is to be considered in connection with the fact that new blast-furnaces, averaging at least 150,000 tons' annual capacity per stack, were blown in as follows: In 1916, one each in May, June, November and December; in 1917, one in the first quarter, five in the second quarter, eight in the third quarter. The eighteen stacks have a capacity of about 3,000,000 tons a year, and considering the times at which they were blown in it is evident they contributed scarcely anything to the 1916 output, whereas the old furnaces and new furnaces combined should have been able to make between 41,000,000 and 41,500,000 tons in 1917.

The deficiency of nearly 3,000,000 tons in the 1917 production was due entirely to an insufficient supply of coke. That arose almost wholly from the railroads being unable to haul coal to by-product coke ovens and coke from beehive ovens to furnaces. The shortage in the movement of Connelsville coke, as a matter of fact, began late in November, 1916, and at no time thereafter was there a full movement. The statistics of Connellsville coke shipments, compiled by the *Courier*, show 21,654,502 net tons moved in 1916 and 17,806,-181 tons moved in 1917, a decrease of 3,850,000 net tons, which at 2300 pounds of coke per ton of pig-iron would account for 3,300,000 tons of pig-iron. As a matter of fact, the decrease in pig-iron produced from Connellsville coke was greater than that, because with irregular operation of ovens the quality of coke deteriorated, and with irregular operation of furnaces, including frequent bankings, the coke requirements per ton of pig iron increased. Partial relief was afforded by the output of by-product coke increasing about 3,500,000 tons. The coke troubles did not end with 1917, for conditions were still worse in January and February of this year, and it is doubtful whether even now the rate of pig-iron production is up to the average of 1917. For the future it is a case of having hopes.

There were interesting changes in the distribution as to grades of the pig-iron produced in 1916 and 1917. Basic iron, which constituted about 45 per cent of the total make, decreased in output less than 0.1 per cent, while Bessemer decreased 4.9 per cent. The two grades of steel-making iron together decreased 2.3 per cent. Foundry and ferrosilicon decreased 4.1 per cent, while malleable increased no less than 10.2 per cent, although in 1917 it comprised only 2.3 per cent of the total pig-iron output. Ferromanganese output increased from 221,532 tons to 286,000 tons, or 29 per cent. Adding imports, the apparent supply was 312,-460 tons in 1916 and 331,381 tons in 1917.

Although the production of Bessemer and basic pig iron decreased 2.3 per cent from 1916 to 1917 there appears to have been an increase in steel-ingot production, as partial returns indicate an ingot production of 42,-200,000 tons in 1917, against 41,400,000 tons in 1916. There was hardly an increase in old material available, but more likely a decrease. Stocks of works-scrap were probably cleaned up in 1917 in the effort to make as much steel as possible, while whatever stocks of pig iron existed at the beginning of the year were consumed, probably to the extent of more than a million tons.

The total output of basic iron in 1917 was 17,671,662 tons, and of this 15,056,787 tons was produced by consumers. The amount of iron delivered molten for consumption was 13,696,600 tons, and one may safely assume that practically all of this was produced by the producer-consumer class, so that of the basic iron they produced they used direct 90.97 per cent. The proportion of direct metal charged by the same works was much less, on account of the use of stocks.

While the total production of pig iron decreased 2.0 per cent in 1917, the production of merchant iron increased from 11,253,317 tons to 11,676,513 tons, or by 3.8 per cent, the merchant output in 1917 constituting 30 per cent of the total.

Our April Business

Patriotic Messages from Representatives of the Chemical and Metallurgical Industries

By William H. Nichols

President American Chemical Society, Chairman of the Board, General Chemical Co.

Like the two loans which preceded it, the Third Liberty Loan affords an opportunity for the American people to show the depth of their patriotism by acts rather than words. This, of course, is true of the chemical industry, as it is of all others, and the opportunity thus afforded to co-operate with our Government should be looked upon as a privilege. This applies as much to the humblest workman as it does to those holding the highest position and, judging from the previous campaigns that have come under my observation, they thoroughly appreciate this. In several of the works of this company every single employee subscribed to the second loan, and in all of the works a very large proportion took bonds. I expect that similar results will be reached in the third loan.

The chemical industry has not been found lacking in any respect since our entry into the war and has consistently done its duty. It realizes that much depends upon it, and will make every effort to do its part until the successful termination.

New York City.

* * *

By Paul J. Kruesi.

President Southern Ferro Alloys Co.

The next big victory of the European war must be won here in the United States. Our success in this loan will be magically reflected in the valorous deeds of our brothers and sons in breaking the deadlock on the western front.

Our April business, therefore, is to make an overwhelming success of the Third War Loan—happily named by Mr. McAdoo the Liberty Loan. Of it we must buy and buy, not what each can comfortably digest, but all that our credit will permit when strained as credit was never strained before. Then when we would preen ourselves on our virtuous patriotism we must take a hand in the selling, making the other fellow do what we have first done ourselves.

Never should we forget or allow him to forget how trivial is the curtailment of our ordinary luxuries and comforts as compared with the privations of war imposed on our gallant allies and our own sons at the front.

In no field should more be expected than in those of electrochemistry and metallurgy, than which none has been more stimulated by war and than which none has more at stake in defeating German world-dominion.

Nations like men are accepted at their own estimates until they fail in their own pretensions. From now on France and England expect the morale of their armies to be sustained by ours. Can anyone picture the demoralization and humiliation were we to fail in a bond issue? The end is measurably near whenever we fail, for our armies and our allies will only be beaten when we are.

Away then with so much talk of peace, for the only kind of peace now would be of the "Made in Germany" brand. Away with the faint-hearted who will argue that the "saturation point" in bond sales has been reached! Away to the internment camps with those worst of slackers who claim they are "too busy" to help sell bonds for the liberty they enjoy!

We, who have been the four-year beneficiaries of all their expenditure of blood and treasure, shall we then falter when our brave allies call "Come, and come with all your speed and might"?

Chattanooga, Tenn.

* * *

By G. W. Thompson

President American Institute of Chemical Engineers

I am indeed glad to join in urging those in the chemical industries to do everything in their power to make this, the Third Liberty Loan, a great success. We must subscribe ourselves—we must urge others to subscribe. If we value the really good things in life, if we have affection for our friends and treasure our family ties, if we hold to any principles on which we believe civilization and progress to rest, this is the time to show it. I believe everyone should step forward and seal his devotion to the cause of liberty now. It is the only way.

Brooklyn, N. Y.

* * *

By J. V. N. Dorr,

President The Dorr Co.

The technical man whose work helps the production of essentials feels himself a slacker when he thinks of those going over to pay with their lives for his freedom. His only salvation is to push his work with every ounce of energy and buy Liberty Bonds with every cent he can save.

This is an engineering war and, if there ever was one, it is a "rush job." The chief engineer must not be hampered by lack of funds, and it is up to us not on the firing line to make up for the lack of preparation which we regret by giving every ounce of our energy and every dollar we can save.

America's reply to the Hun offensive must be such an over subscription to this Liberty bond issue that Germany will realize the nation to the last man is behind the war and prepared to win peace only by victory.

It is up to the technical men who realized our danger when the politicians slept to do more than their share in this loan and then start to save for the next.

New York City.

By Colin G. Fink

President American Electrochemical Society

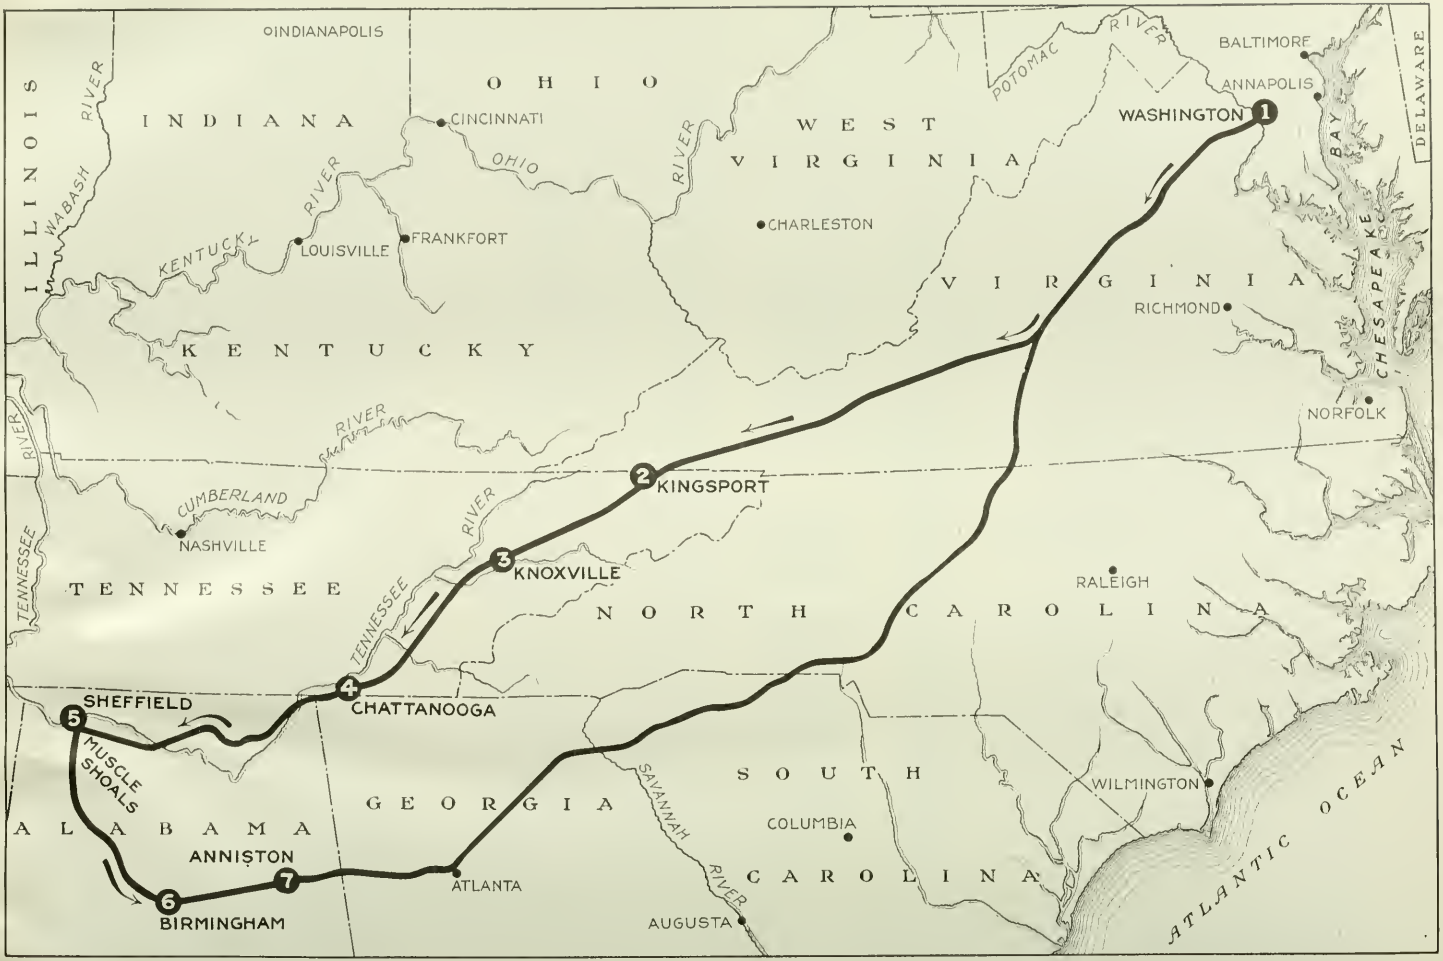
In 1848, when Europe was revolting against monarchies, young Louis Pasteur, while passing through the Place du Panthéon, noticed a little altar with the inscription "Autel de la Patrie." The words kindled his patriotic spirit, and he offered at once his entire humble fortune of 150 francs. The same spirit that pervaded the scientific researches of Pasteur, resulting in so many world successes—this same spirit in its patriotic guise led him to enroll in the National Guards and offer his meager savings besides.

In our appeal to-day to electrochemists and metallurgists to contribute and assist in making the Third Liberty Loan a most emphatic and unparalleled success, we feel thoroughly confident that we need not impress upon them the dire consequences of a possible failure of this loan campaign. A scientific mind will easily appreciate the results. Lack of financial support means defeat. Unless we loan our money to the Government to-day we will have to forfeit it later to the German invader.

President Hibben of Princeton recently remarked to a large audience of engineers, "Germany is winning this war." Our American newspapers have been pursuing a policy of minimizing German successes, with the result that many of our people do not realize that Germany is winning this war. They look upon the task that we have undertaken rather lightly and feel as though the Government will easily handle the situation without any support from the individual. The fact is that our task is a very difficult one. Win we must, and win we shall, but it will require the utmost effort of every man. We must support the Government in every detail of its complex war program. In order to keep our soldiers and sailors well supplied with the very best in munitions and provisions our Government requires money, much money, and more money! Hundreds of ships must be built, thousands of shells and guns manufactured and millions of tons of wheat and meat transported across the Atlantic.

Put your shoulder to the wheel. If you cannot go to France and fight, do all you can to help those that are fighting for you. If you are not yet convinced that you must support the Government financially, don't stop until you are convinced. And if you are convinced, don't stop until you have convinced others. On April 4 it will be just one hundred years since the adoption of our flag by Congress. Let us make this anniversary one worthy of the high ideals our flag represents!

New York City.



ROUTE OF SOUTHERN TRIP, AMERICAN ELECTROCHEMICAL SOCIETY, APRIL 28-MAY 5.

Spring Meeting and Southern Trip of American Electrochemical Society

Tentative Program of Visit to Technical Centers of Tennessee and Alabama, Including Government Projects at Muscle Shoals

WITH the official approval of the Director General of Railroads, the final plans of the American Electrochemical Society for its spring meeting and Southern trip are rapidly nearing completion. For the benefit and information of those who have decided or may yet decide to join the party, we give a provisional program and outline of the trip.

Itinerary

1. Washington, D. C., Sunday, April 28. The party will gather at this point and leave some time late in the afternoon over the route shown in the sketch map on the opposite page. Stops will be made at six points, spending one day or part of a day at each place. The general plan contemplates visits to industrial plants and hydroelectric power stations during the day, with technical sessions in the evenings. Returning, the party will reach Washington some time Sunday morning, May 5.

2. Kingsport, Tenn., Monday, April 29. This community enjoys the distinction of having a complete cycle of chemical and electrochemical industries, interrelated and co-ordinated to an unusual degree.

It is planned to arrive in time for breakfast and spend the day visiting plants, stopping at noon for lunch at Rotherwood Farm. Following are the industries and points of interest: Federal Dyestuff & Chemical Company, electrolytic chlorine plant, Allen cells; Kingsport Brick Corporation; Clinchfield Portland Cement Corporation, Cottrell plant for potash recovery, and steam-electric power plant; Kingsport Extract Corporation, oak and chestnut tanning extracts used by the Kingsport Tanning Corporation; Kingsport Pulp Corporation, paper pulp from spent chips from extract mill; Kingsport Paper Corporation; two alcohol plants.

In the evening there will be a dinner at the Inn, followed by the annual business meeting, motion pictures, dancing, etc. A special exhibit of minerals of the region will be on display.

3. Knoxville District, Tenn., Tuesday, April 30. A preliminary stop will be made at Mascot for breakfast and a visit to the zinc concentrating mill of the American Zinc, Lead & Smelting Company. The oil flotation process is in use here. Arriving at Knoxville, there may be a technical session until lunch time, after which the party will be taken to one of the dam sites of the Aluminum Company of America on the Little Tennessee River. This development is planned to yield 400,000 hp. and is typical of such power possibilities in the region. In the evening there will be a banquet at the Country Club and a lecture by Prof. Switzer of the University of Tennessee on the hydroelectric and industrial resources of the region. This lecture has been specially prepared in anticipation of the meeting.

4. Chattanooga, Tenn., Wednesday, May 1. At this point are the plants of the Kalbfleisch Chemical Company, sulphuric acid and alum; the Chattanooga Gas & Coal Products Company, the Southern Ferro Alloys Company, ferrosilicon, and Wilson & Company, cotton seed oil. There are also a modern bleachery, textile mill and government munition plant. An afternoon boat trip is planned to Hale Bar, where the Tennessee Power Company has a dam and power plant developing 100,000 hp. A complimentary banquet will be served in the evening.

5. Sheffield and Muscle Shoals, Ala., Thursday, May 2. This region is famous for its power possibilities and for the location of two plants for fixation of atmospheric nitrogen. The government is building and will operate a nitrate plant for the synthesis and oxidation of ammonia. The Air Nitrates Corporation is the agent of the Ordnance Department, U. S. A., for the manufacture of ammonium nitrate by the cyanamide process. Construction is well advanced on the nitrate plant and may be under way on the cyanamide plant. In addition to inspecting these plants as far as possible, the party will go by boat up through Muscle Shoals of the Tennessee River. President Wilson recently signed an order for the development of one of the power sites on the shoals to provide 600,000 hp.

6. Birmingham, Ala., Friday, May 3. This district is known for its iron and steel manufacture, to which has been added ferromanganese. The Tennessee Coal, Iron & Railroad Company at Bessemer makes ferromanganese in a blast furnace, and steel by the duplex process. At Ensley there is a by-product coke plant. Plans for this stop are yet to be completed.

7. Anniston, Ala., Saturday, May 4. A short stop of perhaps four hours is planned. At this point are the electric furnace plants of the Anniston Steel Company, making low-phosphorus pig iron and electric steel castings, and the Southern Manganese Corporation, making ferro-manganese and either ferro-chrome or silicon.

The following estimate of expense has been submitted by the railroads, based on carrying 100 persons. Figures include war tax. Transportation, $41.96; upper berth, $15; lower, $19; stateroom or compartment for two, $22 each; drawing room for three, $25 each. Leaving Anniston on the return trip, meals will be served on diner at table d'hote rate of $1.25 per meal. Railroad equipment will comprise one baggage car and pullmans, and it is anticipated that one of the latter will be a combination compartment and observation car.

In making visits to plants it is understood that competitors will not accept the courtesy unless they reciprocate it.

Those expecting to take the trip should notify J. W. Richards, secretary, Lehigh University, South Bethlehem, Pa., making their reservations and sending remittances to him. Any who expect to take only part of the trip should communicate with C. A. Kline, Southern Railway, Washington, D. C.

Readers' Views and Comments

Engineers in Training

To the Editor of Metallurgical & Chemical Engineering

SIR:—I have read with interest Professor Hill's article in the issue of your journal for December 15. It is of especial interest because some three years ago we established a new course at the Massachusetts Institute of Technology, entitled Engineering Administration, and in June of last year we graduated our first class in this course, numbering thirty-seven men. We could have placed a far larger number than those who graduated. Military service has called two-thirds of them at once, and it is rapidly extending its claims to the remainder, but such experience as we have had shows that there is a very specific demand for men who are engineers and who had their attention called to the problems of business management and human relationships which enter into industrial affairs.

DAVIS R. DEWEY.

Cambridge, Mass.

* * *

To the Editor of Metallurgical & Chemical Engineering

SIR: The humanizing and broadening of technical and engineering training are certainly most desirable, but the method of doing this must be most carefully guarded and many of the efforts thus far made are, I think, open to criticism. They most certainly have not attained the desired result and instead of cultivating a desire on the part of engineering students for economic and literary studies have had rather the opposite effect. If, as is sometimes the case, the courses in economics, sociology, etc., are recognized as the "snap" courses, which, though required of engineering students, are taken simply to ease up the program, I question if any satisfactory results will be obtained.

I happen to know of one instance where a young man through sickness was able to attend classes in one such subject for only a month out of the entire semester, yet he was permitted to take the examination without tutoring or doing any work excepting, as he himself put it, cramming for one day before the examination, and passed it. Certainly if this can be done a student is wasting his time by attending lectures throughout an entire semester.

The gist of the subject seems to me is contained in Prof. Hill's conclusion 8, "Non-technical instruction for technical students must be as efficient as technical instruction. Teachers through their own training and experience must be able to relate the non-technical teaching to definitely discover conditions and needs of the technical world itself."

I seriously question the advisability of having engineering students take, for instance, a course in labor problems given by a recent graduate in economics, who has yet to make the real acquaintance of a laboring man, but if such a course can be given by some one, be he an engineer or economist, who has actually been up against the labor problem, such a course would be most valuable.

One solution of the problem is the humanizing of technical subjects by emphasizing the economic, political, and sociological phases, for which there is ample opportunity in most technical courses. For instance, economic geology lends itself admirably to the discussion of many current economic problems cognate to, but not ordinarily included under the head of geology. Such a strictly engineering course as the utilization of fuels certainly offers scope for a discussion of such pertinent economic problems as the recent coal situation. While I think that practically all teachers of engineering agree in the opinion that a liberalizing of our courses is advisable, the best way in which to solve the difficulty is by no means a settled question and many of the experiments now being made are not only not producing the results aimed at, but are taking the time which might better be spent on more distinctly technical subjects.

H. H. STOEK.

Urbana, Ill.

* * *

To the Editor of Metallurgical & Chemical Engineering

Sir:—During recent years a good many people have urged the importance of including courses in business administration, economics, accountancy and other similar subjects in the engineering curriculums with a view to familiarizing undergraduate students with some of the business practices of the commercial world. I have much sympathy with the desire that we turn out graduates from the technical schools who are well prepared to engage in commercial work, and I assume that sooner or later the engineering colleges will give way to the pressure which is likely to be brought to bear upon them for a modification of their curriculums so that they will include an increasing number of non-technical subjects. Five or six years ago the College of Engineering of the University of Illinois completely revised its various curriculums with a view to including a certain number of non-technical electives, in the expectation that students would be given a greater breadth of knowledge and that they might better compete with men of so-called liberal training. If I were to ask the members of our faculty their views of the success of our efforts to "liberalize" our curriculums I am inclined to think that the general opinion would be that the plan has not worked out as we had hoped, largely, perhaps, because the students themselves have too little appreciation of the probable demands of the future to select their electives wisely.

The engineering colleges of the country have been organized to give instruction in the fundamentals of engineering, with some specialization in various technical subjects. On the whole, I think that they have done a pretty good job in the training of men for technical engineering positions. We will all agree, I believe, that the graduates of the engineering schools are not engineers and that the best we can do is to give them the foundation for an engineering career. We are continually endeavoring to bring into the curriculums new technical courses to prepare men in various specialties which have developed as a result of the constant progress that is being made in

engineering science. In addition, as has been indicated, pressure is being brought to bear to include the so-called business courses in the engineering curriculums. Personally, I doubt whether it is possible to make many changes of this sort in a four-year curriculum without some danger that the basic subjects may be given reduced importance. If such changes should be made we may ultimately turn out men who are inadequately prepared either for engineering or for business. Perhaps the final solution of the problem will lie in the extension of the time required for the completion of an engineering course to five or even to six years.

In spite of my doubts regarding the propriety of including much instruction in the principles of business in the four-year engineering curriculum I recognize that the engineer of the future must play a larger part in the social and economic life of the community. During the reconstruction period which will follow the war, the principal problems to be met will be those of a social and economic nature. In one way or another the engineer must play a part in this reconstruction work, and it will undoubtedly be to the advantage of the country if his understanding of these problems is such that his influence may be employed to secure the largest measure of public good.

C. R. RICHARDS.

Urbana, Ill.

Poison Gases in the War

AT the regular March meeting of the Chicago Section of the American Chemical Society, held at the City Club on Friday evening, March 15, 1918, Major S. J. M. AULD, chemical adviser of the British Military Mission, thrilled his audience for about two hours with a description of the part played by gas in modern warfare. He described the first gas attack made by the Germans early in the war and the gallant resistance of the heroic men who met it without even the most primitive means of defense. He proceeded to tell about the development of the gas offensive from the first gas-cloud attack with chlorine to the use of phosgene, various tear and sneeze-producing gases, poison gases, and finally the latest accomplishments with gas shells. The great magnitude with which some of these attacks were carried on may be impressed upon us by learning that hundreds of tons of liquid chlorine have been used in a single attack, and that in some cases the drums of chlorine were placed so closely together that there were three for each two yards along a front of considerable length. The effect of weather conditions, the direction and velocity of the wind, the factor of safety, and many other details were explained.

In recent attacks with gas shells, as many as 35,000 to 50,000 shells have been dropped on a limited acreage in two or three hours. Some of the gas shells contained, in addition to the bursting charge of high explosive, bottles containing liquid, and in some cases even solid chemicals, which would be so completely atomized by the bursting of the shell that they would have the same effects as shells charged with liquefied gases. It was stated that a case was on record in which a shell which failed to explode was examined and found to contain bottles with the original Kahlbaum labels still intact.

Passing to the defensive, the speaker described the development of the gas mask from a simple cloth bandage soaked in various chemicals to the elaborate mask which is now in universal use. As fast as the enemy introduced new devices for gas offense a suitable defense was provided to overcome it. The experience was bitter and costly, but at the present time the idea is prevalent that the worst is over, and that the defense is, in general, developed to a greater degree of efficiency than the offense.

It was very gratifying to hear him say that the mask produced by the Americans, and now in general use at the front, was considered superior to any of the others. Not only are the men provided with masks, but even the horses, mules and carrier pigeons are provided for. In the case of the horses and mules, as these animals breathe through the nose, a mask made of cloth soaked in chemicals is drawn over the nostrils. In the case of the pigeons, however, each bird is not provided with a separate mask. The cages in which they are confined are covered with preparations which prevent any of the objectionable gases reaching the interior.

In the composition of gas masks designed to neutralize the effects of chlorine and phosgene, the chemicals most used are sodium thiosulphate, sodium phenate, activated charcoal, and hexamethylene-tetramine.

Montreal Meeting of Canadian Mining Institute

THE twentieth annual meeting of the Canadian Mining Institute was held at the Windsor Hotel in Montreal, March 6 to 8. The meeting was opened on Wednesday morning, March 6, by Arthur A. Cole, president of the Institute. About 125 to 150 members were present, including several from the United States.

The report of the Council and the financial statement for 1917 were read and adopted.

The presidential address was then delivered by Mr. Cole. He showed how Canada had passed from a borrowing to a self-supporting nation since the war started. He said that one-ninth of the wage earners in Canada in 1915 were employed in the mining and dependent industries and 37.9 per cent of the tonnage supplied to the railways was the product of mines. He mentioned the large number of electric furnaces used in war work for the production of shell steel from turnings, and also the new industries of copper and zinc refining and magnesium production. He thought it highly desirable to keep the gold mines producing in order to maintain a gold reserve. He said one of the main deficiencies in natural resources was the lack of fuel in Central Canada. This could be partly relieved by a greater use of water power. In regard to a proposition put forth that all engineers should combine in a single society, he did not think this advisable owing to the different branches being so specialized, and during times of stress cooperation is easily secured between the executives of the different engineering societies.

A proposal by Dr. A. Stansfield to change the name of the society to the Canadian Mining and Metallurgical Institute was postponed for a year pending the formation of an iron and steel section.

Mr. D. B. Dowling of Ottawa was elected president and Messrs. J. A. Dresser, H. E. T. Haultain and A. E. Whiteside were elected vice presidents.

Councillors were elected by acclamation as follows:

Quebec—Alfred Stansfield, Montreal.

Ontario—N. R. Fisher, Haileybury, Ont.
R. E. Hore, Toronto, Ont.
E. P. Mathewson, Toronto, Ont.
S. B. Wright, Deloro.

Alberta—Jules Charbonnier, Blairmore.
W. P. Williams, Bellevieu.

British Columbia—R. H. Stewart, Vancouver.
George Wilkinson, Victoria.
W. R. Wilson, Fernie.

At the luncheon on Wednesday President Cole announced that a resolution had been unanimously passed by the Council to commemorate the twentieth annual meeting of the Institute by conferring life membership on their first president, Mr. John E. Hardman of Montreal, and Mr. J. Stevenson Brown of Montreal, who was for many years their treasurer.

The report of the Council showed that there had been a large increase in membership during the year. There were 125 members on active service, and eleven members had been killed in action. The total membership was 1118, as against 1066 in 1916.

A smoker was held on Thursday evening, at which the principal event was a paper on the Quebec Bridge, illustrated by lantern slides by Col. C. N. Monsarrat. He described the construction of the bridge completely from the work on the material in the shops to the final opening of the bridge for regular traffic.

The annual dinner was held Friday evening, at which Hon. Martin Burrell was the chief speaker. Mr. Burrell is the Minister of Mines in the new Federal Government.

A long list of papers was read in the three days, including general subjects, coal and fuel, flotation, iron and steel, ferro-alloys, mining, geology, etc.

Among those present at the meetings from the United States were Bradley Stoughton, secretary American Institute of Mining Engineers, New York; Eli T. Conner, Scranton, Pa.; C. Seymour Newcomb, New York, and H. M. Roberts, Minneapolis, Minn.

Toluol from Sulphite Wood-Pulp

IN our last issue we published a note on the possibility of augmenting our supply of toluol by treating the so-called spruce turpentine obtained from sulphite wood-pulp. This material is more properly known as sulphite turpentine or cymene. Its recovery has been made the subject of study by a special committee on toluol of the Technical Association of the Paper & Pulp Industry, and an official report has just been made by Henry E. Fletcher, chairman of the committee, to Captain H. C. Porter of the Ordnance Department recommending the adoption of a method developed by the Hammermill Paper Company. The report, which has reference to the accompanying diagram of the process, is as follows:

The committee has taken up this question by correspondence with various mill operators and chemists, and has come to the conclusion that the best system in vogue at present is the one that has been adopted by the Hammermill Paper Company of Erie, Pa., which has very generously offered the use of this method to any mill. The method is as follows:

Separating the relief gases and liquor, sending the relief gases through the gas cooler to a second separator *B*, shown on the accompanying sketch, this separator taking out the cymene plus a certain quantity of other condensates. You will note the dimensions of this separator for both the intake and discharge are about 6 in. in diameter and the separator itself about 15 in. in diameter and 5 ft. deep. There is a lead baffle-plate placed in the middle of the separator reaching to within a foot of the bottom. In the bottom of the separator is an outlet of about 2 in. diameter, which conducts to a separating tank the cymene, together with an aqueous SO_2 solution. This tank should be equipped with gage glass and indicator cocks. It may be noted here that the gage glass shown is subject to freezing and it would be more advisable to have a stave mortised and a section of from ¼ to ½ inch plate glass inserted from 2 to 3 in. wide and 4 ft. long, answering as a window to the tank itself. From here we draw the aqueous solution of SO_2 from the bottom of the tank back to the acid storage tanks, and the cymene to tanks for the purpose of collecting the same. The more frequently this operation is repeated the better the resulting production will be.

The adoption of the method and the largest possible production of toluol, regardless of cost or profit, is urged on all pulp makers as a patriotic duty.

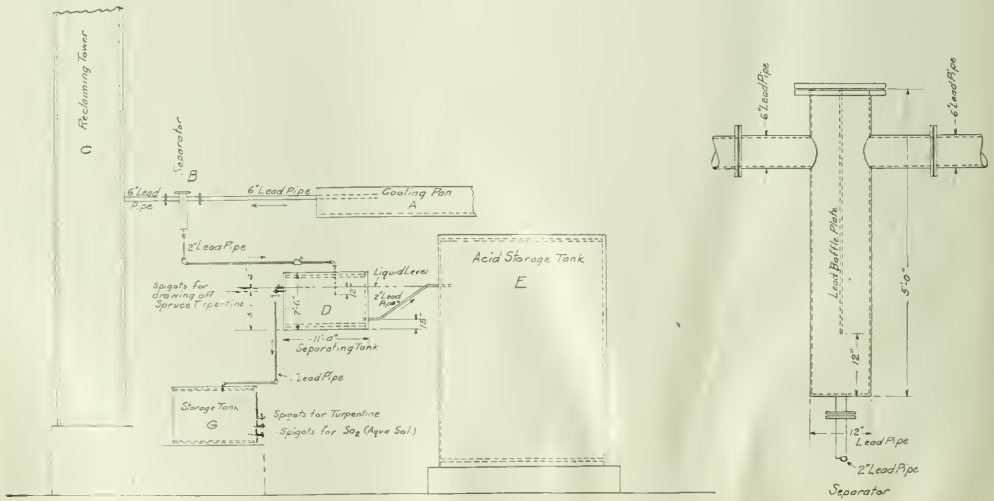


DIAGRAM OF METHOD FOR RECOVERY OF SULPHITE TURPENTINE, OR CYMENE, FOR TOLUOL MANUFACTURE

Hearings on Federal Water-Power Bill

Congressional Committee Is Enlightened on Provisions of New Measure Proposed by the Administration—Prospect Favorable for Enactment

WATER-POWER development under the terms of the so-called Administration bill was the subject of hearings last week before a special power committee of the House of Representatives. To those who have attended hearings in the past when similar measures were under consideration it was apparent that the prospect for successful legislation is now more favorable than at any previous time. There was a notable absence of the professional lobby, and the speakers who appeared before the committee presented sound and impartial facts. The attitude of the committee itself showed a desire to ascertain the truth in order that fair legislation might be speedily enacted. In short, the entire atmosphere was different to that of previous hearings, and there were evidences of unity of desire and purpose.

The course of the proceedings disclosed the particular features of water-power development in which different members of the committee are specially interested. Chairman Sims of Tennessee expressed regret that the bill did not contemplate securing revenue for the federal government, and repeatedly interrogated witnesses on the advisability of making such provision. He was unsuccessful in eliciting affirmative views. Congressman Taylor of Colorado asked all witnesses whether there existed such a thing as a water-power trust, and succeeded in reading into the record a complete denial of the existence of such a combination in the several states represented by the witnesses. Congressman Esch of Wisconsin reverted to parallel provisions in previous bills and interrogated witnesses on the relative merits of the different measures. In practically all cases the replies showed the superiority of the Administration bill.

Among the witnesses there was practical unanimity of opinion that the present bill is the best that has been proposed, and that with a few minor modifications it would be a workable measure. While it does not and will not contain everything that everybody thinks should be in it, there was expressed a willingness on the part of power men to accept the bill with slight modifications.

The Government's Position

Mr. C. O. Merrill, chief engineer of the Forest Service, Department of Agriculture, stated the government's position on the measure. He spoke for the Secretaries of War, Agriculture and the Interior, who are named in the bill as a federal power commission. He spoke in part as follows:

"The industrial expansion caused by the demand for materials and supplies needed in the prosecution of the war, together with the huge financial requirements of the government, have materially changed the pre-war status of the electric power industry. The demand for power has increased notwithstanding increased costs of construction and operation. Increased operating costs have reduced the ratio of income to revenue, and this reduction combined with the decrease in supply of available investment capital has produced a situation with respect to public utilities, among which is electric power development, that merits the early attention of Congress."

He then reviewed the upward trend of prices for the past five years, showing the following advances: Hydraulic machinery, 100 per cent to 150 per cent; electric apparatus, 125 per cent to 150 per cent; steam turbine generators, 150 per cent; water-tube boilers, 170 per cent. In like manner the scarcity of labor and increase in wages have added to costs of construction. Encroachment on fuel-oil reserves and the scarcity of coal have their effect on power development, particularly on the Pacific Coast. All of these items have resulted in increased cost of steam power and have made hydroelectric development more attractive and more necessary.

More Power Needed

"Notwithstanding increased costs of construction and of operation the demand for power has increased, not at a uniform but at an accelerating rate, until during the past two years the annual increment in power generated by commercial central stations alone has been from three to four billion kilowatt-hours, requiring an annual increase in installation of from one and one-half to two million horsepower.

"The demand for power will continue to increase while war continues, in order to supply power to our constantly expanding war industries; and when the war is over, to provide for the extension of public utilities and of the electrochemical industries, for electrification of railroads, and for the multitude of other activities that will accompany the period of reconstruction."

The difficulties in the way of financing power projects were shown by Mr. Merrill, who contended, however, that development could not stop and that legislation should be enacted which would offer the most favorable terms for new projects. He showed the necessity for increased efficiency in existing developments and the desirability of interconnection of isolated plants. In his opinion no considerable development of Eastern water-power will come about except through interconnection of plants over wide territories, in order that the diversity of demand may raise the load factor of the combined system to a point where steam-power competition can be met. This point was forcibly illustrated by a map of California, with its interconnected systems, superposed on the Atlantic States.

Needs of the Future

The Administration bill gives consideration to the needs of the future, Mr. Merrill said, and anticipates the period of reconstruction after the war, when labor will be scarce and mechanical power in greater demand.

Our electrochemical industries, developing under the stimulus of war demands and the cessation of imports, will require increasing amounts of electric power if the United States is to take its place as a competitor in the world's markets or even supply domestic demands. Intensive studies should be made of power sites or groups of sites with relation to particular power needs. Mr. Merrill concluded:

"The shortage of fuel, the overloading of our transportation systems, the demand for industrial power and the unsatisfactory financial situation of our public utilities emphasize as never before the imperative need of immediate, adequate and comprehensive legislation. Our industrial efficiency, both during the war and thereafter, will be increased or diminished according to whether we do or do not make adequate provision for the development of our water-power resources. In view of these circumstances it is submitted that water-power legislation should be considered a war emergency measure and as such should be taken up by Congress and passed at an early date.

In response to questions by members of the committee, Mr. Merrill gave his opinion on the following points:

The terms of a license should be absolutely definite and unchangeable for the entire period of issue. This is quite necessary in order to prevent any uncertainty in the mind of the licensee as to the conditions under which he can operate.

The idea of the rental charge is not to secure revenue for the government, but it is made in return for the issuance of a license. The money thus received is to be used (1) to defray the cost of administration and (2) the possible necessity of recovering excess earnings which it is impossible to reach in any other way.

While the rentals should be nominal they should be greater in those cases where the government contributed land or some other tangible property to a project, and less where the government has nothing to offer but the license. Whatever provision is made should be clearly stated in the license before it is accepted by the licensee. It was Mr. Merrill's opinion that it would be a better fiscal policy to charge a rental which would be nominal and which would not reduce earnings below a fair return or increase rates to the consumer. As between getting revenue for the government and reducing rates to the consumer, rental charges should operate in favor of the latter.

Rate regulation on interstate business should be left to the several State authorities and handled locally as long as local authorities show the ability to act and as long as there is no disagreement between States. Federal jurisdiction should come in when other authority is insufficient.

The recapture clause is considered to be the most important in the bill, and it was Mr. Merrill's opinion that the basis for recapture should be the actual legitimate original cost of the property plus additions, less any funds accumulated in unappropriated surplus or for the purpose of providing for depreciation of equipment or amortization of investment. The price should allow nothing, however, for any unearned increment in value of the property, good will, going-value, or expected profit.

Improving a Navigable River

Mr. Henry J. Pierce of the Washington Irrigation & Development Company explained to the committee the features of a project for the development of power, improvement of navigation and irrigation of land at Priest Rapids on the Columbia River. This stream is now navigable for steamers of 1000 tons capacity for 400 miles from its mouth at the Pacific Ocean. The construction of a proposed dam and locks would add 200 miles of navigable waters, through a region almost without railroad facilities. The dam would cost $25,000,000, and will permit of the development of 250,000 hp. throughout the year, and an additional 250,000 hp. or more during the high-water period. This period corresponds with the irrigation season, so that by a fortunate coincidence there would be water for irrigation and power for lifting it to the upper lands.

The witness showed a map of the United States and its navigable waterways. Practically all are in the East. On the other hand, 62 per cent of the area of eleven public-domain states in the West is under federal control, where over 60 per cent of the wasting water powers of the country are located. Mr. Pierce dwelt on the hazardous nature of waterpower undertakings and the necessity for removing onerous terms from licenses for development. In his opinion the bill under consideration was fair toward the investor and operator, while protecting public interest. He asked that a holder of a priority permit be protected in all expenditures made in good faith in the development of water power and that he be given the preference to a permit as against others who have not expended time nor money. He also asked that any tax imposed should be on the actual power developed, and that in case the license is to be renewed the original licensee have the first right.

Mr. Calvert Townley, assistant to the president of the Westinghouse Electric & Manufacturing Company, repeated part of a statement made before the United States Chamber of Commerce. It was his opinion that even favorable legislation would not stimulate water-power development because of competition with the steam turbine and the comparatively low cost of construction of a steam-electric plant.

The Investor's Viewpoint

Mr. E. K. Hall, vice-president of the Electric Bond & Share Company discussed the bill in its financial aspects. From the point of view of the investor there are two fundamental defects in the bill. The contract has been made definite and the investor knows what he is getting and what is expected of him. He is assured of the enjoyment of the privilege for fifty years and of the return of his capital at the end of that period if the government at that time wishes to recapture the project. But if the government does not want to take the property he must continue to run it under an indeterminate and uncertain tenure. He cannot issue refunding bonds, because he does not know how long he may be allowed to hold the property. For this reason Mr. Hall urged that if the government did not wish to take or transfer the property on the expiration of the license it should be reissued to the holder for a term of thirty years.

The other defect was the provision for recapture of

the property at the expiration of the license on payment of the net investment. This assured the investor the return of what he had put into the project and had not already taken out besides his fair profit, but did not allow him to profit by the enhanced value of the land. In all other businesses the investor was allowed, besides what fair current profit he could make, to benefit by an increase in the value of the property while in his hands. In response to an inquiry by a member of the committee, Mr. Hall said he considered this the best bill yet offered.

Power Development in California

Mr. John A. Britton, vice-president and general manager of the Pacific Gas & Electric Company, showed the relation of hydroelectric development in California to the upbuilding of the state. He joined other witnesses in saying that the administration waterpower bill was good in its main features, but that some provision should be made to except from the full terms of the bill those projects which were only in part—and sometimes a very small part—constructed on government land. He cited two cases in California in support of his contention. In one case a reservoir project includes 38 acres of "forest reserve," which is really a rocky, barren waste, but which is flooded when the reservoir is full. In another projected development of 250,000 hp., less than 2 per cent of the land belongs to the government, and yet if the project is developed in such a way as to omit this 2 per cent, there would be a large loss in potential power. It would be criminal not to develop the full amount of power, and yet the obligation that would result under present rules and regulations of the departments would prevent financing the project. Mr. Merrill had previously suggested the following amendment to the bill to cover such cases as Mr. Britton spoke of.

"In issuing licenses for a part only of a complete project, or for complete projects of not more than 50 hp. capacity, the commission may, in its discretion, waive such conditions, provisions, and requirements of this act as it may deem equitable in the circumstances."

Mr. Britton laid stress on the necessity of hydroelectric development as a measure for conservation of coal or oil—resources which are destroyed when used once, as against the perennial and inexhaustible use of waterpower. He showed that the licensee can get only a fair return on his investment, and not even that unless he makes a success of the venture. In the latter case the government has an opportunity to recapture the project, and perhaps turn it over to a municipality.

Mr. H. T. Freeman of the Connecticut River Company showed the necessity for government action if such projects as those of his company are to come to fruition. He was asked if a waterpower trust existed in Connecticut, and replied that, on the contrary, there was the keenest competition.

Mr. John J. Harris, president of the Big Horn Canyon Irrigation & Power Company, Montana, described his project, which combined the features of power development, flood control, transportation and irrigation. He thought that local organizations of men with small resources might be handicapped by the provision of the bill allowing only three years for preliminary work on a project. He showed the committee what such preliminary work meant to his concern, which had been engaged for six years.

Mr. Charles N. Chadwick spoke in behalf of House Bill 9681, which seeks to provide for a broad administration of national water resources. It calls for a national board of water conservation to study rainfall, flood control, navigation and power development. Mr. Chadwick felt that this bill affords a better opportunity for broad treatment of the subject than does the administration water-power bill.

Mr. C. F. Kelley, counsel for the Montana Power Company, said that the Administration bill was generally acceptable as a measure that would encourage the development of water-power. He objected to recapture on the repayment of "net investment" to the licensee, and asked for "just compensation." Mr. Charles E. Stuart of the United States Fuel Administration told the committee of the efforts of the Administration to conserve fuel.

Mr. A. P. Morrison of the Electro Metallurgical Company, Niagara Falls, spoke from the viewpoint of the large user of power, to whom stability of service and rates were of prime importance. He felt that such consumers were not sufficiently protected in the bill. Their investment might easily be greater than that of the licensee, and yet at the expiration of the license they might be subject to readjustments in rates that would be prohibitive.

Mr. A. H. Houghton of the Conservation Committee of New York thought there would be some conflict between the Administration bill and the New York laws, and suggested amendments. The term of five years for the executive officer of the federal commission should be changed to ten or fifteen years. Mr. William B. Matthews of Los Angeles, which has its own municipal plant, said that a license to a municipality should be perpetual. The federal commission should not have jurisdiction over rates and service of a municipal corporation where power is used for state or municipal purposes.

Secretary Lane Advocates Immediate Development

Secretary Lane of the Interior Department was an important witness toward the close of the hearings. He pointed out that there is still on the books a statute under which revocable permits are granted, but that the men who have money to invest in water-power propositions are not willing to allow any official to say when the investment they have made shall be thrown to the winds. The result, he said, has been that we have stood for five years almost entirely without development of one of our great resources.

The secretary then cited the interdependence of the West and the East in water-power development. As an example he gave the recent action of the Anaconda Copper Mining Co. in undertaking the manufacture of ferromanganese. This was made possible by the development of water power in Montana near deposits of low-grade manganese ores. The effect of this single development had been to release shipping formerly used in bringing manganese to this country, but now available for war business. Furthermore, ferromanganese manufactured in Montana was used directly in the industries of Pittsburgh.

"If we had money enough," he continued, "if this were not a time of war, if we could think in the terms

of money that we are now thinking in, or if, four or five years ago, Congress had been willing to expend hundreds of millions of dollars in the development of water power as it is forced now to spend billions of dollars for war, it would be a wise thing to put a large part of the public revenues into such projects where they are found to be needed.

Government Ownership Feasible

"I have no doubt in my own mind but that such schemes as water-power schemes are perfectly practicable from a governmental standpoint, no matter what your sympathies may be respecting government ownership, as a rule, of large utilities. A thing that is as well standardized as a water-power scheme can be operated successfully by the Government; but I do not take it that this is a practicable proposition at this time, nor probably will it be for many years to come, and it is necessary that there should be real development, and that soon." Mr. Lane elaborated his point of view in regard to the impracticability of devoting Government funds at this time to the building of water-power plants by discussing the immense demands being made upon the treasury now and in prospect.

Answering questions by Chairman Sims, Secretary Lane said if there is a determination by Congress that there shall be water-power development, for instance, along the Columbia River, or the Snake River, or the Colorado River, for the production of low-grade manganese, or for the development of nitrates, either for gunpowder or for fertilizer, and such works could not be financed, that "it is the duty of the Federal Government at this time to help out the proposition and put it on its feet." He added: "I am not sympathetic generally with the idea of having the Government lend money to private enterprises, because it is a hard thing to get it back. But I am very much in sympathy with the Government doing what it pleases with its own money, provided it knows where it is going and what it wants and how that money can be properly handled; and I am not afraid at all of the Government undertaking the development of the water-power propositions, because we have had some experience with them in the Reclamation Service. The Salt River proposition which I have turned over to the water users is practically paying its own way now out of the power developed at the Roosevelt dam. That was a venture at the time. All of these propositions are gambles. That is one reason why a man who puts his money into a water-power project has got to have very real consideration. He is a developer, and every man who is a pioneer of any kind takes the risk, and for his risk he ought to be compensated."

In reply to a question as to whether it will be possible for water-power plants to be built in time to be of service before the war is over, Secretary Lane said: "I have no expectation that this war will be over before water-power projects such as many that we know of can be developed. I think you have got to look at that thing with a long range."

Expansion Predicted in Electrochemical Industries

Secretary Lane predicted a great expansion of the electrochemical industries of the United States. "We ought to appreciate more fully now that after this war is over there will be the necessity of larger electrical development than we have ever had before in connection with the chemical industries of the United States.

"We have never been a chemical nation, and that side of our scientific development has been overlooked. Germany has been the chemical nation of the world. We are now taking that up, and probably there is more interest today in chemistry in the United States than there has ever been before. We have in Washington today hundreds of chemists working in connection with the Bureau of Mines and the Ordnance Department. They have been gathered from all parts of the country. A great many of them are Germans, many of them educated abroad in German institutions, showing how far ahead Germany has been in this particular line of science. It is quite manifest to me that there has got to be very large hydroelectric development if we are going to develop to the highest degree along the lines of chemistry. Perhaps the best sphere for a young man for the next twenty-five years will be as an electrochemical engineer in the United States. The water powers ought to be developed now, not only with the idea of taking care of a process that is a commercially successful proposition, but for the purpose of experimenting and discovering what can be done. We ought to foster that kind of thing."

United States Chamber of Commerce Referendum on Water-Power Legislation

The Chamber of Commerce of the United States announces the results of a referendum to more than 1000 commercial organizations on a series of recommendations relating to water-power development. The following recommendations were approved by sweeping majorities:

> That federal legislation encouraging the development of waterpowers should at once be enacted; that authority to grant permits should be vested in an administrative department; that the permit period should be at least fifty years, any shorter period being at the applicant's option; that tolls should attach only to use of public lands or benefits derived from headwater improvements; that permittees should be entitled to acquire the right to use public lands forming only a small and incidental part of the development; that recapture should be exercised only upon payment of fair and just compensation; that, if recapture is not exercised, the investment of the permittee should be adequately protected; that rates and service should be regulated by State commissions where the service is intrastate, with federal regulation only where several States are directly concerned and do not agree, or there is no State commission; that if any jurisdiction to regulate the issuance of securities is exercised it should be solely by the State; that no preference should be granted as between applicants amounting to a subsidy from the Government creating unequal competition.

These provisions are practically contained in the Administration bill now before the special waterpower committee of the House. They were regarded as the vital points on which there might be a difference of opinion, and in sending out the referendum the Chamber was careful to present arguments for and against each of the ten items. Consequently the vote may be considered indicative of intelligent opinion formed by the business men of the country after a careful study of the subject. Some negative votes were cast on each item, but the number was insignificant and the net result may be looked upon as a unanimous demand for the development of water power and approval of the proposed procedure.

Standardization of Rare-Metal Thermocouples*

By PAUL D. FOOTE, T. R. HARRISON and C. O. FAIRCHILD
United States Bureau of Standards

MANY technical industries use such extensive installations of pyrometer equipment that it is frequently desirable to place the general supervision and maintenance of this equipment in the hands of a technical expert. The duty of this engineer and his assistants is to calibrate the instruments, check frequently the accuracy and constancy of the pyrometers, make small repairs, construct thermocouples, and install new apparatus when required. He should be familiar with all methods of temperature measurement, temperature control, etc., and various chemical and metallurgical processes, so that he may suggest advisedly new methods and improvements in temperature measuring apparatus for the particular process in question.

A man of the required ability will necessarily command a good salary, but it has been the experience of many companies that it is poor economy to place work of this character in the hands of inexperienced men. If it is believed that a perfect working system of temperature control can save a certain plant any considerable sum each year, a fair percentage of this amount can be profitably spent in securing a competent, technically-trained man and in equipping a modern laboratory for the maintenance of the pyrometer installation. With the proper organization and equipment, exceedingly valuable investigational work may be carried on, new opportunities will be found for increasing the value and uniformity of the finished product and the cost or production may be lowered by reducing the number of failures to a minimum.

Type of Tests Performed in the Industrial Laboratory

The modern industrial plant employs various types of pyrometers including the high-temperature mercury thermometer, the resistance thermometer, the radiation pyrometer, the optical pyrometer, and the thermocouple, etc. Each type of instrument has its advantages for various processes. The calibration, upkeep and use of each class of instrument should be carefully considered.

The present paper deals with the laboratory side of one phase of this problem, namely, thermocouple installations. This is, however, probably the most important subject with which the pyrometer laboratory has to deal. The calibration of optical and radiation pyrometers requires rather elaborate equipment and is so susceptible to errors that this type of testing is usually not advisable for the ordinary technical laboratory. It is better to send such instruments to the maker or to the Bureau of Standards for calibration. Furthermore, the number of calibrations of optical or radiation pyrometers required per year by any one company is, in general, comparatively small since these instruments do not deteriorate with use as do thermocouples. A single calibration of a good optical or radiation pyrometer should hold for years if the instrument is properly cared for. On the other hand, the calibrations of the thermocouples must be repeatedly checked, for contamination and use may alter the temp.-e.m.f. relation, and the life of base metal couples is frequently so short that the calibration of new couples becomes a serious problem in the case of large installations.

Thermocouple testing may be divided into two general classes, primary standardization and secondary standardization. In primary standardization the thermocouple is calibrated directly in terms of certain fixed temperatures, defined by the melting or freezing points of a series of chemically pure metals. In a secondary standardization the couple under test is compared with another couple which has been calibrated as above. Primary standardization is not recommended for most industrial laboratories, as it requires a considerable amount of extra apparatus and laboratory technique. The Bureau of Standards undertakes work of this character for a nominal fee and recommends that the industrial laboratory maintain at least two standard rare-metal couples, which may be submitted to the bureau at intervals for a primary calibration. All the couples are then calibrated in the industrial laboratory by comparison with these standards. However, a number of companies prefer to do their own primary standardization and for this reason the best methods for primary calibrations as well as secondary calibrations are discussed below.

Standardization of Rare-Metal Couples

The rare-metal couple may be purchased completely mounted in a porcelain or quartz tube with the cold junction arranged to operate at room temperature or at the temperature of melting ice. The latter method is preferable for the highest accuracy, but the former method is usually sufficient for most requirements. A suitable ice box is described later.

If desired, the thermocouple wire may be purchased from the platinum refiners and made into couples in the laboratory. One wire should be platinum and the other an alloy of 10 per cent rhodium with platinum, both of the highest possible purity. For general work, wires 0.5 mm. or 0.6 mm. in diameter and 100 cm. long serve satisfactorily. A shorter length may be used if the cold junction is operated at room temperature or in connection with the compensating leads to be described in a later article in a paragraph on cold junctions.

The hot junction is formed by fusing the two wires in an oxy-gas flame or small electric arc. With a little practice a neat joint can be made which should be in the form of a bead about 1 mm. diameter. The wires are threaded through two-hole porcelain insulators and placed inside of a thin-walled protecting tube of quartz or of porcelain, glazed on the outside only. The two

*The first of a series of two articles dealing with the pyrometer laboratory for industrial purposes. The second article will deal with base-metal thermocouples

free ends of the couple are mounted in the ice box (See section on cold junction ice box) and from this point copper leads are carried to the potentiometer.

ANNEALING

Before standardization the couple should be removed from the mounting and the entire length of wire electrically annealed for a few minutes at about 1500 deg. C. This treatment eliminates the electromotive forces which otherwise would be developed between the hard and soft portions of the wire. When rare-metal couples have been contaminated by long continued use they may be often restored to their original condition by annealing for an hour or more at this high temperature. Impurities, such as iron oxide, which have accumulated on the surface of the wires may be removed by 50 per cent nitric or hydrochloric acid. In case long-continued alternate heating and treatment with acid fail to restore sections of the couple, these badly contaminated portions should be cut out and the couple fused together again with as small a junction as possible.

For annealing electrically the couple is suspended between two binding posts and sufficient current passed through it to raise the temperature of the wire to about 1500 deg. C. A couple made of wires 0.6 mm. in diameter requires about 14 amp., 0.5 mm. about 12.5 amp. and 0.4 mm. about 10 amp.

In general the contaminated portions do not glow as brightly as the more pure sections of the wire. If the wire is not badly contaminated the darker spots will gradually disappear. If more extreme local treatment is required, the contaminated portions may be wound into a small spiral and the couple heated as before. The coiled portion of the wire loses less heat per unit length by radiation and hence can be maintained at the desired temperature while the rest of the wire is heated to a dull red. Usually foreign matter produces a gray or dark appearance of the wire when cold, and these contaminated sections are stiffer than the uncontaminated wire.

While couples may be often restored to their original condition by annealing, the disappearance of the gray spots on the wire does not prove absolutely that the couple is free from contamination. The absence of contamination is shown, however, by a homogeneity test. Where high accuracy is required a homogeneity test should be made.

HOMOGENEITY TEST

For work of precision each wire of the couple must be uniform in chemical composition and physical condition throughout its entire length. The magnitude of the e.m.f. developed by the couple depends upon the composition of the couple in the region of the temperature gradient. The e. m. f. developed by an inhomogeneous couple is not necessarily a measure of the temperature of the hot junction. In fact it is a measure of the temperature of the hot junction only when the region of inhomogeneity lies entirely outside of the region of temperature gradient. Such a fortunate condition would be obtained very rarely in practice.

Suppose, for example, in a furnace 40 cm. long, that the temperature is uniform and at 1000 deg. C. over the central 20 cm. of the furnace and that the temperature drops, linearly with distance, to 0 deg. C., over the remaining 10 cm. on each side. Omitting consideration of conduction losses, a homogeneous couple would show the true temperature of any desired portion of this furnace, and the temperature indicated would be that corresponding to the position of the hot junction of the couple.

Consider the use of an inhomogeneous couple in which the wires are badly contaminated for a length of 5 cm. from the hot junction. This couple would give the correct temperature of the central portion of the furnace when immersed to any depth between 15 and 30 cm. because for such depths of immersion the inhomogeneous portion of the couple lies wholly within the region of temperature uniformity. It would not be possible to measure with this couple the temperature of any portion of the furnace less than 15 cm. from the outside because the region of inhomogeneity would lie in the region of temperature gradient. Under such conditions the couple acts as a compound or differential couple and it is impossible to predict how much in error its indications may be since the magnitude of the error depends upon the amount of contamination and the steepness and location of the temperature gradient.

The above example illustrates the fact that the reading of an inhomogeneous couple depends upon the depth of immersion and does not, except by accident, indicate the temperature of the hot junction. It would be impossible to measure, by means of an inhomogeneous couple, the temperature of any portion of a furnace which was non-uniformly heated, unless the couple were calibrated in the position used.

For a homogeneity test a short length of each thermocouple wire is selected as a standard reference specimen. These lengths may be cut from the uncontaminated cold-junction ends of the couple and one set may be used repeatedly for various couples of the same type. One end of the standard wire (for example the pure platinum wire) is touched to a section of the corresponding wire of the thermocouple and the e.m.f. is observed between the cold-junction end of the thermocouple wire and the free end of the standard wire when the point of contact between the standard and the thermocouple is heated to some convenient high temperature, maintained constant.

The point of contact of the two wires is then moved to a different section of the thermocouple wire and the process continued until the platinum wire of the thermocouple is completely explored. The process is repeated for the alloy wire of the couple, except that in this case the speciment of the alloy wire is used as the standard.

If e is the maximum difference in microvolts between the two readings of e. m. f. made along one wire of the thermocouple and s the value of the thermoelectric power for the couple (microvolts per degree of temperature) then the maximum error usually possible in the use of the couple due to inhomogeneity of this wire is e/s in deg., provided the temperature of the hot junction in general use does not exceed that employed in the homogeneity test.

If the temperature difference between the hot and cold junctions during the homogeneity test were $t_1 - t_2$, and during the actual use of the couple $t_1' - t_2'$, the maximum error possible in the use of the couple, due to inhomogeneity of this wire, is approximately $\frac{t_1' - t_2'}{t_1 - t_2} \frac{e}{s}$ degrees. Similar conditions hold for the other wire of the couple.

The effects of inhomogeneity in both wires may be either subtractive or additive so that it is evident that to quantitatively correct temperature readings for errors due to inhomogeneity is practically impossible. Merely qualitative results can be obtained from tests of this nature. If the variations in e.m.f. observed during the homogeneity test are less than 5 microvolts for $t_1 - t_2 = 500$ deg. C., the couple can be relied upon for precision work. If certain sections of the couple show larger e. m. f. these sections should be treated by annealing until their condition is satisfactory, or should be cut away in case they cannot be brought to a proper condition.

The point of contact between the couple wire and the standard wire may be heated by a Bunsen flame, but a more satisfactory method is as follows: The heater consists of a glass (preferably pyrex glass) T tube having the top and leg of the T wound with resistance wire through which sufficient current is passed to heat this tube to about 400 deg. C. One of the wires of the thermocouple is threaded through the top of the T and the standard wire is brought into contact with the couple by threading it through the lower part of the T. The end of the standard wire is bent into a small hook through which the couple passes, sufficient tension being given to the standard wire to secure good electrical contact with the couple. The free ends of the

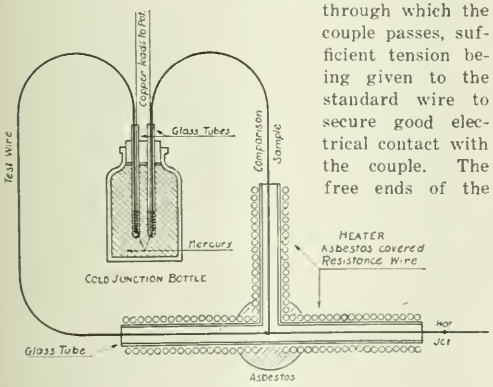

FIG. 1. APPARATUS FOR HOMOGENEITY TEST OF RARE METAL COUPLES

couple wire and the standard are maintained at the same temperature by use of a cold-junction box.

The cold-junction box may consist of a small bottle of mercury into which dip two small glass tubes closed at the lower end. A few drops of mercury are placed in each tube and the free end of the couple wire is inserted into one tube and free end of the standard into the other tube. Copper wires making contact with the platinum wires by means of the mercury inside the tubes lead to the millivoltmeter or potentiometer. The copper and platinum must not come in electrical contact except in the mercury. Readings of e. m. f. are made for various points of contact along the couple by pulling the couple through the T tube and allowing a minute or so for temperature equilibrium at each new position. Figure 1 illustrates the apparatus used for homogeneity tests.

The Laboratory Potentiometer:

In precision thermocouple calibration a potentiometer especially designed for this type of work should be used.

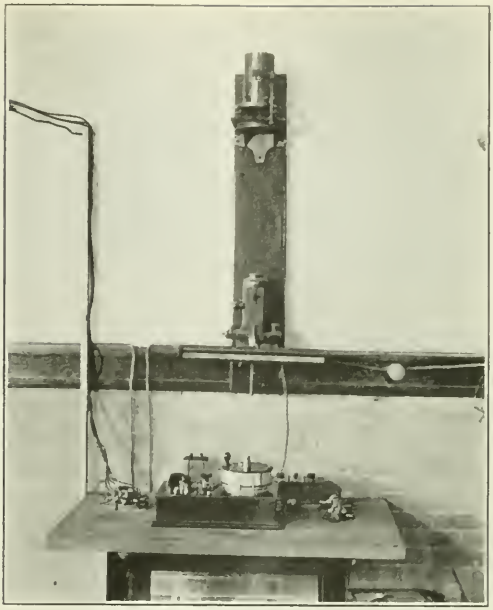

FIG. 2. A LABORATORY POTENTIOMETER AND ACCESSORIES

Figure 2 illustrates a complete potentiometer installation, including galvanometer and reading scale. The wiring diagram is given in Figure 3.

In order to eliminate the effect of accidental thermal e.m.f.'s developed in the instrument itself two double-pole double-throw switches are used, one in the main battery circuit and one in the e. m. f. circuit. Readings are made with the two switches thrown first in one direction and then in the other direction. In one case the parasitic e.m.f.'s arising in the potentiometer and galvanometer are additive to that of the couple and in the other case they are subtractive, whence a mean of the two readings gives the true e. m. f. of the thermocouple circuit. In comparing the e.m.f.'s of two or more couples, readings should be taken in the following order and the final means obtained, used as the calibration data.

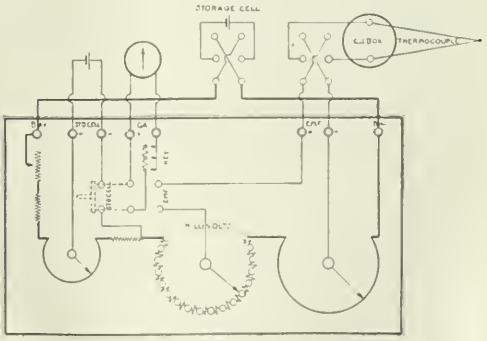

FIG. 3. WIRING DIAGRAM OF POTENTIOMETER INSTALLATION

Position of Switches	Couple I	Couple II	Couple III
Normal	1	2	3
Reversed	6	5	4
Normal	7	8	9
Reversed	12	11	10
	mean emf.	mean emf.	mean emf.

Care should be taken that the battery switch is in the normal position when balancing the instrument against the standard cell. The main battery of the potentiometer should be a 2-volt storage cell of about 50 amp. hr. capacity and should be charged every three months. Details in regard to the use and care of a potentiometer are given in the instruction manual furnished with the instrument.

Cold-Junction Ice Box

A satisfactory ice box is obtained by fitting a small battery jar with a fiber or hard rubber cover. Through the cover are inserted several small glass tubes closed at the lower end, two tubes for each couple used. A few drops of mercury are placed in each tube and the battery jar is kept filled with clean ice shaved or ground into a wet snow.

The cold junction ends of the couples are inserted, one in each tube, and copper wires lead from the mercury to the potentiometer. The copper wires should be insulated from the couple wires throughout the length of the glass tubes except where they dip into the mercury. This precaution is very important, for if the copper and platinum (or alloy wire) are in electrical contact at the top of the glass tubes, the whole value of the ice box is lost.

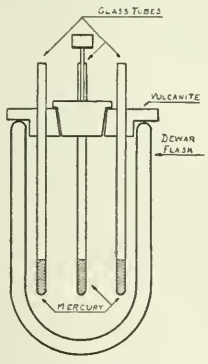

FIG. 4. THERMOCOUPLE ICE BOX

The glass tubes should be kept clean and dry inside. A little moisture and dirt at the bottom of the tube will form a galvanic cell giving a large e. m. f. This trouble is easily detected by the rapid change in e. m. f. immediately after closing the potentiometer key, due to the polarization of this small cell. It is desirable, but not necessary, to replace the battery jar by a Dewar flask or thermos bottle having a large mouth, since the ice melts more slowly in this form of container. Figure 4 shows a diagrammatic sketch of an ice box suitable for thermocouple work.

Calibration of Primary Standards

When a crucible of pure molten metal is allowed to cool, the cooling curve obtained by plotting temperature of the metal versus time is continuous until the freezing point (or transformation point) is reached. During freezing the metal gives out enough internal latent heat to supply the losses due to radiation and convection, and the temperature of the metal remains constant until all the metal has frozen. In this region of the cooling curve, the curve is parallel to the time axis. After the metal has frozen it cools in a somewhat similar manner as when completely molten. Figure 5 shows cooling and heating curves for several metals.

The freezing point of copper (1083 deg. C.) is clearly indicated by the flat portion of the second curve. On heating a metal the temperature gradually increases with time until the melting point is reached. The temperature of the metal then remains constant, as shown in Figure 5 until all the metal is melted, after which the temperature again increases with time.

The temperatures at which melting and freezing occur are identical for pure metals. When molten antimony is allowed to cool the temperature usually falls below the freezing point before the metal starts to freeze, a phenomenon known as under-cooling. When any of the metal starts to solidify, however, the temperature immediately rises to the freezing point as shown in Figure 5, unless the under-cooling has proceeded too far. Under-cooling may be greatly reduced by stirring the metal for an instant just as the freezing point is approached.

Aluminium does not appear to have as well defined a melting or freezing point as do many other metals. The material is "pasty" over a small temperature range. This may be due to the presence of impurities and is probably not a characteristic of the pure metal.

In the primary calibration of rare-metal couples use is made of the type of cooling and heating curves above described. The couple, properly protected, is immersed in the molten metal which is then allowed to cool slowly. The e. m. f. of the couple is observed as frequently as possible and the time noted for each observation. These values are plotted and the e. m. f. corresponding to the flat portion of the cooling curve is the e. m. f. at the freezing point of the metal. A similar process may be carried through by melting the metal.

The temp.—e. m. f. relation for the platinum, platinum-rhodium couple has the following form: In the

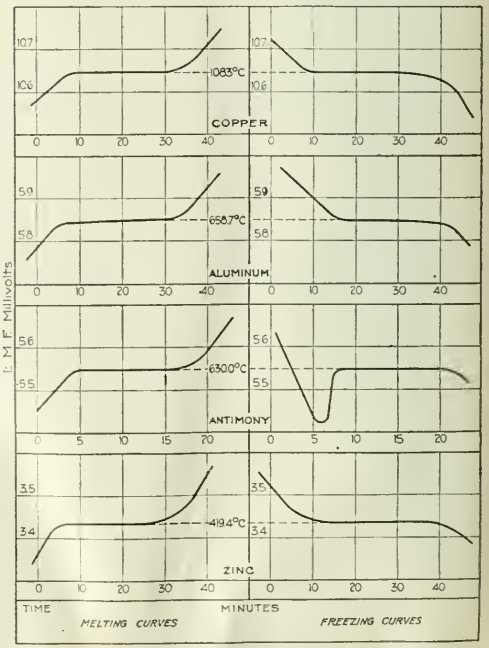

FIG. 5. TYPICAL HEATING AND COOLING CURVES

temperature range 300 deg. to 1200 deg. C., $e = a+bt+ct^2$ where e=e. m. f., t=temp. deg. C. of the hot junction of the couple (cold junction= 0 deg. C.), and a, b, and c are constants. Three standard points are required to determine a, b, and c for any particular couple. These fixed temperatures may be the melting or freezing points of zinc 419.4 deg. C., antimony 630 deg. C., or aluminium 658.7 deg. C. and copper 1083 deg. C. The metals must be of the highest possible purity. This is especially the case with antimony, which is very difficult to obtain in sufficient degree of purity. The Bureau of Standards furnishes standard samples of zinc, aluminium, and copper (also tin, see Circular No. 66), with certified melting points. Aluminium of the highest obtainable purity is recommended in preference to antimony for the industrial laboratory. The following shows the method of obtaining the constants a, b and c:

OBSERVED CALIBRATION POINTS

Metal	Temperature	emf.
Zinc	419.4°C	3.436 millivolts
Aluminium	658.7	5.839
Copper	1083.	10.561

Whence, from the above equation it follows that:

$$3.436 = a + (419.4)b + (419.4)^2c.$$
$$5.839 = a + (658.7)b + (658.7)^2c.$$
$$10.561 = a + (1083)b + (1083)^2c.$$

These three equations are solved for a, b, c, giving a=—0.3240, b=+0.008277, c=+0.000001638. The final equation for this couple thus becomes:

$$e = -0.3240 + 0.008277t + 0.000001638t^2$$

where e is the e. m. f. in millivolts corresponding to a hot-junction temperature of t deg. C., and a cold junction temperature of 0 deg. C. From this equation e may be computed for various values of t deg. C., (for example 300 deg. C.=2.306 millivolts; 350 deg. C. =2.774; 400 deg. C.=3.249; 1200 deg. C.=11.967, etc.) and a curve or table of e versus t deg. C. may be constructed. Using this curve or table one may readily find the temperature corresponding to any e. m. f. observed in the future use of the couple.

The above equation serves to determine the temperature scale in the interval from 300 deg. C. to 1200 deg. C. An entirely different equation must be used for points below 300 deg. C. For discussion of this see Burges and LaChatelier "Measurement of High Temperatures." At temperatures higher than 1200 deg. C. the following corrections must be added to the temperatures given by the above equation. These corrections apply for all platinum—ninety platinum—ten rhodium, thermocouples.

Temperature computed from parabolic equation	Correction to add
1200°C	0°C
1300	2
1400	6
1500	14
1600	25
1700	37

The standard metal may be used in an Acheson graphite crucible (Dixon graphite is also satisfactory for copper) the inside diameter of which is slightly less at the bottom than at the top. Convenient inside dimensions are about 5 cm. diameter and 15 cm. deep. For use with the 50 cm. 3 metal samples furnished by the Bureau of Standards a crucible 3.5 cm. inside diameter and 8 cm. deep is recommended. Crucibles should be fitted with a cover having a small hole in the center through which the couple is inserted. The crucible may be heated either in an electric or gas furnace. Figure 6 shows a convenient form of electric furnace. The bottom of the furnace must be tightly closed with asbestos wool as the slightest current of air will rapidly oxidize the crucible. If this simple precaution is omitted, in a very short time the bottom of the crucible will burn completely away allowing the metal to run out and become contaminated. Also the furnace will be seriously damaged by the molten metal.

If a gas furnace is used the crucible should be placed inside a length of iron pipe, capped at the bottom, and the space between the crucible and the pipe should be filled with powdered or flaked graphite. Instead of an iron pipe, a larger crucible of Dixon graphite or fireclay may be used. In all cases the top of the crucible and the surface of the metal should be covered with 2 or 3 cm. of powdered or flaked graphite. This is especially important with copper, as the oxide of copper formed on exposure of the hot metal to the air is soluble in the metal and thus lowers the melting point to an appreciable extent.

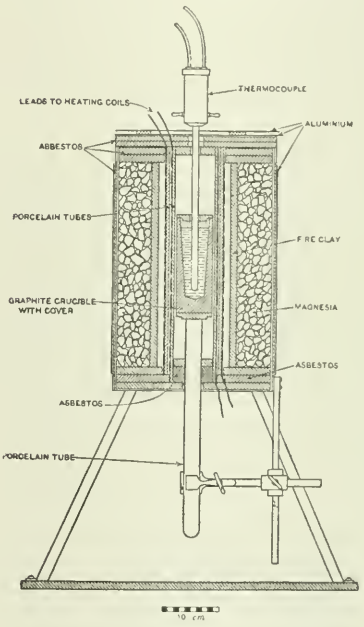

FIG. 6. ELECTRIC FURNACE FOR STANDARDIZING THERMOCOUPLES BY MELTING-POINT METHODS

PROTECTING TUBE FOR RARE-METAL COUPLE

The thermocouple must not come in direct contact with the molten metal or metallic vapors. A suitable protecting tube is of porcelain glazed on the outside and closed at the lower end. The diameter of the tube may be 1 cm. or less and the walls should be thin. The couple wires are again protected and insulated from each other by small porcelain insulating tubes, or by the standard two-hole porcelain tubing sold for this purpose.

It is good practice to remove the couple and insulators from the outside protecting tube when immersing the latter in the molten metal as frequently the tubes are broken in this operation. This precaution saves the couple in case such an accident takes place. The procedure is therefore as follows: Hold the pyrometer tube above the furnace in the heated air until it takes up this temperature. Gradually lower it into the furnace

until the top of the crucible is reached. When thoroughly heated gently immerse it in the metal. Observe that the tube is not broken. If in doubt insert a small porcelain tube inside the pyrometer tube. If the outer tube is broken the small tube will be discolored or contaminated with the metal. Another method of detecting a broken tube is to pull it out of the metal and if intact replace it before it has had time to cool. After having determined that the pyrometer tube is good, insert the thermocouple. This should be done very slowly as the rapid insertion of the cold thermocouple may break the protecting tube. After the metal has frozen the protecting tube should be withdrawn or the furnace should be immediately heated for a melting point determination. An immersed tube which is allowed to cool with the metal far below the melting point is usually broken. For a small temperature range below the melting point the tube can be readily withdrawn.

Either glazed porcelain or fused quartz (silica) protecting tubes may be used in this work. With aluminium, however, the protecting tube must be itself protected from the metal. This is easily done by making a tubular sheath of Acheson graphite, with walls about 1 mm. thick, which slips over the quartz or porcelain tube. It is better to have one set of tubes for each metal, but when necessary to use the same tube in various metals this can be done if care is taken to thoroughly clean the tube with nitric and hydrochloric acid. The greatest care should be exercised to see that no dirt of any kind gets inside the pyrometer tubes. Dust or carbon inside the tubes, when heated, forms a reducing atmosphere which acts upon the silica, freeing silicon which rapidly attacks the platinum.

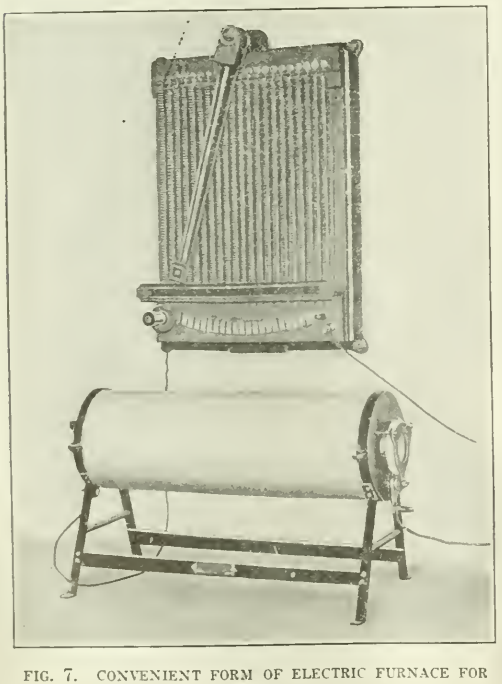

FIG. 7. CONVENIENT FORM OF ELECTRIC FURNACE FOR INTERCOMPARING RARE METAL COUPLES

Secondary or Comparison Calibration of Rare-Metal Couples

The secondary method, as follows, is recommended for industrial laboratories. One or preferably two rare-metal couples of wire about one meter in length and 0.6 mm. in diameter are maintained as primary standards. These couples should be submitted to the Bureau of Standards for test and certification at intervals depending upon the amount of use to which they are put, or whenever contamination is suspected. The couples to be tested are compared with these standards. Suitable electric furnaces for such comparison tests are now available, designed to operate on either 110 or 220 volts and may be obtained complete with adjustable rheostat for regulating the current, as shown in Fig. 7. The furnace consists of a porcelain tube wound with platinum foil, surrounded by a larger porcelain tube around which is packed thermal insulating material. A convenient size of heating tube is 1 in. by 18 in., but larger sizes can be secured if desired. The furnace should be kept clean and should not be used for testing base-metal couples, annealing iron rods, or other processes likely to cause contamination.

The rare-metal couples to be calibrated are removed from the protecting tubes and insulating tubes and annealed as described previously. The insulating tubes are then replaced and the couples are tested without the protecting tubes, if the furnace is clean. The hot junctions of all the couples, the standard couple and the couples under test, are connected together with as good thermal contact as possible. The junction may be fastened together with a small platinum wire and then wrapped with platinum foil. Since the couple wires are thus in electrical contact at the hot junction, they must not be allowed to touch one another at any other point. The use of platinum foil around the hot junction is to reduce temperature gradients to a minimum. If the couples are tested in the protecting tubes, this precaution becomes still more important.

The cold junctions of all the couples are maintained at 0 deg. C. If three couples are being compared with one standard, the readings should be taken in the following order:

Reversing Switch	Standard	No. 1	No. 2	No. 3
Normal	1	2	3	4
Reversed	8	7	6	5
Normal	9	10	11	12
Reversed	16	15	14	13
Means				

The means of the observations on each couple are taken and the temperature is obtained from the reading of the standard couple. Several calibration points are made in this manner in the range 300 deg. C. to 1200 deg. C. These are plotted, temp. vs. e.m.f. and a smooth curve is drawn through the experimental points for each couple. If it is inconvenient or undesirable to use a cold junction temperature of 0 deg. C. for the couples under test, any other constant temperature may be employed. This can be measured by means of a mercury thermometer. It is nearly as essential to know the temperature of the cold junction as that of the hot junction since the magnitude of the e.m.f. observed depends upon both temperatures.

A subsequent article will deal with the calibration of base-metal couples and other general pyrometer laboratory data.

The Design and Operation of a Small Kjellin Furnace*

Manufacture of Electric Steel for Stamp-Mill Shoes and Dies on the Witwatersrand, South Africa

By GEORGE H. STANLEY and W. BUCHANAN

As one result of the war and consequent restriction of imports, the mining industry in South Africa found it imperative to utilize to the fullest extent all local resources in plant and material to supply its urgent necessities. Among the latter, obviously, stamp-battery shoes and dies occupy a prominent place, a regular supply to the extent of about 7500 tons annually being essential to the conduct of gold milling. In order to consider the possibility of the manufacture of shoes and dies locally, a committee was appointed in February, 1916, at the instance of the Chemical, Metallurgical and Mining Society of South Africa.

This committee reported that it was of opinion that such manufacture was possible by utilizing existing accumulations of scrap shoes and dies, and strongly recommended that it be undertaken at once in view of increasing shortage and rapid rise in price.

After considering various means of production, such as forging scrap, or melting in coke or gas-fired crucibles, open-hearth furnaces or electric arc furnaces, it appeared that an electric induction furnace of the Kjellin type was most practicable. It was practicable to construct it locally from existing material and of the required capacity. The Victoria Falls and Transvaal Power Company could supply current suitable with some modification for a small furnace, and requiring comparatively inexpensive electrical arrangements. Alternatively, suitable generators, to be motor-driven, were available. This type of furnace does not, however, lend itself to working up miscellaneous scrap in the same way as an arc (or combination induction-resistance) furnace, but this was not contemplated at the immediate time. It requires no electrodes, and could be constructed of locally available materials in from six to eight weeks. Unfortunately, 50-cycle current requires such thin furnace walls that the thermal efficiency is reduced by large radiation, and therefore large furnaces are impossible. Again, the best channel section is narrow and deep, which requires small-sized scrap. It was therefore necessary to install a frequency converter, producing 10 to 15-cycle current.

It is useful to compare the economic efficiency of the induction furnace, including a frequency converter, with that of the arc type plus electrodes. A modern motor-generator of about 200 kw. capacity, converting three-phase, 50-cycle supply into single-phase at low frequency would have a full load efficiency of at least 80 per cent, and since it requires about 800 electrical units to melt one ton of steel, the loss by transformation is 200 units, which at, say 0.6d. (1.2c.) per unit amounts to 10s. ($2.40) per ton of castings. The consumption of graphite electrodes in furnaces of the Heroult type is at least 15 lb. per ton of steel melted, while in the Stassano and Rennerfelt types, where the electrodes are not in contact with the metal or slag, it is about 10 lb. The price of graphite electrodes has very considerably advanced, and is now at least 1s. ($0.24) per lb., so that the cost is 15s. ($3.60) and 10s. ($2.40) per ton of steel respectively. The capital cost of induction furnace with converter would be about the same as that of the corresponding arc furnace, with its transformer, and electrode regulating gear.

Material Available

There is at every mine an accumulation of worn and scrapped shoes and dies amounting in the aggregate to several thousands of tons, and on the average about 15 per cent of the new weight of shoes and dies is ultimately discarded as scrap. Much of this has been utilized for such purposes as flooring, but is mostly recoverable if necessary. There is consequently many months' supply for the furnace installed, but it is also possible to utilize other scrap of similar composition and suitable shape, difference in composition being rectified by suitable additions. Manganese is available in high manganese-steel scrap, silicon and carbon in selected cast-iron pig and scrap, carbon as gas-retort carbon and charcoal, while aluminium is stocked in considerable quantity.

Analyses of imported shoes and dies are given in Table I.

Table I

	A. Kowel Die	Orenstein-Koppel Die	Orenstein-Koppel Shoe	Orenstein-Koppel Shoe	Fraser & Chalmers Die	Cammell-Laird Die	J. J. Colver Die	J. J. Colver Shoe	Sanderson-Newbolt

Plant Installation

It appeared probable that a furnace of about one ton capacity would be suitable. If this poured a heat of two-thirds of its contents three times per day, two tons of steel would be obtained, equivalent to 12 to 24 shoes and dies, depending on the individual weight. This is roughly 10 per cent of the total requirement and very probably could be considerably increased, possibly even doubled, by quicker working. This, at any rate, would put beyond question the suitability of the product, and enable working costs to be more nearly ascertained.

The furnace itself was constructed[1] as shown in Fig. 1, but with some slight modifications; the cores and yokes being built up of old transformer iron, and the primary winding, consisting of copper cable insulated with asbestos tape, being placed in a three-inch coil

*A combined abstract of two papers: Electric Furnace Manufacture of Shoes and Dies on the Witwatersrand, by Geo. H. Stanley. *Jour. Chem., Met.* and Min. Soc. of S. Africa, Sept., 1917, and The First Electric Steel-Melting Furnace in South Africa, by W. Buchanan. *Jour. S. African Met. of Elec. Eng.*, Sept., 1917. This part of the papers relates to operation. Features of design will be presented in a second article.

[1]Details of the design are given later in the article

space between the core and inner walls of the furnace. Between the inner wall and the coil itself a cylindrical shield of asbestos sheet was placed with the idea of protecting the coil in case of the molten steel breaking through the wall.

Instead of elaborate water-cooling arrangements, air circulation alone is depended on for cooling the coil, a ventilating cowl of asbestos millboard—not shown in the drawing—being placed over the center and connected to a chimney passing through the roof. At first a compressed air jet was used to increase the air velocity, but seemed to have no appreciable effect on cooling and was therefore discarded. This arrangement effects a very considerable simplification of design, and does not seem to be attended with serious drawbacks.

The body of the furnace is built up of special radial and rebated lumps (Fig. 2) tied over all with steel hoops, terminating in screwed ends passing through yokes, so that tightening or loosening could be effected. Any further iron or steel work being very undesirable from the electro-magnetic point of view, the plates between these and the brickwork were of monel metal—another feature believed to be novel—in fact, this alloy is used, replacing iron or steel, wherever desirable and possible in this furnace. To keep the power factor as high as possible, the interior wall was made 8 in. thick (plus, of course, the thickness of the lining), while the outer brickwork has a thickness of 9 in., in each case laid in fireclay. The cover bricks are of radial shape, 2 in. thick, and to prevent breaking or cracking are clamped as shown in Fig. 3 by means of monel metal rod flattened and bent over at the ends, and with screws put through so that they may be tightened up. A strip between them serves for lifting when required.

In the annular trough formed between the inner and outer walls the working lining of the hearth is placed. One of the initial difficulties was the selection of a suitable material for this lining. Knowing that reasonably pure magnesite occurred in the country, it was originally intended to construct the lining of calcined magnesite, but owing to the difficulty of satisfactorily calcining this material at the temperature under which it is to be used, the first lining was made by ramming ganister, prepared by grinding together pure quartz with a small amount of fireclay, round a sectional wooden template.

Operation of the Plant

After removing the template, which left an annular trough 16 in. deep by 5½ in. wide, the lining was allowed to dry naturally overnight and then warmed up by a fire bucket inside the central core space, and finally by burning wood on the hearth. Then, in order to further heat and start the furnace, coals of discarded wire haulage rope—again a novelty—were placed in the hearth, the iron yoke fitted into place and current switched on. However, as the temperature rose, the expansion of the ganister caused it to crack in several places and strip away from the brick of the inner wall. Attempts to repair gave no promise of success, so that the attempt was abandoned. Moreover, the wire rope became badly oxidized, particularly near the tap hole which had not been closed causing it eventually to break circuit. All the inner wall lining was therefore taken out and replaced by tar-chromite mixture, rammed by hot iron rammers, and a fresh start made with wire rope as before, but with a reducing atmosphere maintained by burning wood in the hearth. The temperature was raised very gradually for nearly three days till the rope began to melt, but with the unexpected result that since melting started at one point only, the melted metal at once dropped to the bottom of the hearth and broke circuit. Attempts to bridge the break by driving in iron bars and adding turnings, etc., were only temporarily successful, and finally fluid cast iron was obtained and poured into the furnace. This restored conductivity, but some of it solidified on top of the wire rope coil, hiding from view the hearth-bottom which, as subsequently appeared, contained a small quantity of fluid metal, while the solid top separated from it was only red hot and heated by radiation from that below. As a result, the temperature of the liquid

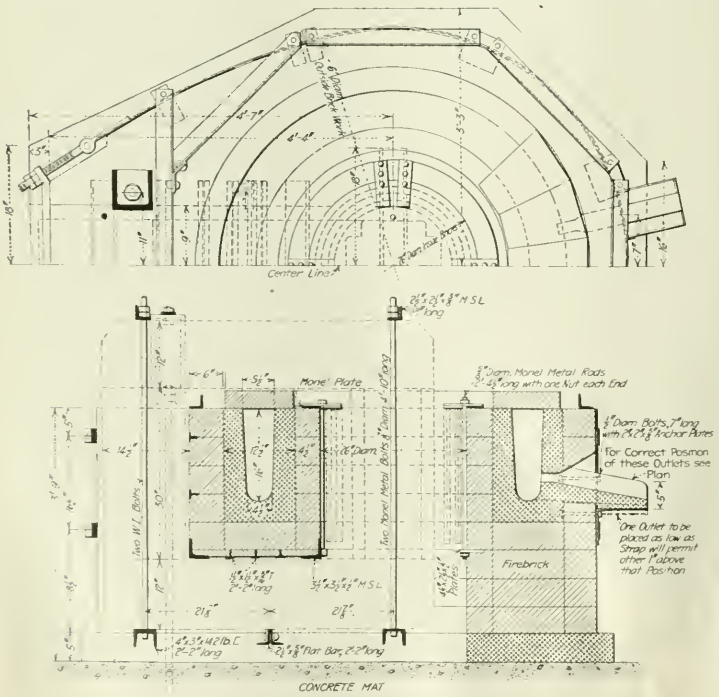

FIG. 1. PLAN AND SECTIONAL ELEVATION OF KJELLIN FURNACE

metal was so increased that the inner chromite lining was melted through and the metal escaped on the floor.

The corrosion had been considerably assisted by chemical action by the carbon and other elements in the iron reacting with the lining, so that the escaping metal was rich in chromium: it seems possible that this idea might be devoloped as a method for the pro-

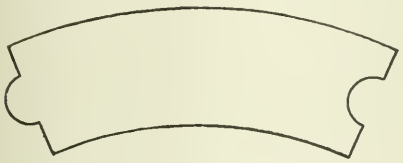

FIG. 2. FURNACE BRICK

duction of chrome alloys. Considerable damage was done to the coil and transformer iron, and while this was being repaired the opportunity was taken to obtain some of the magnesite bricks and have them ground down to prepare a fresh lining. This was ultimately made up of a lining of chromite inside the brickwork, faced internally with about 2 in. of tar-magnesite mixture. The heating was started as before with wire rope and molten cast iron, and this time with success. As a result several successful casts were made, though with severe trouble in the management of the tap hole, which broke out several times. Ultimately the furnace was cooled down and the tap-hole re-made entirely, but two days after starting the metal again broke out through the inner wall, damaging the transformer more severely than before, necessitating another long stoppage.

While the repairs were in progress, another difficulty was remedied by modifying the shape of the template to give a hearth 7½ in. x 13 in., and so facilitate the feeding of awkwardly shaped pieces of scrap, though doubtless at the cost of a certain loss of electrical efficiency. It may be mentioned that the slag adhering to the walls reduces the free space for feeding, so that the original width of 5 in. sometimes made feeding extremely difficult.

The new lining, except for about 4 in. of chromite underneath, was rammed entirely of magnesite, which, although known to be impure, was the only supply then available.

After starting up as before the furnace worked relatively smoothly for over a week, and if the output was small it was chiefly due to inexperience; as a matter of fact it only averaged about one cast per day. However, the lining cracked and it was emptied to avoid risk of damaging the transformer.

Magnesite Linings

During this time it has been found that nearly pure magnesite was obtainable, the analyses of four samples showing:

Silica (SiO_2)	1.0	1.05	0.45	2.5
Lime (CaO)	0.08	0.20	trace	0.10

A consignment of this was obtained and calcined, but unfortunately it could only be done at the same time and using the same machinery and kilns as for silica bricks. Consequently considerable contamination occurred, and analyses of different consignments used for lining showed silica present from 9.7 per cent to 14.0 per cent. However, subsequent relinings were carried out with this material, at first using tar as a binder, but later employing a mixture of clay and boric acid, recommended by Professor Arnold, of Sheffield University, in the proportion of 140 lb. clay, 20 lb. boric acid and 40 lb. water to 2040 lb. of magnesite; but it was found necessary to largely increase the amount of water.

Decarburization of the Melt

Commencing with the employment of a magnesite lining, improvement was rapid, and early this year operations became nearly normal. Early troubles were largely due to alternate heating and cooling of the lining due to labor trouble and other enforced stoppages mentioned, and as these have been eliminated or lessened the frequency of tapping and consequently the output has increased till for some time between 1900 and 2000 lb. of castings have been regularly obtained every eight hours. Now the period is being reduced to six hours. Apart from the material of the lining, the chief difficulty in the early stages was oxidation of the metal and consequent loss of carbon and manganese content, which besides softening it, made it much less fusible. This was due to the rust on the scrap, to scale formed during preheating, and partly also to admission of air to the furnace by defective covers. When, in the early stages, a heat lasted sometimes 24 hours or more, it is not surprising that on occasion all the carbon was lost and dead soft iron was produced. This has been remedied by more rapid working, and by keeping a little charcoal on top of the metal in the furnace. Indeed, the charcoal is so marked in its effect in facilitating the working of the furnace that it is difficult to make the furnace hands (Cape colored men) use it in sufficient moderation, and for a long time carbon in the steel was nearly always much too high, generally 1.1 per cent to 1.3 per cent. Even now it does not seem advisable to dispense with charcoal entirely, but by exercising proper care, carbon can be kept at about the desired figure, while by stopping the formation of oxide the furnace walls are preserved to a considerable extent from corrosion and their life increased.

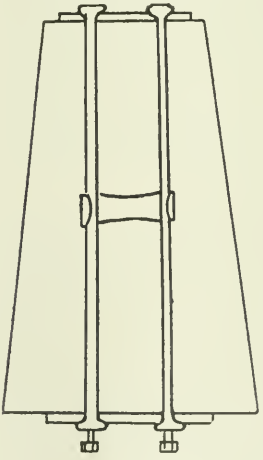

FIG. 3. COVER BRICK

The chief furnace trouble at the present is the formation of a "crust" of solid metal more or less completely covering the surface of the molten metal. It is not serious if noticed and dealt with in time, but if allowed to increase by building up and feeding more metal it entails much labor and risk of damage to the walls in detaching it. It does not seem to be of any

assistance to try and make a slag, which indeed is difficult to keep fluid, but sometimes to clean the metal a little fluorspar has been added. Another difficulty, in a recent lining, arose from trying to incline the trough towards the tap hole. This reduced the cross-section of steel too seriously at the other side, and caused several breakages of circuit after tapping, probably due to the "pinch" effect, so that the tap-hole had to be raised. However, having the hearth level leaves a ring of metal to be removed every time a stationary furnace has to be completely tapped out for relining. In normal operation, lining and working proceed as follows:

Relining

The old lining having been stripped out immediately after it had cooled sufficiently, the bottom is rammed into place with hot rammers, little by little, and then the template supported in position. This is constructed so that when the ramming is completed the sides can collapse to some extent, thus loosening and facilitating withdrawal. (Lately the bottom has been made rather more V-shaped, so as to keep a continuous starting ring with less weight of metal.) The walls are then rammed in the same manner, and when complete, about twelve hours from the last tapping, the template is withdrawn, the walls completed with a course of flat radial brick, the coil of rope inserted and the yoke replaced. This occupies about three hours more. Current is then switched on, and the furnace is ready for more foundry metal within thirty hours of the last cast. Three ladles, about 500 lb. in all, are then carried across from the foundry and poured in. Generally this solidifies, but in two or three hours is molten again and the feeding of scrap commences.

Melting

The scrap has previously been heated to redness in the furnace attached to the drying stove, and is transferred by means of tongs to the electric furnace, feeding in several places through spaces left by removing a cover block. This is kept up for two or three hours more, about 2000 lb. of scrap having been charged, after which the metal is left at rest to become hotter and ready for casting, no metal being ordinarily fed within one hour of tapping. At this stage the required amount of pig iron and manganese steel is added. Towards the end most of the slag is skimmed off on the end of flat iron bars, and shortly afterwards the top tap-hole is opened in the usual manner by drilling out its center, which has been plugged by a friable mixture of magnesite, coal dust and clay (the hole itself being lined with the same mixture as the furnace). When the flow of metal has practically ceased it is stopped by placing two or three suitable flat pieces of scrap against the tap-hole inside the furnace. Any metal in the tap-hole is removed while hot. This removal is important, or a break-away may be caused subsequently, and the hole is then made up again. Thereafter charging goes on as before, but with scrap only, except for the additions at the end. The first two or three heats are cast into dies, since the high carbon, sulphur and phosphorus content from the cast iron would lead to breakage of shanks if cast into shoes; thereafter three shoes and five or six dies, or latterly even eight shoes are made per cast.

Cracks and holes appear in due course in the lining, but so far it has not been found possible to patch them successfully. It is often stated in textbooks that this is done, but inquiries have failed to elicit how.

In order to save time in ramming, a pneumatic hammer tool was used recently, and apparently used too well. Nearly 50 per cent increased weight of magnesite was rammed into the lining, and when this was heated up it expanded and cracked badly. This method is still in course of trial, but with a lighter blow, and seems likely to save considerable time, *e.g.*, the interval between the final cast of the old lining and first cast of the new is reduced to about forty hours only.

Pouring and Casting

A tilting furnace would obviously have prevented much trouble with regard to the tap-hole and tapping, and could doubtless have been made, but in view of the necessity of keeping initial outlay as small as possible the fixed furnace was decided upon. This usually necessitates the intervention of a ladle between the furnace and molds, the metal being tapped into the ladle and poured thence into the molds. Originally, therefore, a ladle and suitable handling gear was installed, the intention being to pour over the lip. However, owing largely perhaps to slow and inexperienced handling in the early stages, a very large proportion of the steel solidified in the ladle, forming skulls which constituted so much waste, it being impossible with the available appliances even to break them up for remelting. In addition, frequent relining entailed much expense and delay. Hand ladles of smaller size were then substituted for a time, three being used in rotation at each cast. This arrangement reduced the loss to some extent, though it was still large, but there was still much lining to be done and, moreover, it was very awkward to operate in the somewhat confined space. Therefore, after some other trials the present method was arrived at.

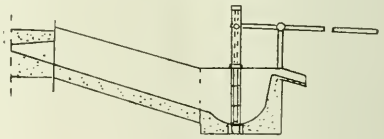

FIG. 4. FORE-HEARTH

As shown in the illustration, Fig. 4, the tapping spout is somewhat lengthened, and has attached to its end a box of sheet steel provided with a bottom outlet through a fireclay nozzle, and forming a kind of forehearth. The spout and forehearth are lined as usual and, of course, patched and faced after every cast. The outlet can be closed by means of a fireclay plug, as usual in bottom teeming steel ladles, this plug being carried on a rod actuated by a lever in front, worked by hand. Directly underneath this, and at right angles to the spout, is a line of rails on which a series of flat cars carries the molds, so that they can be moved in turn underneath the nozzle. This has considerably raised the daily output, and on several days over 3 tons of castings have been produced.

It was soon ascertained that it was much easier and simpler to cast onto iron molds (with sand tops);

moreover, the operation requires less skill. Consequently nearly all the production has been made in this manner. But, while overcoming certain troubles, the use of iron molds introduces others, *e.g.*, when, in the case of shoes, the bottom of the mold, forming the shank of the shoe, is worn and rough, it tends to grip the solidified metal and prevent its normal shrinking, thus leading sometimes to cracking at the butt. In use, this crank rapidly results in breakage. This may be overcome in future by molding the shanks only in sand.

The present arrangement is shown (Fig. 5), and it will be seen that there is very little molding work required. To diminish this still further, trials have been made of tops formed of fire brick and of cast iron, but so far the balance of advantage seems to lie with those

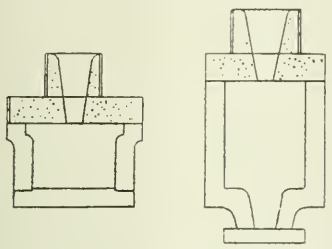

FIG. 5. METAL MOLDS WITH SAND TOPS

of sand. As soon as the mold is filled a little sand is thrown on top and a weight (usually an old shoe) placed on top of that, so that the metal solidifies under a slight pressure. Ultimately the feeder head is knocked off while still hot and the casting is stripped. When cold enough, any fins due to the split molds are trimmed off by hammers, and any irregularity where the head broke off dealt with in the same manner. To obtain sound castings a small amount of aluminium is placed in each mold before casting, this being found more effective than adding it in the furnace.

Temperatures

Attempts were made to ascertain the temperature in the furnace before casting, both by means of a platinum-rhodium thermocouple and Féry radiation pyrometers. Neither method is satisfactory for continuous use; the former is rapidly destroyed and the latter is difficult to use in spite of being mounted directly above the furnace, because the slag chills directly the cover is moved and the metal cools appreciably while slag is being skimmed. The eye, or the old "cutting the rod" test is therefore still depended upon.

In addition to the melting furnace itself, a coal-fired preheating furnace is installed in order to economize electrical power by heating the scrap to redness before it is charged into the electrical furnace, and so arranged that it also heats the drying stove.

The Product

It must be confessed that at first the quality of the product was very irregular, a large proportion being honeycombed with blow-holes, and the carbon content varying widely in different casts. With increasing experience this is being regularized, and a more uniform quality turned out.

Carbon is determined in every cast by the Eggertz color test, a sample for the purpose being dipped out from the furnace on the end of a rod, and at intervals a complete analysis is made. Some of these are given below, and it will be seen that carbon is frequently rather high.

Carbon .	64	1 18	1 12	774	1 07	1 13
Silicon	14	357	149	120	186	20
Manganese	56	600	670	352	52	24
Phosphorus	054	069	043	042		021
Sulphur	043	059	062	057		022
Chromium . .	.20	.14	13	. .		022

Under the circumstances it is scarcely surprising that the percentage of shank breakage among shoes has been somewhat high, but of course the reports so far received from the users mainly relate to the earlier product. Investigation showed that high carbon certainly seemed to predispose to breaking, and why this is so can readily be understood. Excess cementite, although very hard, is also very brittle and apt to break under shock; while if the mass is of eutectoid constitution with about 0.9 per cent carbon, no separate cementite exists, and we have a strong homogeneous material. Even up to 1 per cent carbon the amount of free cementite is scarcely appreciable, and it is therefore endeavored to keep the carbon below that point. If a hydraulic press were available to forge the metal somewhat, it would without doubt be fully equal to the imported. At present, by the use of large headers in casting, it is endeavored to keep the metal as sound as possible, but forging is impossible.

Men Wanted for Engineer Replacement Regiment

THE First Replacement Regiment of Engineers was organized at Washington Barracks, D. C., on December 14, 1917. Its specific purpose is to keep all engineering units of the army at full enlistment strength during the period of this war. This regiment has not only the responsibility of finding men to fill up depleted ranks but it must also fit them to step into the work of trained, efficient and disciplined soldiers.

The men are first given infantry drills which gradually gives way to specific technical training. The engineer soldiers must know how to tie all the important kinds of knots and lashings, to build spar and truss bridges, to construct revetments, dig trenches, place wire entanglements, construct machine-gun emplacements, build pontoon bridges and to construct roads. They must also know the methods of demolition, sapping and mining. Specialized training in lithography, zincography, surveying, mapping, photography, carpentry, blacksmithing, electricity and machinery are also given to those qualified for further training in any of these branches.

Male citizens in the United States who are physically fit, and between the ages of 18 and 21, and 31 and 40, are eligible to join the regiment by voluntary enlistment.

Applicants for enlistment should write to the Commanding Officer, 1st Replacement Regiment Engineers, Room 107, Headquarters Building, Post of Washington Barracks, D. C., for application blank and instructions.

Central Stations and the Manufacture of Electrochemical Products*

By C. A. Winder

TO LOOK at this subject from a central station viewpoint is to consider the economic value of the electrochemist as a customer rather than the engineering questions surrounding the actual use of electric power by him. In the past the central station engineer seems to have taken the attitude along with the apparatus manufacturer that the electrochemist was, strictly speaking, a chemist delving in a field he was perhaps only meagerly acquainted with.

For five years I have been intimately associated with the electrochemists and feel safe in stating that as electrical engineers, especially insofar as their own requirements are concerned, they are as a general rule well qualified; more so in many cases than those with whom they deal. I say this to justify some of the claims they have made which will enter into some of the phases of the situation which I will discuss further on.

But, before considering the economic side of this question, it might be well to look into the power consumption of the various well known electrochemical products, especially those consuming relatively large quantities of power and where the power enters into the chemical reaction rather than furnishing mechanical power. This will determine to a great extent the location of the industry and the price the industry can pay for its power.

This class of electrochemicals will include in the order of their importance, the following: aluminium, ferro-alloys, calcium carbide, artificial abrasives, alkali, chlorine, phosphorus, sodium, carbon disulphide, graphite and similar products. These are all products that are indispensable to the arts and manfactures and at the same time their use has been greatly increased by war demands; demands, by the way, which to a great extent, will not continue after the declaration of peace.

Power Consumption for Various Products

Aluminium consumes the largest amount of power per pound of finished product (approximately 12½ kilowatt hours) and is perhaps more dependent upon the low cost of power than any of the other above mentioned products. Based upon the calculations of electrochemists in a position to know, it seems possible for aluminium manufacture to exist a thousand miles from the center of gravity of its distribution provided power can be obtained at from $20 to $25 a kw.-yr. In this product we have an ideal combination of high consumption of power and low shipping weight.

Next in order considering energy consumption per pound of product is perhaps the artificial abrasives, whose consumption is about half that of aluminium, but the shipping weight of the finished material is quite high. Here we have an industry that cannot stand long freight hauls even with unheard of low prices of power. If the haul of the finished material were two thousand miles, it is doubtful if an artificial abrasive plant could exist where power was free. I do not believe that this industry can stand more than a five hundred mile haul under the prevailing prices of water power.

Calcium carbide, ferro-alloys, sodium, chlorates and phosphorus are in practically the same position as artificial abrasives, all requiring power at the prevailing water-power rates and within close proximity to the center of gravity of their consumption.

Of the ferro-alloys, perhaps ferro-silicon is the most popular just now owing to the high selling price. This price is abnormal, having been brought about by a shortage created by the unprecedented demand for shell steel and armor plate, shell steel requiring some 0.3 per cent silicon, which is a very high percentage compared to the normal run of steel. Furthermore the importation of ferro-silicon from England and Canada has been discontinued and England has even pleaded for some of our ferro-silicon output. Eighty per cent of the ferro-silicon produced in this country comes from the Niagara district, where the power shortage is exceedingly acute and it is practically impossible at the present time to increase this output. Previous to the war, $70 to $75 per ton was considered a fair price for this commodity, it having sold as low as $51, which price incidentally shows no profit whatsoever. Since that time the price has been up above $200 per ton and now is fluctuating between $150 and $175 per ton. This price, of course, is unreasonable, and cannot be expected to remain. Therefore, those who enter into the manufacture of this commodity are treading on rather treacherous ground from an economic standpoint.

From an engineering standpoint, ferro-silicon can be made most economically under normal circumstances in furnaces of about 10,000 horsepower input, and apparently those companies that are now entering this field or contemplate such action are planning on small furnaces. Such engineering cannot withstand the rigors of competition that will follow this war. But, on the other hand, where companies insist on entering this field now to take advantage of the present high prices, limited capital requires the installation of small furnaces.

Another engineering detail in the use of electric power in the manufacture of ferro-silicon has often been overlooked, and it is this particular feature which practically precludes the present day central station from entering this field, though I understand a number of them have been figuring on putting in their off-peak power, particularly their summer valley, into such a load. I am speaking of the question of frequency. As a rule, the central station catering to the lighting load generates at 60 cycles, but 60 cycles almost precludes the operation of a ferro-silicon furnace of any size, the reason being, obviously, that a very poor power factor results from high currents at high frequency. Probably ferro-silicon furnaces of capacities approaching 800 to 1000 horsepower might be built with a result in power factor approaching 90 per cent, relatively larger furnaces would have still lower power factor. This, of course, entails increased cost in the transforming equipment and therefore handicaps you further in the cost of production. Low frequency is a prime requisite to the successful operation of ferro-alloy, calcium carbide and similar furnaces.

United States Government Nitrate plant No. 2 has already encountered a serious difficulty in furnace design for manufacturing carbide, which is a step in the cyanamide process, because of the fact that they have decided on using 60-cycle turbo-generators. How this matter will eventually work out is hard to tell, but ap-

*An address made at the Dayton meeting of the Ohio Electric Light Association. The author represents the General Electric Co. at Niagara Falls.

parently from the engineering done so far, the size of the calcium carbide furnace will have to be materially reduced from the estimated capacity and this, of course, will entail an increased cost of output. Most of the electric furnace products have been developed at Niagara Falls where 25 cycles is the prevailing frequency. Even lower cycles than this are perhaps preferable for electrochemical loads. Consequently the central station at present installed, producing power for domestic and industrial purposes, is handicapped from practically every standpoint.

Impracticability of Off-Peak Power

If we consider off-peak power for such loads as artificial abrasives, ferro-alloys or calcium carbide, we find that an 80 per cent load factor so greatly increases the overhead costs that the power would have to be obtained without any cost at all to be at all attractive. Daily off-peak power for carborundum, for instance, is absolutely out of the question, as a carborundum furnace operates for thirty-six hour periods. Neither can the graphite furnace be considered for the same reason. Here, of course, the operating periods are considerably longer. Valley power covering a period of eight months is an economic possibility that is not attractive to the average electrochemical industry. There are a few electrochemical markets which are seasonable and whose fluctuations correspond fairly well to the valley of the usual public service company. But to produce the average requirements will entail an investment of 50 per cent in excess of the plant operating on a flat load over a year period and would increase the overhead charges to a point where the proposition is not as a rule attractive.

The smallest user of power per ton output is perhaps the caustic and chlorine industry and is consequently the most affected by long freight hauls. We see as a consequence that caustic and chlorine are manufactured near their markets and comprise one of the few electrochemical industries that the central station may hope to attract. But even here we have the unfortunate situation that confronts all electrochemical industries that depend upon power purchased from a public service corporation, that is, a twenty-four hour load undoubtedly penalized from a bookkeeping standpoint in favor of the domestic consumer. This is known to the caustic manufacturers who in the past have obtained power from power companies whose main output is twenty-four hour power and in consequence the steam plant has not been very successful in attracting the load apparently most suitable to this type of service. Apparently this is a matter for the consideration of the rate-making commissions or commissions approving rate-making in the various states. Naturally, such a situation would have to be brought to the attention of the above mentioned commissions by the central stations themselves.

It is true that under prevailing prices of some electrochemicals there may be some central station whose power could be utilized. The shortage particularly in ferro-silicon may be so acute that the Government will commandeer the power in certain large cities just as they have commandeered the complete output of the power companies at Niagara Falls and Buffalo. This necessitates the closing down of non-essential manufacturing plants with the subsequent damages that always accompany such situation, the central station losing not alone its industrial load but also the load of those operatives and employees who, through the fact that they have lost their employment, move from the city. Manufacturing plants (industrial) usually require a large number of operatives per horsepower, whereas an electrochemical industry uses a great many horsepower per operative. Where it is possible these manufacturing industries will move to other communities where power is available.

Readjustment When Peace Comes

When peace comes, as it must in time, be it one year or ten, the electrochemical plants located in cities where the manufacture of their products is uneconomical under normal peace conditions will, of course, fail when competition again becomes keen. It will be those companies located at the present economic positions and possessing water power, which in itself leads to the reduction of costs, whether by virtue of price, quantity or frequency, that will survive this ordeal. The central station may then find itself in the position of having connected load without the ability of their load absorbing its power and it will take a long time to again build up the load to where it was when the war began. Obviously, the only classes of large power users that the modern central station in large cities should solicit are japanning ovens, brass-melting and steel-melting furnaces (where good scrap is available and other conditions correct), as well as hundreds of industrial power-consuming devices now being perfected or which have not as yet become commercially applicable, but will be perfected under the present war stimulus.

It would appear therefore that the various steam-generating companies should use every effort to increase installed capacity of water power for this class of consumer, having in mind the protection of their own interests. Undoubtedly this is true. In the past the steam plant seems to have felt that water power was a competitor of no mean ability, but this is, strictly speaking, not true except in a few minor cases.

In the Niagara district, for instance, the economic situation was vastly improved when the steam plant was installed to take up the daily peaks. We have often been told, but many of us still fail to realize that water power should never be used for loads of short duration. It costs practically no more to generate power for twenty-four hours than for one hour, which is diametrically opposite the steam situation.

Installation Costs of Steam and Water Plants

In the case of the steam plant under normal price conditions, installation costs range around $50 per horsepower with a tendency downward in the future due to new developments in steam-turbine and boiler economics which will be announced to the world after the mad demand for production subsides. On the other hand, an installed horsepower in water-power plants can be safely stated to be about $150 under the same economic conditions. But the future instead of reducing the installation costs as in the case of the steam plant holds nothing for it except increased costs. This is due to the conditions to which water-power rights will be subjected by the present Congress should they eventually realize the necessity of legislation of a nature that will permit of the development of some of the fifty-four million available horsepower in our navigable streams. It is a well known fact that the House of

Representatives in Washington feels that no water-power rights should be granted without monetary consideration to the federal government either in the form of a lease or taxes. Added to this, they have, in all the legislation at present considered, insisted that water-power companies develop the navigable streams with a view of bettering navigation conditions on these particular rivers. This entails heavy expense for locks and headwater improvements which undoubtedly will bring the cost of this class of power to about $200 a horsepower when considered on the basis of prices before the war.

When we consider that we are paying interest on investment for twenty-four hours a day in either steam or water-power developments and our water-power developments cost four times the steam power development, it is easy to see why load factors approaching 100 per cent are essential for water-power plants and that the usual domestic load of four-hour peak tends to the uneconomical use of capital. Considering the steam plant, the major expense is in fuel, which is on a gradually increasing scale owing to the increasing cost of mining coal as well as a slowly but steadily disappearing supply.

When we consider that the year 1917 doubled the installed capacity of steam turbines and that the year 1918, based on orders at hand, will further increase this by 60 per cent of the total installed Jan. 1, 1918, we can readily see what is before us in the way of coal demands which will hardly have a reducing effect on the price of fuel.

Eminent engineers have figured that even with water power at hand, should the load factor be 40 per cent or less, steam power should be used; but should the load factor be 60 per cent and above, water power is the most economical development. The field represented between these two points is subject to local conditions and may or may not be economical water-power or steam-power developments, depending upon other conditions surrounding the particular problem. The only exception to the above would be, of course, a case where the power consumed equalled the total amount of storage available.

Two factors have contributed to the elimination of cheap power; first, the limited development of water power; second, the inability of steam stations to make consistent rates for twenty-four-hour power. This has led to the expatriation of some of our most essential industries. Long ago the only fertilizer industry on this continent, an American company incidentally, went to Canada, where they obtained low power rates. Additions to the Carborundum Company and the Norton Company were built in France and Germany respectively for the same reason. Both of these companies have recently built large plants in Canada. The Union Carbide Company has transferred its carbide production from Niagara Falls, N. Y., to the Canadian side and additions for ferrosilicon in Norway. Lastly, we hear that the Acheson Graphite Company is planning to build at Shawinigan Falls, Que. Thus it is that many of our great industries have gone to other countries in search of cheap power. This may not be serious, but should Canada ever decide to stop exportation of any of these essentials, the United States would find itself in much the same position it was in at the beginning of the war with regard to dyestuffs.

Research Information Committee Formed

THE following statement is authorized by the Council of National Defense:

1. By joint action the Secretaries of War and Navy, with the approval of the Council of National Defense, have authorized and approved the organization, through the National Research Council, of a Research Information Committee in Washington with branch committees in Paris and London, which are intended to work in close co-operation with the officers of the Military and Naval Intelligence, and whose function shall be the securing, classifying and disseminating of scientific, technical and industrial research information, especially relating to war problems, and the interchange of such information between the Allies in Europe and the United States.

The chief functions of the foreign committees thus organized are intended to be as follows:

(a) The development of contact with all important research laboratories or agencies, governmental or private; the compilation of problems and subjects under investigation, and the collection and compilation of the results attained.

(b) The classification, organization and preparation of such information for transmission to the Research Information Committee in Washington.

(c) The maintenance of continuous contact with the work of the offices and military and naval attachés in order that all duplication of work or crossing of effort may be avoided, with the consequent waste of time and energy and the confusion from duplicated effort.

(d) To serve as an immediate auxiliary to the offices of the military and naval attachés in the collection, analysis and compilation of scientific, technical and industrial research information.

(e) To serve as an agency at the immediate service of the commander in chief of the military or naval forces in Europe for the collection and analysis of scientific and technical research information, and as an auxiliary to such direct military and naval agencies as may be in use for the purpose.

(f) To serve as centers of distribution to the American Expeditionary Forces in France and to the American naval forces in European waters of scientific and technical research information, originating in the United States and transmitted through the Research Information Committee in Washington.

(g) To serve as centers of distribution to our allies in Europe of scientific, technical and industrial research information originating in the United States and transmitted through the Research Information Committee in Washington.

(h) The maintenance of the necessary contact between the offices in Paris and London in order that provision may be made for the direct and prompt interchange of scientific and technical information.

(i) To aid research workers or collectors of scientific, technical and industrial information from the United States, when properly accredited from the Research Information Committee in Washington.

The headquarters of the Research Information Committee in Washington is in the offices of the National Research Council, 1023 Sixteenth Street; the branch committees are located at the American Embassies in London and Paris.

The Physical Properties of Copper and the Factors by Which They Are Affected—IV.

By Paul D. Merica
Division of Metallurgy, U. S. Bureau of Standards

(*Concluded from page* 307)

Impurities in Copper; Effect on Physical Properties

OXYGEN

THE constitution of the alloys of copper and oxygen (Cu_2O) shows that oxygen is present in copper as Cu_2O, not dissolved appreciably by the copper (223). There seem to be no published records of test results showing the effect of oxygen on copper free (in the commercial sense) from other impurities. It is, of course, well known that in melting copper it must be brought to pitch in order that it may be cast free from blowholes and possess the best mechanical and "working" properties. If under pitch the presence of blowholes will cause seams in the metal which may open up in drawing; if underpoled the excess oxygen may cause cracking during cold-rolling, and if the oxygen is in amounts as great as the eutectic composition it may also be hot-short.

Hampe (253) found that Cu_2O had no effect on the strength or malleability of pure copper until 0.45 per cent was reached, when a very slight diminution of tenacity was recorded. Ductility in the cold was not affected until 0.9 per cent was reached. Beyond 0.9 per cent the quality of the copper suffered more and more as the proportion of Cu_2O was increased.

Johnson has given some results of tests of oxygen bearing arsenical copper; see Table IX.

The influence of oxygen on copper is chiefly interesting in conjunction with that of other impurities, notably bismuth, antimony, arsenic and lead. It diminishes the embrittling effect of bismuth (Johnson) and lead; this is probably due to two facts: (1) That in the presence of oxygen an oxide of either of these metals is formed which melts at a higher temperature than the metal, and (2) that this oxide is distributed as fine globules instead of thin plates as is the metal.

Greaves (252) has studied the effect of oxygen in copper containing arsenic and antimony, studying the cold-rolling and drawing properties, hardness and microstructure. His conclusions relative to cold-rolling (strips were cold-rolled with annealing from 0.35 to 0.02 in. in thickness) are:

> "As the amount of arsenic increases up to 0.5 per cent the metal may take up more oxygen without suffering deterioration in its capacity for rolling. This quantity of oxygen rises from about 0.05 per cent to 0.2 per cent as the arsenic increases from 0 to 0.2 per cent, then more slowly to about 0.28 per cent as the arsenic rises to 0.5 per cent. . . . When less than 0.3 per cent of O_2 is present, a metal which will roll perfectly is obtained before the arsenic reaches 0.5 per cent.
>
> "In a similar way antimony up to 0.4 per cent reduces the cold-shortness of pure 'dry' copper."

His conclusions relative to wire-drawing tests are that the conditions obtaining are entirely similar to those in rolling copper.

Baucke (Tables IV and X) has some results on the toughness of cast and forged alloys with varying percentages of oxygen.

PHOSPHORUS

The diagram for alloys of copper and phosphorus has been partly established by Heyn and Bauer (224). Phosphorus in the form of Cu_3P is dissolved in copper to the extent of 0.175 per cent. Phosphorus in these small amounts hardens copper, as can be seen from Table VIII of Muenker's (273) results.

SILICON

The alloys of silicon and copper have been studied by Rudolfi (226) and Guertler (227).

Copper with small amounts of silicon (0.02 to 0.10 per cent) is used abroad for telephone wire, electric cables, etc. The electrical conductivity is decreased by about 2 per cent by addition of 0.02 to 0.05 per cent silicon (Guillet).

Apparently in small amounts it does not harden copper appreciably (Vickers 281); the copper cast using silicon as a deoxidizer is often called silicon bronze, although it contains practically no silicon.

SILVER

The constitution of the silver-copper alloys has been studied by Heycock and Neville (228), Lepkowski (230), and others. Copper takes up about 3 per cent of silver in solid solution.

Johnson (261) studied the effect of additions of silver to tough-pitch copper and concludes that up to about 0.2 per cent the tensile strength is increased by about 3 to 5 per cent, the elongation decreased by 10 to 15 per cent, and that "the effect of silver in the proportions ordinarily found . . . is beneficial on the whole as regards mechanical properties and negligible as regards hot-working properties"; see Table IX.

SULPHUR

The constitution of the copper-sulphur alloys has been studied by Heyn and Bauer (231).

The amount of sulphur as Cu_2S taken up by the copper in solid solution is extremely small (< 0.1 per cent).

Opinion seems to be agreed that as little as 0.1 per cent sulphur in copper renders it hot-short (276). No investigation has been made of the effect of sulphur on the mechanical properties at ordinary temperatures.

TIN

The copper-tin equilibrium diagram has been worked out by Heycock and Neville (233), Shepherd and Blough (234), and others. Copper dissolves about 11 per cent of tin, and within these limits it is hardened by the tin addition.

Muenker (273) gives results of mechanical tests on copper-tin alloys; see Table VIII. Baucke finds that tin in small amounts increases the toughness of copper; see Table X. The alloys of tin and copper are called bronzes, and are generally used of compositions from 0 to 25 per cent tin.

TITANIUM

The equilibrium of the alloys of titanium and copper has been studied by Bensel (235) and Rossi (236). Copper dissolves up to 0.32 per cent of titanium. In small proportions this metal raises the tensile strength and lowers the ductility.

TABLE IX—EFFECTS OF BISMUTH, SILVER, AND ALUMINIUM ON THE PROPERTIES OF ARSENICAL "TOUGH-PITCH" COPPER (JOHNSON, 261)

Ingots were made of cathode copper, arsenic and impurity, poled to pitch and cast as 1¼x1¼x6 in. ingots, rolled at bright red heat in S passes to ½-in. rods and quenched.

Some specimens were hammered out flat to ¼ in. thickness cold, then passed through cold rolls set at ¼ in. The specimens were then annealed at dull red heat for ½ hour and quenched in water.

[1]Test piece, 0.75x0.375", placed under hammer and subjected to light blows until cracks appear.

[2]Material falling in classes 1–4 may be rolled at a bright red heat. (The point which determines the classifying of metal between 1 and 4 is the comparative susceptibility to cracking during rolling. Class 5 may be regarded as the critical stage between material fit for rolling at a bright red and material unfit for such treatment, material of this class (5) would better be rolled at a slightly lower temperature. Material in a lower class can be considered unfit for hot rolling.

U = unbroken, b = broken.

ZINC

The zinc-copper equilibrium diagram has been studied by Roberts-Austen (239), Shepherd (240), Tafel (241), and others.

Zinc is dissolved in copper to the extent of about 35 per cent. It hardens copper and first increases, then diminishes its ductility. Curves, Fig. 24, by Webster

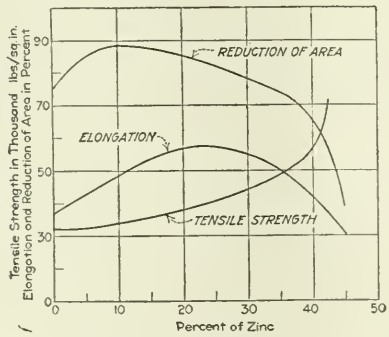

FIG. 24. MECHANICAL PROPERTIES OF ROLLED AND ANNEALED COPPER-ZINC ALLOYS (WEBSTER)

(282) show the mechanical properties of rolled and annealed copper-zinc alloys; i.e., the brasses, made of pure materials.

Baucke finds that zinc in small amounts increases the toughness of copper; see Table X.

GASES IN COPPER

It is generally held that the solubility of gases in solid copper is quite small; in fact, it is to this prop-

[1]Baucke gives S. I. W. in kilos, but it is assumed that he means kilogram-meters.

erty that the "spewing" upon solidification of overpoled copper is due. The molten copper absorbs gas which is given up upon solidification.

Sieverts (284, 285) has determined the solubilities of H_2 and SO_2 in copper. He finds that 100 grams of copper will absorb the following amounts of gas:

Table XI—Absorption of Gas by Copper

Temperature, Deg. C.	H_2, Solubility in Mg. per 100 Grams	SO_2, Solubility in Mg. per 100 Grams
1400	1.2	
1330		706
1220		596
1120		448
1084 (liquid)	0.6	
1084 (solid)	0.2	
400	0.006	

N_2, CO, and CO_2 are not appreciably soluble in solid copper. He finds that for a constant temperature the solubility is proportional to the square root of the pressure of the gas.

Both silver and gold diminish the solubility of SO_2 in molten copper, the former much more markedly than the latter.

Sieverts (284) concludes that dissolved hydrogen has no appreciable effect on the electrical conductivity up to 870 deg. C., but that SO_2 increases the resistivity (part of this change may have been due to interreaction with the porcelain containing tubes).

"Diseases" of Copper

Copper is, relatively speaking, insensitive to thermal variations in conditions and operations of manufacture. After annealing or after forging operations at a bright red heat (900 deg. C.) it may be slowly cooled or quenched in water, the latter method conferring, according to some, even greater ductility and toughness than the slow cooling.

It is possible, however, to overheat and to burn copper. Heyn (289) has shown that maximum toughness (repeated bend test)is obtained by annealing at 500 deg. C., the time of annealing being without effect. Samples of copper which gave 6¾ 90-deg. bends upon such annealing gave only four when annealed for 90 minutes at 1050 deg. C.

Baucke (287) has shown that heating to 700 deg. C. has practically no effect on the toughness as indicated by the Frémont test; in fact, heating in air or CO_2 at 1055 deg. C. for 15 minutes produced only a slight decrease of the specific impact work necessary to fracture from 77 to 101 ft.-lb. (11.6 to 15.1 kgm.).

Copper should be worked at about 900 deg. C. and not above 1000 deg. C., according to Johnson (290). If heated to and worked at temperatures in the neighborhood of the eutectic melting temperature the copper may be burnt, pits form and grain boundaries become oxidized.

When copper is heated to 800 deg. C. and above in an atmosphere of reducing gases, CO, H, etc., the gases permeate into the copper and reduce the Cu_2O; water is formed, as steam under pressure, and produces fine cracks throughout the copper, which is described as "gassed." Such copper is, of course, weak and brittle. A photomicrograph, Fig. X, shows such cracks near the brazed seam of a failed copper bend steam pipe. The brazing operation was improperly conducted, a reducing flame having been played on the copper with the result that cracks were formed near the surface, leading later to failure. Baucke (287) has reduced the toughness of copper as shown by the Frémont test from a specific impact work necessary to fracture of 94 to 101 ft.-lb. (13 to 14 kgm.) to 14.5 ft.-lb. (2 kgm.) by heating the sample for two hours at 800 deg. C. in hydrogen gas.

Matthews and Thalheimer (191) have carried out the most extensive tests to determine the actual effect of annealing in a reducing atmosphere on the strength and ductility of copper. They used coal gas and annealed for 40 minutes strips of from 0.064 to 0.067 in. in thickness at 600 deg., 800 deg. and 1000 deg. C.

Their average results are given in Table XII.

Table XII—Effect of Annealing in Coal Gas on Mechanical Properties of Copper

Time of annealing, 40 minutes.

	Tensile Strength, Lb./Sq. In.	Reduction of Area, per Cent	Elongation, per Cent
Electrolytic copper	33,000	46	54
600 deg. C.	29,000		22
800 deg. C.	19,000	12	11
1000 deg. C.	21,000	12	11
Mohawk copper	33,000	49	55
600 deg. C.	30,000		27
800 deg. C.	18,000		8
1000 deg. C.	21,000	15–18	16
Copper Range copper	33,000	50	57
600 deg. C.	31,000	39	41
800 deg. C.	21,000	12	11
1000 deg. C.	22,000	16	16

The Copper Range copper, containing 0.296 per cent arsenic, undoubtedly resists the action of reducing gases better than do the purer varieties. This is also shown by experiments by Bengough and Hill (247.)

Corrosion of Copper

Copper is exposed to corrosion by water, air, steam, etc., in a variety of commercial forms, pipe, steam fittings, roofing, etc., so that the question of the corrosion of copper under such conditions is an important one. Practically no systematic investigation has been made, however, of the rate of corrosion of different samples of copper under these various conditions.

Carpenter (296) exposed sheets of aluminium, copper, iron and other metals to corrosion on the roof of an office building, in a railway tunnel, and in smokestack plates, and observed the rate of corrosion expressed in loss of thickness per surface inch per year. His results follow:

Table XIII—Corrosion Loss

	On Office Building, Inches	In Railway Tunnel, Inches	In Smokestack Plates, Inches
Copper (plain)	0.0000	0.004	0.014
Aluminium	0.0011	0.013	
Iron	0.001 to 0.004	0.15	0.018
Steel		0.12	0.020

The copper samples tested were from 99.53 to 99.76 per cent pure. The corrosion was quite uniform in the case of the copper and is seen to be less than that of the other materials.

Corrosion of copper may be quite uniform, a covering and protecting layer of oxide or green basic carbonate or, in marine atmospheres, of oxychloride, being formed. Often, however, the attack is quite local, with formation of pits and furrows. Such pits are mentioned by Corner (297), Merica (299), and others; they are to be attributed to local electrolytic action

caused by the presence near the pit of a substance electronegative to the copper. It is probable that copper oxide and even some of the basic oxidation products of copper may serve as such electronegative "poles."

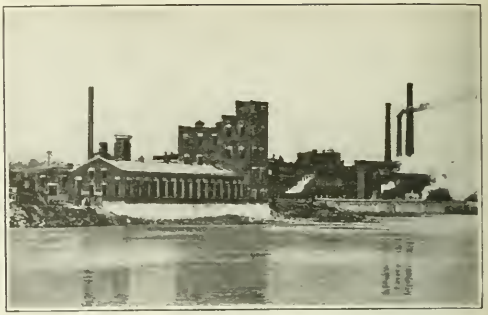
It has been shown by Rhead also (301) that hard copper is more readily corrodible than soft copper, the rate of corrosion of the former having been 0 to 500 per cent greater than that of the latter in his experiments. Eastick (298) also holds that the presence of hard and soft areas in copper are often responsible for local corrosion.

Alcohol from Sulphite-Pulp Waste Liquor

Plant of the West Virginia Pulp & Paper Co. at Mechanicville, N. Y.

By Ellwood Hendrick

"THERE'S a good deal o' miscellaneous eatin' to a sheep," said a Scotchman, and anyone who has ever tasted haggis will confirm the statement. Likewise any chemist who has had to do with sulphite-pulp waste liquor is apt to find a similar disposition within his soul and to declare that there is a good deal of miscellaneous chemistry in it. The liquor contains from 8 per cent to 10 per cent of dry residue, which includes the lignin, with all that the word implies. Less than one and a half per cent of the dry residue is inorganic. In varying quantities there is SO_2 both free and combined, sulphuric acid and about three-quarters of 1 per cent of lime. The sugar content varies from a maximum of 3 per cent to something pretty close to zero as the minimum. One per cent of alcohol from the liquor is a very high yield, even in Sweden. With good practice about two-thirds of the sugar is fermentable.



WEST VIRGINIA PULP AND PAPER MILL, MECHANICVILLE, N. Y.

In 1913 the West Virginia Pulp & Paper Company put up the first plant in the United States at Mechanicville, N. Y., to make ethyl alcohol from this material. Operations began in March, 1914. Counting all the costs, it has not been a profitable undertaking. But where should we be if there were nobody to try things out? The feeble of will are discouraged by unsuccessful experiments, and such men lead only at industrial funerals. The real leaders in industry, on the other hand, have the virtue of perseverance along with the quality of sportsmanship, and often, indeed, they can see romance in a scrap-heap that wrings only tears of gloom from their ungifted fellows.

FIG. 1. ALCOHOL STILL, W. VA. PULP & PAPER CO., MECHANICVILLE, N. Y.

The alcohol plant was built to treat 100,000 gallons of waste liquor a day, which at that time was the regular product of the establishment at Mechanicville. They have been producing 500 gallons of alcohol per day. This is now running somewhat higher owing to changes in methods.

Whether any of the sugar found in the liquor is that which was formed of water and CO_2 by the catalytic action of chlorophyll in the green leaves of the trees while still growing seems still open to question, although it is hardly possible that more than a very small portion of it, if any, can come from this source. Dr. Erik Haegglund, in

an interesting series of articles,[1] claims that wet wood produces more sugar than that which is dry. This has not been confirmed at Mechanicville. He also expresses the opinion that none of the sugar present has its origin in cellulose, although he says that Dr. Eckstrom, under whose patents these works are operated, holds the opposite view. The impression prevails also that a good part of the sugar is the product of lignin; from all of which we may gather that the chemical history of the sugar in sulphite waste liquors is still more or less guessed at.

The presence of fermentable sugars is in part dependent upon the cooking. A high content of free SO tends to increase the sugar in the waste liquor and to shorten the time of the cook. There are also other reasons for the disposition of pulp makers to increase the free SO in their digesters. So we may set down as a rule that if the free SO_2 in the digesters is inadequate, the sugar will be deficient; and we even venture the assertion that the more free SO_2 there is in the digesters, the more sugar will be produced. But we must immediately qualify this statement, because as soon as the SO_2 concentration gets too high, the sugars are decomposed. Indeed, an excess of free SO_2 will destroy the sugar before the cook is completed. Fermentable sugars are more easily decomposed in this manner than the pentoses (xylose). Too high a temperature alone will also destroy the sugar in the digesters. The good feature of the situation is that with the speed of the cook increased by the SO_2 concentration, it is possible so to regulate the process that it is brought to a conclusion at the point where the maximum sugar is obtained. It is not difficult to do this on the one hand, and it is not a rule-of-thumb operation on the other.

From the pulp mill the liquor is run into a great tank. Then the first step in making alcohol from it is to pump it into the neutralizing towers, which have a working capacity of about 40,000 gallons each. This is also a process involving a lot of miscellaneous chemistry. One one-hundredth of 1 per cent of sulphurous acid will kill yeast in 24 hours. Sugar is broken up as soon as a state of alkalinity is reached. Lime in solution is carried over and clogs the still columns and dephlegmator tubes; it takes an interminable time to settle, and fermentation demands a clear liquid. Calcium carbonate produces gypsum, which may leave a clear solution at first, but as it approaches the boiling point a precipitation of extremely small crystals of gypsum takes place. The usual method is to split the troubles by adding the proper quantity of slaked lime at first and half an hour afterwards some pulverized limestone. At Mechanicville lime sludge from the soda pulp mill is employed, which is acknowledged to be the best practice, provided the soda pulp mill is handy.

When the liquor and lime sludge are led into the neutralizing tanks, agitation is accomplished by the introduction of compressed air at the bottom. This is continued for three hours, after which it is allowed to settle for 11 hours; then the clarified liquor is decanted and the sludge, which is now gypsum, is discarded. But the liquor is not yet clear enough, lime and gypsum are still in suspension, and it is still warm. It is therefore run into so-called neutral lye bins which are long and shallow, where it settles for from 10 to 12 hours more. It is now clear enough to go on with the fermentation, but it is not yet cool enough, so from the neutral lye bins it is pumped into a very simple cooling tower. This is constructed with a receiving tank having a perforated bottom at the top of the tower. From the perforated bottom there extend downward for several feet a series of board partitions, several inches apart, which serve as a trickling device. From these the liquor falls down in the form of a very lively rain. Halfway down the drops meet a blast of air from a blower, which blows the liquor pretty well over to one side of the tower, but it is all collected at the bottom in another tank. It is a remarkably effective cooling system.

From the tank at the bottom of the tower the liquor flows by gravity into the fermenting vats. These are

FIG. 2. FERMENTING VATS, W. VA. PULP & PAPER CO., MECHANICVILLE, N. Y.

[1] Published in *Paper*, December, 1917, and January, 1918, Vol. XXI, Nos. 15 to 20.

of concrete, circular in form and hold about 35,000 gallons each. The yeast and its proper food is already in the fermenting vats into which the cooled liquor now enters through three vents, so arranged as to give a circular motion to the entering liquor and thoroughly mixing it with the yeast. By means of this agitation the fermenting begins within about twelve hours. If the liquor is poured into the vat at the top without other agitation, it does not begin to ferment until about 48 hours has elapsed.

The yeast was brought over from Sweden by Dr. Eckstrom, who designed the plant. Dr. Haegglund found types XII and M, distillery yeasts of the Berlin Institute of Fermentation Industry, to be peculiarly suitable.[2] Dr. Drewsen of the West Virginia Pulp & Paper Company made certain researches in the matter and found other yeasts also available. Dr. Eckstrom's yeast, however, is still in use, although, owing to the nature of the liquor and its chemical miscellaneousness, the spent yeast is not reclaimed. To support its growth, spent brewers' yeast is submitted to "autodigestion" by heating it to 40 to 50 deg. C. under pressure. The protein substances are thus digested by the enzyme endotryptose with the consequent formation of amides.

Dr. Haegglund reports that Sweden produces 660,000 gallons of alcohol annually by this method. He also computes that inasmuch as Germany produces 550,000 metric tons of pulp per year, they must be making 5,284,000 gallons of alcohol out of their waste liquors. But statistics based upon what the Germans are probably doing just at this time are not wholly persuasive to us. A computation as to their scraps of paper would carry greater conviction.

We desire to express our sincere obligations to the officers and staff of the West Virginia Pulp & Paper Company, for their courtesy in permitting us to publish the above details of their work and their industrial adventure in this interesting field.

Japan's Electrochemical Industry.—The electrochemical industry of Japan has made enormous strides during the past three years, according to *Denkinotomo*, the Japanese electrical semi-monthly magazine. At the beginning of the war it was one of the minor industries of the country, being grouped with the allied industries. In 1915 it was separately reported, its product being valued at 61,600,000 yen. In 1916 it increased to 117,727,211 yen, while for 1917 indications point to a 300,000,000 yen ($150,000,000) output. The official returns for the past year have not yet been completed.

Splitting Limits in Colorado.—The customary splitting limits as usually agreed upon in ore buying contracts in Colorado are as follows:

Gold	0.02 of an ounce
Silver	0.50 of an ounce
Copper	0.50 per cent
Lead	0.50 per cent

Sulphur	1.00 per cent

[2]Loc. cit.

Simple Washing in the Filter-Press

By D. R. Sperry

TO WASH in a filter-press means to cause a liquid, usually water, to pass through the solids contained in the chambers, displacing from the voids therein some liquid which is not desired in the cake. Washing may also be employed for the purpose of dissolving some solid substance from the cake which may later be recovered from the wash-water. Instead of water, other liquids may be used with which to displace the liquid in the cake or to dissolve some portion of the solids in the cake. Thus it can be seen that washing, lixiviation or extraction may be carried on in the filter-press without removing the solids from the chambers. Indeed the above functions may be performed upon the solids in a filter-press by merely operating the proper valves. If desired, the wash-water can enter the filter-press by a separate channel and leave by a separate channel, so that the connections for the wash-water entrance and for the wash-water exit may be made permanent.

Kinds of Washing

There are two separate and distinct kinds of washing employed in the filter-press, namely, simple washing and thorough washing. The first is not necessarily less

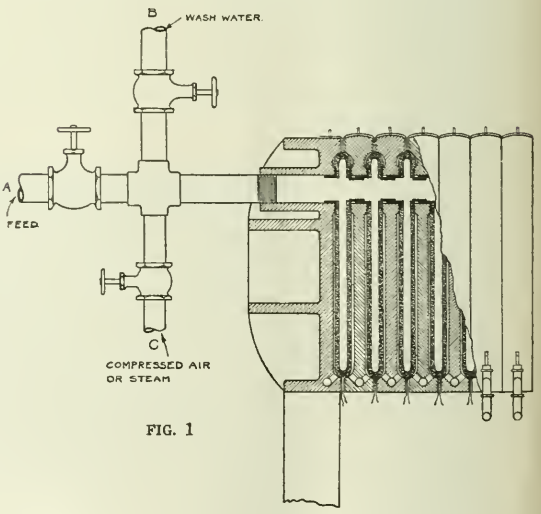

FIG. 1

thorough than the second, but it is much simpler in operation and can be used only in special cases to advantage. This kind of washing is used in the so-called self-dumping filters only because it is impossible to use thorough washing in that kind of filter. Selection of which of the two types of washing should be used in the filter-press depends upon the character of solids in the substance to be filtered and upon its chemical nature as regards acidity or alkalinity. The kind of filter-base used may also be a controlling factor as to whether simple or thorough washing is the most suitable to use.

Simple Washing

In simple washing the filling of the chambers of a filter-press must stop before the solids forming on

the filter-base have met each other. In other words, filling of the filter-press must stop while there is still an unfilled space down the center of the chamber. A filter-press which has reached this point of filling is shown in cross-section in Fig. 1. When this stage is reached the material which is being fed into the filter-press is closed off, as would be done if valve *A* were closed, and valve *B* running to wash-water supply opened. The pressure of the wash-water should be equal to or greater than that used in filling the filter-press. Under these conditions the wash-water soon displaces the mixture remaining in the unfilled space and itself passes through the deposited solids, against the plate surface and out through the cocks the same as the filtrate did during the filling process. The washing process is allowed to continue until the issuing wash-water indicates by its physical or chemical characteristics that the desired effect upon the solids has been reached. The wash-water is then closed off, and frequently compressed air is admitted into the filter-press as would be done by closing valve *B* and opening valve *C*. The effect of the air is to displace the wash-water remaining in the center of the cake as well as a certain amount of that held by the cake itself. In other cases steam instead of air may be admitted through valve *C*, this having the effect of displacing the wash-water and also of drying the cake to a certain extent.

Simple Washing with Separate Connections

In the case of simple washing just described it will be noted that no change whatever in the internal arrangement of the filter-press was necessary, the wash-water, air, or steam entering the chambers along the same path used by the material to be filtered. The wash-water thus issues from the filter-press cocks and into the gutter. It frequently happens that it is not

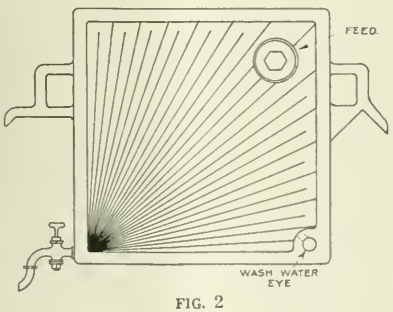

FIG. 2

desirable to have the wash-water or solvent leave the filter-press via the cocks and gutter. In that case a separate outlet for the wash may be arranged.

This is brought about by placing an eye usually in the lower corner of the plate opposite the cock. This eye has a port which connects it with the surface of the plate. A plate of the recessed type having a separate outlet for wash is shown in Fig. 2. When plates with a wash-outlet eye as shown are placed in a filter-press, the wash eyes register with each other, forming a continuous channel from one end of the filter-press to the other, one end of the channel being formed by the movable head, the other by an inlet placed on the fixed head. Due to the ports which connect the eyes with the plate surfaces, the wash channel connects, as it were, all of the plate surfaces in parallel. The wash channel is of course separate and distinct from the feed channel.

In Fig. 3 a cross-section is shown through a filter-press arranged for simple washing with separate outlet for wash. Two sections are shown, the upper one is taken through the feed-inlet and the cock-outlet, while the lower one passes through the center of the plate and the wash-outlet channel. A study of the upper

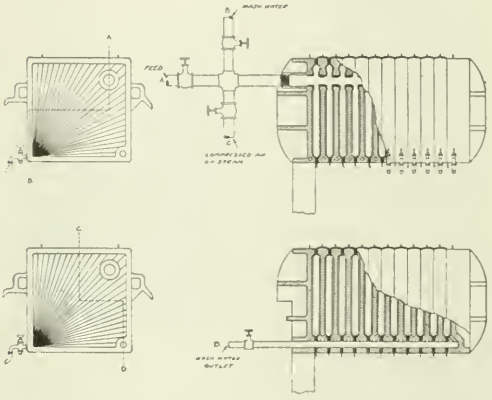

FIG. 3

cross-section shows that the material fed into the filter-press through the inlet located in the fixed head traverses the entire length of the filter-press by means of the openings through the grommets, thus filling all of the chambers formed by the recesses in the plates. During the feeding operation the valves *B*, *C* and *D* are closed while *A*, of course, is open. The material to be filtered is pumped or otherwise forced into the filter-press. As the chambers formed by the recesses in the plates are bounded by canvas or some other filter-base, the solids are caught on it while the liquid passes through filter-base and deposited solids, issuing from the back side of the filter-base and against the surface of the plates. The liquid reaching the surface of the plate is conveyed by means of grooves directly to a lower corner of the plate and out of the filter-press by way of a cock placed at the corner to which the grooves lead.

The filling process, as the depositing of the solids is called, is allowed to continue until a layer of solids is formed on the sides of the chamber of such a thickness that the chamber is not filled solid but an open space left in the center of the chamber. In other words, the solids on opposite sides of the chamber are not allowed to build up until they touch each other, but the process is stopped while there is yet a space between them. At this point it is well to note that if thorough washing, instead of simple washing, were to be employed, the chambers would be allowed to completely fill, instead of only partly fill as in the case considered. When filling has progressed to the proper point, valve *A* is closed, valve *D* opened, valve *B* opened and all of the cocks closed. When this is done the wash-water flows to all the open spaces purposely left down the center of each chamber, following the same route as that previously

taken by the material to be filtered. The wash-water soon displaces the material to be filtered which occupied the open places in the chambers, and itself passes through the deposited solids. As it issues on the back side of the filter-base it flows down the grooves on the plate surface, and, since the cocks are all closed, must flow into the wash channel formed by the eyes in the lower corner of the plate, as shown in cross-section in the lower part of Fig. 3. The pipe connected to the filter-press head at *D* conveys the issuing wash-water to any desired point.

The washing process is allowed to continue until the desired substance has been dissolved or displaced from the solids through which it flows. Chemical or physical tests of the issuing wash-water indicates when the process has continued long enough. When washing is finished valve *B* is closed and the filter-press may be opened ready for another cycle. If, however, it is desired to displace a large portion of the wash-water, valve *C* is opened, thus admitting compressed air or steam. This is allowed to continue until very little wash-water issues from the filter-press, at which point valve *C* is closed. It should be noted that if desired valve *D* may be closed and the cocks opened in order to allow the air or steam to discharge into the gutter.

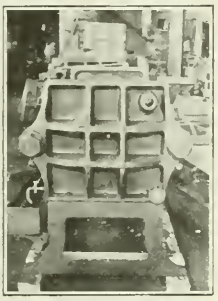

FIG. 4

In Fig. 4 a view is shown of a filter-press arranged for simple washing with separate outlet for wash. The inlet is shown in the upper corner, while the outlet for wash-water can be seen in one of the lower corners. The connections for feed, wash-water, air or steam, and wash-outlet can be seen. The cocks and gutter which carry off the filtrate can be observed along one side of the apparatus.

It can readily be understood that if desired, frames can be placed between the recessed plates, forming a wider chamber. In the lower corner of the frame, corresponding to that in which the wash-water outlet-eye is placed on the plates, an eye must be placed in order to preserve the continuity of the wash-water outlet channel. In Fig. 5 is shown a few plates in cross-section having frames between them. Two cross-sections are given; one, the upper, through the feed-inlet and cock-outlet, the other, the lower, through the center of the plate and the wash-water outlet channel. A picture of the frame is shown in Fig. 6.

New Officers of the Engineering Council

At the first annual meeting of the Engineering Council, on Feb. 21, J. Parke Channing was elected chairman, Harold W. Buck first vice-chairman, George F. Swain second vice-chairman and Alfred D. Flinn secretary. The following committees were appointed:

Executive committee: The Chairman, the two vice-chairmen, and David S. Jacobus, Calvert Townley, George J. Foran.

Finance committee: E. Wilbur Rice, Jr., chairman; Charles F. Loweth, Sidney J. Jennings, David S. Jacobus.

Rules committee: J. Parke Channing, chairman; Clemens Herschel, Nathaniel A. Carle, Irving E. Moultrop.

Public affairs committee: Charles Whiting Baker, chairman; George F. Swan, Benjamin B. Thayer, E. W. Rice, Jr., Charles E. Skinner.

American engineering service: George J. Foran, chairman; George C. Stone, Alfred D. Flinn, Dr. Addams S. McAllister, Edward B. Sturgis, secretary.

War committee of technical societies: D. W. Brunton, chairman; Arthur H. Storrs, secretary; James M. Boyle, Nelson P. Lewis (American Society of Civil Engineers), Edmund B. Kirby (American Institute of Mining Engineers), A. A. Greene, Jr., R. N. Inglis (American Society of Mechanical Engineers), Harold W. Buck, Dr. Addams S. McAllister (American Institute of Electrical Engineers), Dana D. Barnum, E. C. Uhlig (American Gas Institute), Joseph Bijur, Dr. Charles A. Doremus (American Electrochemical Society), Louis B. Marks, Preston S. Millar (Illuminating Engineering Society), Christopher R. Corning, George C. Stone (Mining and Metallurgical Society of America), Henry Torrance, F. E. Matthews (American Society of Refrigerating Engineers).

Report of Smelter and Ore-Sales Investigation Committee, State of Colorado, 1917

IN RESPONSE to a popular demand which has been rather insistent in some parts of Colorado for several years, the General Assembly in 1917 authorized the appointment of a Smelter and Ore Sales Investigation Committee to inquire into the buying, selling and treatment of ores and concentrates in Colorado, and to make such recommendations regarding charges or schedules as might be appropriate. The committee comprised two members of the State Senate and three of the House of Representatives, and the sum of $15,000 was appropriated for their use. Mr. O. R. Whitaker, a consulting engineer of Denver, was employed by the committee to make a technical investigation and report.

Hearings were held in Georgetown, Idaho Springs and Central City, where a number of witnesses appeared. The testimony was, for the most part, a repetition of the same statements, and the hearings were discontinued.

Typical Testimony at Hearings

Mr. A. E. Simpson of Georgetown presented testimony which is typical of the attitude of the small ore-producer. He found no objection with sampling methods nor with the accuracy of the financial returns. His main objection was that the schedules are designed to mystify the ordinary miner, are quite arbitrary in their provisions, and do not return to the producer fair proportion of the metal value of the ores. The latter objection, *i.e.*, that the schedules are not high enough, has lost some of its force because new schedules were issued about the time the investigation started, wherein the miner is paid 75 per cent of the market increase, over the base rate for lead, rather than 50 per cent as formerly. Mr. Simpson was of the opinion that, although returns in recent years were greater due to increased market value of metals, they were not in proportion to the increased cost of ore production.

Mr. Fred S. Caldwell, general manager for the C. H. W. Mining Co., of Central City, stated the manager's position. He said that the committee was charged with determining the answers to the following questions:

(1) What does it cost to smelt the different ores of the various mining districts of Colorado?

(2) What are the actual losses on the different metals during the smelting of their ores?

(3) What is the actual cost of refining base lead bullion and copper matte containing gold and silver?

(4) What are the losses on metal content in the refining of base lead bullion and copper matte containing gold and silver?

Mr. Caldwell exhibited settlement sheets on 41 lots of ore shipped during 1916, which have been summarized in Table I.

In explanation of this table, "Metal Content Less Deductions for Loss in Smelting" represents the sum of the dry weights multiplied by the assay. The analysis of the lead and copper is reduced by 1½ per cent (1 per cent since Sept. 1, 1916, according to the new schedule), which deduction is explained by the ore purchaser as covering the loss in smelting. It is supposed that it requires 90 days to smelt, refine and market the metal; consequently the second column represents the value of the metal 90 days after it was accepted by the smelter. "Returns to Miner" represents the amount paid by the smelter less the treatment charges and freight. The "Gross Margin," therefore, represents the gross profit accruing on these shipments. The unit "Refinery Charges" were taken from *Technical Paper* 83, Bureau of Mines, by C. H. Fulton, and the gold and silver purification estimated at 0.09 cents per pound of lead. "Net Margin" represents the smelters' profit above the profit on the treatment charge, and the refiners' outfit, *i.e.*, an investment of $43,446.33 pays $7,069.63 in 90 days, which is at the rate of 65 per cent per anum.

Table I.—Summary of 41 Lots Shipped by the C. H. W. Mining Co.

Metal Content Less Deductions for Loss in Smelting	Market Value 90 Days from Sale		Returns to Miner		Gross Margin	Refinery Charges Plus Freight on Metal		Net Margin
	Total	Average	Total	Average		Rate	Am't	
Au 1,386.14 oz.	$28,651 36	$20 67	$27,002 33	$19 48	$1649 03	.....	$151 37	$1846 94
Ag 9,791.28 oz.	7,070 18	$0 722	6,720.90	0 686	349 28	..		
Pb 168,181.5 lb.	12,744.34	7.58c	6,432.19	3 82c	6312.15	1.01c lb	1698 63	4613 52
Cu 14,163.8 lb.	4,126.70	29 13c	3,290 91	23 23c	835.79	1.6c lb.	226.62	609 17
Total ..	$52,592 58		$43,446 33		$9146 25		$2076 62	$7069 63

Mr. Caldwell submitted that if this analysis is not correct, and the indicated profit is too high, it is because (a) the treatment charge assessed by the smelter is too low, (b) the deductions for metal loss in smelting are too small, (c) the refining cost is too low, or (d) there exist large refining losses which are not included. He also expressed the opinion that the producer should have the option of receiving metal in return for his ore, after paying a proper treatment charge; this would avoid the necessity of heavy charges assessed by the smelters supposedly to protect themselves against violent market fluctuations.

Mr. Robert H. Sayre, mining engineer of Central City, presented the views of the Gilpin County Mining Association. He compared contracts offered by the U. S. Smelting Co. in Utah with the schedules of the American Smelting & Refining Co. in Colorado, in which the former appeared much more reasonable. For instance, the Utah smelter pays for gold if above 0.02 ounce, against 0.05 ounce in Colorado. Copper deduction for smelting losses is 0.6 per cent in Utah and 1.5 per cent in Colorado, while the price deduction is 2½ cents below quotation, against 6 cents.

Report of Committee's Engineer

The results of the technical investigation made by Mr. O. R. Whitaker are given in the form of typical

schedules, together with an analysis of the cost of ore treatment in Colorado. His report covers operations during a period of five years from January, 1912, to December, 1916, inclusive, and deals with ores containing gold, silver, copper, lead and zinc in commercial quantities. In figuring plant depreciation, he assumed that the life of the plant is 10 years, and a charge of 10 per cent on plant valuation is made to cover this item. Interest charges are figured at 5 per cent per annum. Average annual metal prices are used in computing metal values for the period under review. A summary is given in Table II.

Ore Buying and Selling

The buying and selling of ores and metallurgical products, like any other industry, has but one object in view, that is to show a profit on the business done. It is a commercial transaction in which each party uses the knowledge he has in the protection of his interests.

The mills and smelters have always a clear knowledge of the results of their operations, such as cost of production, treatment, recovery, losses and the price of the product, from which they figure how much will be made on each ore purchase. The producers and sellers of the ores are possibly not so familiar with the details of the treatment processes used, therefore a clear explanation of the contract would be of great assistance to them.

Table II—Summary of Operation of Colorado Ore-Treatment Plants

	Colorado Ores Treated in Custom Mills 1912-1916, Incl.	Colorado Ores Treated in Concentrating and Separating Plants, 1912-1916 Incl.	Colorado Ores Smelted to Colorado Zinc Plants, 1912-1916 Incl. Zn	.....	16.0	35.5	.....	.....	.....

(a) Includes $1.94 for residue treatment.

Since the reduction plants, such as mills and smelters, are built solely for the business of ore treatment, the expense of their operation must necessarily come from the realization of the metal values extracted from the ores treated. It is necessary, therefore, for the companies when purchasing ores to charge the producers with the total cost of treatment, metal losses, refining, marketing, depreciation and interest in addition to their own profits. In determining the ultimate profits on the business, the time between the settlement for the ores to the producer and the realization on the product is very important. Where large stocks of ores are carried at the plant and the amount of refined or semi-refined product in transit is large, sudden variations in the market price of the metals have a decided effect on the increase or decrease of the profits.

In times of high metal prices, ore production is stimulated and stocks are consequently increased. With a low metal market the reverse is true. Also, except under abnormal conditions, the market declines more rapidly than it rises. Therefore, unless some provision is made for the protection of the purchaser of ores carrying metals which fluctuate in price, a loss is more likely to occur than a gain.

Ores are purchased in the open market as offered at the terms agreed upon, and usually without obligation on the part of the producer as to quantity. Time contracts are often made with producers when special ingredients are supplied or a definite tonnage of ore assured.

With a treatment plant operating in, or tributary to a substantial ore supply, it would be impossible to settle for and treat the ores from the various mines immediately on the date of receiving them. Therefore it is necessary to settle on some agreed basis.

No metallurgical process recovers all the metal values from the ores. Therefore the payment for the full metal content at market prices cannot be expected. Deductions are made for treatment, losses, marketing, etc., and paying bonuses where required, making necessary some form of ore selling contract.

The existing ore schedules are the result of a gradual evolution of the ore purchasing business, and in some form or other take into account, by direct treatment, charges or metal deductions, the items of principal importance to the purchaser. Inasmuch as these schedules are drawn to cover, in one contract, the business of paying for the values in the ore, the treatment, the losses in the treatment, the refining and selling of the recovered products, the bonuses and penalties and a protection to the purchaser from loss due to sudden market fluctuations, they are complex. In their use for calculating the value of an ore to a plant, a system of discounts and charges is necessary.

Typical Mill and Smelter Schedules

Custom Cyanide Mill Schedules

The following is a representative schedule for Cripple Creek gold ores treated in custom mills and smelters, prices f.o.b. district, gold at $20.00 per ounce:

Custom Concentrating Mill Schedule

Value up to	$10.00 per ton,	$4.00 per ton freight and treatment
From $10.00 to	$15.00 per ton,	5.00 per ton freight and treatment
From 15.00 to	20.00 per ton,	6.00 per ton freight and treatment
From 20.00 to	25.00 per ton,	6.25 per ton freight and treatment
From 25.00 to	30.00 per ton,	6.50 per ton freight and treatment
From 30.00 to	40.00 per ton,	7.00 per ton freight and treatment
Over	40.00 per ton,	8.00 per ton freight and treatment

Schedules for the purchase of ores to be treated in concentrating and separating plants are complex in that they are used to calculate the price to be paid for ores containing several metals. These schedules usually start with a *base price*, for ores of a certain metal con-

tent at a fixed market price and stated delivery. Unit variations are added or deducted according to the grade of the ore and market variations are also allowed and figured on the market price of the metals affected and are calculated from a stated quotation given in the contract. The gold and silver are usually paid for at a certain price per ounce within specified limits.

There is usually no direct treatment charge made in the purchase of these ores. The cost of treatment, metal losses, etc., together with the profit, is made up from deductions from the various metals contained.

A representative schedule on a zinc-lead-iron sulphide ore is as follows:

Base price per ton, f.o.b. Denver, $6.15

Normal analysis: Zn 25 per cent
Ag 5 oz.
Pb (wet) 5 per cent
Insoluble 7%

Normal metal price, Zinc 5.5c. per lb. St. Louis quotation
Lead 5.5c. per lb. New York quotation

Unit variations:

Penalty for insoluble: 5c. for each per cent above 7.

Zinc: ± 43c. for each per cent above or below 25 per cent

Lead: ± 40c. for each per cent above or below 5 per cent

Silver: ± 30c. for each ounce above or below 5 per cent

Market variation:

Zinc: 7c. per unit (20 lb.) for each $1.00 change in spelter quotation from $5.50 to $7.00. 3½c. per unit from $7.00 to $13.00 maximum.

Lead: 7c. per unit for each $1.00 change in lead quotation from $4.50 to $11.00 maximum.

Gold: $8.00 per oz. from 0.04 oz. to 0.10 oz.
10.00 per oz. from 0.11 oz. to 0.20 oz.
12.00 per oz. from 0.21 oz. to 0.30 oz.
14.00 per oz. over 0.30 oz.

ZINC SMELTER SCHEDULE

Schedules for the purchase of zinc ores are made up from a base price, at a given market for ores of a specified grade. Unit and market variations are according to grade and metal quotations. The deductions made provide for the treatment, metal losses and profit to the smelter. For the operations of the Colorado zinc plants ores containing gold and silver are preferable, and a schedule similar to that used by the concentrating plants would be more preferable than the following:

Representative Schedules for Zinc Ores

F.o.b. Missouri river points. Based on 5c spelter market.

Oxidized		Sulphides
25 to 45	Metal content, % Zn.	38 to 50
25%	Minimum metal content, % Zn.	38%
$21.00 for 40% Zn	Base price, per ton of ore.	$26.95 for 50% Zn
$1.00	Unit variation, up or down.	$1.00
	Market variation:—	
60% of value	Market from $5.00 to $6.00 per 100 lbs.	75% of value
+50% of value	Market from $6.00 to $15.00 per 100 lbs.	+50% of value
+40% of value	Market above $15.00 per 100 lbs.	+50% of value

COPPER-LEAD SMELTER SCHEDULE

Schedules for the purchase of copper-lead ore are usually complex. In order to cover its expense, the smelter usually pays for a percentage of the actual contents of the ore at a price below the market quotation.

For gold in ores, no payment is made for gold of 0.03 oz. or lower, and in some cases if less than 0.05 oz. is present. Also, a price of $19.00 to $19.50 per ounce is paid for the gold, as compared to the actual value of $20.67, which two deductions are intended to cover losses in smelting, marketing, etc.

Ninety-five per cent of the silver content in ores is usually made; likewise no payment is made if the content is less than 1 or 2 oz. per ton.

For copper, a deduction of from 1.0 to 1.5 per cent is made at the quotation, less 3 to 6 cents per pound, depending upon the grade of the ore. Furnace practice in treating copper ores in lead smelters shows an average loss of 5 to 6 lb. of copper per ton of ore treated. The customary deduction of 1.5 units for loss is an arbitrary one and is governed by the quantity of copper ores received by the smelter during a definite period. Since copper is not contained in all ores received by the lead smelters, slag absorption will cause loss continuously, which must be provided for.

Payment for the lead in ores may be made by deducting from 1.0 to 2.0 per cent for the wet analysis to arrive at the so-called "dry-assay," and the balance computed from the current quotation, which is generally figured from the New York sales price of the American Smelting & Refining Company on the date of settlement. In case this sales price, or "quotation," is $4.00 per 100 lb. or less, the seller of the ore received 90 per cent of the quotation for the lead in his ore shown by the dry assay. Should the quotation be over $4.00 per 100 lb., the seller of the ore also receives one-half (or three-quarters in some instances) of the excess. The excess deduction is designed to be a protection for the purchaser against sudden market fluctuations.

In case the settlement is made under the "Unit and Quotation" system, a base price per unit (B) is given in the schedule which varies with the lead-content of the ore. This base is on the supposition that the quotation for lead is $4.00 per 100 lb., and for Clear Creek, Gilpin and Boulder districts is as shown in Table III.

TABLE III

Dry Lead, Per Cent	Base Price per Unit, Cents
5 to 10 incl.	40
Over 10 to 15	43
Over 15 to 20	45
Over 20 to 25	47
Over 25 to 30	49
Over 30 to 35	51
Over 35 to 40	52
Over 40 to 45	52
Over 45 to 50	53
Over 50 to 55	54
Over 55	55

In case the quotation (Q) is more than $4.00, the price paid per unit is figured from the following formula:

$$\text{Price} = B + \frac{\$3.60 + \frac{1}{2}(Q - \$4.00) - \$4.00}{5}$$

In case the quotation (Q) is less than $4.00, the price is figured as

$$\text{Price} = B - \frac{\$4.00 - (Q \times 90 \text{ per cent})}{5}$$

From a large number of schedules given in Mr. Whitaker's report, those in Table IV are representative.

The non-payment for the metals below a certain limit is intended to cover losses and give a commercial protection to the smelters. When these ores are smelted with ores carrying enough of the metals to take care of their proportion of the slag absorption and other losses, then all the excess above this is recovered.

In ores containing under 5% per cent lead, the lead is sometimes paid for as iron at 15c. per unit, but usually nothing is paid. In smelting this ore together with sufficient high-grade ore to bring the lead on the charge high enough for furnace requirements, all of the lead in excess of 30 lb. per ton would be recovered, according to general practice. The commercial reason for this deduction is that the lead content is below smelting requirements, and this ore can only be treated to advantage along with a higher grade lead ore. The limited supply of high grade lead ores therefore controls the smelting capacity on low-grade lead ores. These low-grade ores are not profitable to the smelter for their lead content when considered by themselves, as they can only be smelted by recharging bullion into the furnace, to bring up the lead on the charge, thereby increasing losses and costs.

TABLE IV—SCHEDULES OF ORES AND CONCENTRATES TO LEAD-COPPER SMELTERS, FROM CLEAR CREEK, GILPIN & BOULDER DISTRICTS, COLORADO

Rates f.o.b. cars Denver. Minimum shipment, 1 car-load.

	General Schedule, All Classes Ores and Concentrates	Dry Concentrates	Special Schedule, Lead Ores and Concentrates	Lead Concentrates
Gold, per oz., 0.05 oz. to 2.00 oz	$19 00	$19.00	$19 50	$19 00
Gold, per oz., 2.00 oz. and over	19 50	19 50	19 50	
Silver, if 2 oz. or over	95% N. Y. quotation	95% N. Y. quotation	95% N. Y. quotation	95% N. Y. quotation
Dry copper = wet assay less 1.5%:				
Up to 5%	Casting copper −6c	Casting copper −6c	Casting copper −6c	
5% to 10%	Casting copper −5c	Casting copper −5c		
10% or more	Casting copper −4c	Casting copper −4c		
Silica insoluble:

Treatment Charges	Gross Value	Charge	Gross Value	Charge		
	Up to $14	$5 00	Up to $35	$3 50	See Figure 3	Figure 3
	$14 to $20	6 00	$36 to $80	4 00		
	20 to 25	6 50	Over $80	4 50		
	25 to 30	7 00				
	30 to 35	7 50				
	35 to 40	8 00				
	40 to 45	8 50				
	45 to 50	9 00				
	Over $50	10				

The average lead content of the Colorado ores smelted from 1912 to 1916 was 6.76 per cent. Since this is below the requirements for economic lead smelting, the deficit therefore must be made up by the purchase of high-grade ore from outside the state.

General Remarks on Smelting

ZINC SMELTERS

The main requisites for a zinc smelter are cheap ore and cheap fuel. Where by-products are made, marketing facilities are also important. The Eastern zinc smelters are in the natural gas fields furnishing cheap fuel. The Missouri and Oklahoma ores are higher in grade and cheaper to produce than the Colorado ores and are more desirable for a zinc smelter. Owing to the increased cost of operation in Colorado, only crude ores of special composition are available, mainly impure complex zinc ores carrying gold and silver values.

The losses in zinc smelting are high and fuel consumption is heavy. The usual practice figures a loss of 8 units of metallic content and from 2½ to 3 tons of fuel per ton of ore smelted. Losses in percentage would vary from 12½ per cent on a 64 per cent zinc ore to 25 per cent on a 32 per cent ore. These losses are due to absorption by retorts (which is not recoverable), impurities, burning of zinc, and the formation of non-recoverable compounds. The deduction for freight would depend upon the location of the plant. Treatment charges will vary $16.00 to $22.00 per ton of ore.

LEAD SMELTERS

Low-grade ores are frequently produced in the prospecting for high-grade ores and also incidentally to the production of the latter. A sliding scale of treatment and purchase of these low-grade ores is justifiable in order to stimulate production. The loss to the smelter in smelting the low-grade ores must be borne by the high-grade ore in order to bring the average to a reasonably profitable basis. Should this not be done, the operations would be on a smaller scale, with proportionately increased costs for both.

In order to successfully operate a smelter the mixtures going to the furnaces cannot be varied from hour to hour. Therefore the smelters desire large and regular shipments. In consideration for a guaranteed supply of a definite tonnage at a fixed rate, concessions are made and these shipments are purchased under more favorable terms than the small irregular shipments. A small shipment requires as much work for the assaying and general charges as a large one, making the cost of handling proportionately higher.

A comparison of the open schedules with the average contract schedule, under which the bulk of the ore is purchased, would not be favorable to the shipper, because a contract for a guaranteed tonnage of ore of a desired content at a specified rate would be given advantages over the open schedule which represents small and intermittent shipments.

The essential requirement for a lead smelter is an ore mixture, to be so apportioned that a slag can be formed, from which the recovery of the metal values is made. The metallurgist may often have to sacrifice good practice to obtain the greatest profit. Barren fluxes not only cost money but also take up space and reduce the capacity. When fluxes contain metals of value they may be classed as a low-grade ore and treated accordingly. These low-grade ores may be purchased under special and variable rates according to the requirements of the plant. The slag formed from smelting an ore or a combination of ores will contain appreciable amounts of gold, silver, copper and lead, as well as the other constituents, no matter whether all the original ores contained these metals or not.

In smelting sulphide ores, roasting is necessary in preparation for the blast furnace, thus involving an

extra expense of operation and an increased metal loss due to volatilization.

The quantity of fuel required varies from 8 to 12 per cent, depending upon the amount of sulphur, the lead on the charge, and the temperature of the formation of an easy running slag.

The principal products from the blast furnace are slag, flue dust and fume, matte, speiss and bullion. All of these products contain metal values, and with the exception of the slag, must be retreated for their recovery.

When the ores contain small amounts of copper, as in the case of smelting lead-copper ores, retreatment is necessary to bring the copper into a marketable form for further concentration. Each stage of the retreatment involves the usual losses so that the ultimate recovery is relatively small.

The final recovery of lead from the ore in the average copper-lead furnace charge requires from one and one-quarter to two smeltings. For the recovery of the copper in the form of high-grade matte, two and one-half to three smeltings are required.

In cases where the amount of lead on the charge is small, in the first operation, the recovery in bullion will be about 65 per cent, in by-products to be retreated about 15 per cent, lost in the slag about 10 per cent, and 10 per cent will be volatilized. Part of the latter may be recovered in baghouses, according to the plant equipment. For the efficient collecting of values in a lead smelter, the percentage of lead on the charge should be around 10 per cent. In order to smelt locally to the best advantage the ores of the average lead content such as produced, it is necessary to obtain lead from another source to bring the charge to the economic requirement.

During the five years' operation from 1912 to 1916 the Colorado smelters produced approximately 441,000 tons of lead bullion, 50 per cent of which came from Colorado ores.

In copper-lead smelting, zinc in the ore is detrimental. It decreases the fluidity of the slag and lowers the specific gravity of the matte, thereby interfering with the settling. Losses are also increased and furnace operations are hampered. All of the zinc in the ore is a loss to the lead smelter and the slag from the Colorado smelter carries from 5 to 10 per cent zinc. Other substances, such as alumina, manganese, lime and magnesia, act differently in the blast furnace and are penalized or credited accordingly. Iron is a necessary flux and has only that value to the lead smelter. It goes into the slag and cannot be economically recovered.

The best slags will contain from 0.002 to 0.005 of an ounce of gold, from 0.50 to 1.00 oz. of silver per ton, from 0.20 per cent to 0.30 per cent of copper, and from 1.0 per cent to 1.50 per cent of lead.

In the usual blast furnace practice with an 8 to 10 per cent lead on the charge, the slag made represents from 60 per cent to 65 per cent of the charge, or 1 ton of slag for each ton of ore smelted. The matte fall is held at about 10 per cent. The matte will contain approximately: gold 0.05 oz. per ton, silver 40.0 oz. per ton, copper 10 per cent, lead 15 per cent, zinc 10 per cent, and iron 40 per cent, together with other ingredients, such as silica, alumina, etc. The second matte contains 40 per cent copper or better.

The baghouse product will contain something like 40 per cent lead, 10 per cent zinc, and such other volatile metals as arsenic, antimony, cadmium, etc.

LOSSES AND REFINING

The losses incident to smelting are slag, volatilization, and mechanical. The losses of gold are small and are due to slag and mechanical losses. Smelter operations often show a gain in gold due to the non-payment for gold when less than 0.02 to 0.05 of an ounce in the ore. The loss in silver is in the slag and possibly a small mechanical loss, and is provided for by paying for 95 per cent of the silver content. The copper loss is in the slag. The lead losses are in the slag and in the flue dust.

In the usual practice the following summary of losses will be representative:

Gold	0.005 oz. per ton of ore treated
Silver	1.0 oz. per ton of ore treated
Copper	6 lb. per ton of ore treated
Lead	30 lb. per ton of ore treated

In addition to the actual metallurgical losses in the smelting operations, it is necessary that the schedule provide for the refining and marketing of the metals recovered. The cost of refining and marketing of the gold and silver is small and charged to the lead bullion. A representative bullion refining charge is $25.00 per ton, which includes freight, etc., or one and one-quarter cents per pound (1¼ cents) of lead. A representative refining charge on 40 per cent copper matte is $40.00 per ton, including freight, etc., or five cents (5 cents) per pound of copper contained in the matte.

The refining and freight charges for the copper in lead ores are not to be compared with similar charges for the copper in an ore when sold to a copper smelter, as the latter ships a practically pure product, paying no freight on the impurities. A lead smelter ships 10 per cent copper matte and the freight for the same distance, other things being equal, would be two and one-half times as great.

CONCLUSION OF INVESTIGATING COMMITTEE

By reading the evidence in Mr. Caldwell's statement, it will be found that certain questions are asked by producers of ore. These questions embody completely the complaint against the smelters and ore buyers of the state.

The answers to three of these questions are found in Mr. Whitaker's report. In the matter of refining and marketing charges the committee has no power to investigate any corporation outside of the boundaries of the state and there are no refineries in Colorado. Hence we must submit only such facts as we have found. It costs 1¼ per cent per pound of lead to transport and refine bullion. It costs 5 cents per pound of copper to transport and refine copper matte.

In the matter of returns upon the investment the risk is taken upon the turnover and not upon the original investment. Hence fluctuation of the market in metal prices is the dangerous end of the smelting business. And as pointed out in the letter from the executive committee of the Colorado Metal Mining Association, the returns figured upon the investment of $2,700,000 is approximately 27 per cent while when figured upon the turnover is less than 4 per cent.

The smelters contend that the valuation is not high enough; that while the valuation placed by Mr. Whit-

aker on the plants does cover the actual physical value, much money is expended in building and operating many experimental processes. Many of these have to be abandoned, and represent a total loss to the smelting companies, and hence the claim that a higher valuation should be placed in order to cover the item of depreciation. While there is, doubtless, much truth in this contention, the fact remains that the figures used by Mr. Whitaker are in excess of the assessed valuation of the plants. While it is probable the plants could not be reproduced at these figures at present, they could be in normal times.

In the matter of zinc ores, it appears that zinc smelting in Colorado is really not an important factor in determining the price of ore. Out of 1,167,205 tons of zinc ore and concentrates produced in Colorado, there was treated in Colorado zinc smelters only 79,755 tons, or less than 7 per cent of the total. The schedules and prices of such ores are made and determined in the great zinc smelting centers in other states. The price in Colorado for such ore is absolutely made outside of the state.

In the matter of lead ore—and that is the most important phase of the committee's work, for it is between the producers of lead ores and the buyers that most of the complaints have arisen—much may be said.

New schedules have been voluntarily put into effect by the smelters and ore buyers during the year 1917. It is admitted by many producers, and is doubtless true, that these schedules eliminate much of the ground of complaint. Nevertheless the basic complaint is with the schedule itself. The committee believes that no schedule based upon the unit and quotation system will ever be satisfactory to the producer. It is hard for many producers of ore to understand, and unfortunately the smelters and ore buyers make no strenuous effort to explain it to those with whom they do business. Hence grew the belief that they were unjustly dealt with. And the committee believes that such an impression will prevail as long as such schedules remain. In the opinion of the committee the introduction of a new and easy understood schedule would go far toward eliminating the complaints in this matter.

Another matter which is subject of much unfavorable comment is the fixed minimum of 5 per cent on lead ores. Mr. Whitaker's report shows the average contents of Colorado produced lead ores was 6.76 per cent. When under 5 per cent the smelters and ore buyers do not pay for the lead contents, the reason assigned being that the cost of treatment would balance the value of the ore. Mr. Whitaker in his report finds that it is necessary to send low-grade lead ores twice through the furnace, in which case, of course, the saturation of the slag is sure to occur. This causes a loss of 30 lb. to the ton or 1.5 per cent. The two operations would therefore consume 3 per cent of the charge or 60 per cent of the lead contents of a 5 per cent ore. Now the cost of treatment is borne by all the metals in the charge and hence only a portion of it should be borne by the low-grade lead ore. Doubtless this is a source of profit to the smelters.

The committee believes that either the minimum should be reduced to 3 per cent on lead ore, or that the producer should be given the opportunity to have his ores smelted and by paying the charges therefore receive the bullion on 5 per cent and lower lead contents.

In the matter of copper in ores, Mr. Whitaker plainly points out that on account of the lack of copper in most Colorado ores the saturation of the slag which is 6 lb. to the ton, takes most of the copper contents. In a lead smelter ore with copper contents must be treated with ore that has no copper and requires several operations, each entailing a loss by saturation of slag. While the minimum of 1 per cent or 1½ per cent is an arbitrary one it is probably founded upon results of experience. With three or four operations each entailing a loss of 6 lb. copper it can be plainly seen that 1 per cent copper in the original ore would be lost.

The committee believes that some system of licensing umpires should be established. Some competent authority should be established which would issue licenses upon proper examination, and with power to revoke such in case of dishonesty or improper return or careless work.

The complaint about equipment seems to be well founded. The committee believes that sampling works should be inspected and required to maintain a certain standard of equipment. This duty could be properly assumed by the Commissioner of Mines' department.

Government Controls Acetone Supply.—All of the acetone produced in the United States has been commandeered by the Secretary of War for the six months ending June 30, 1918. Supplies of this material can only be secured now by means of a permit. This may be obtained through Mr. C. H. Conner, Council of National Defense Raw Materials Division, War Industries Board, Washington, D. C.

William Gibbs Gold Medal.—Dr. William M. Burton, vice-president of the Standard Oil Co. of Indiana, has been awarded the 1918 William Gibbs gold medal by the Chicago Section of the American Chemical Society. Dr. Burton entered the employ of the Standard Oil Co. soon after receiving his doctor's degree from Johns Hopkins in 1889. He is best known through the Burton process of oil refining, which he developed and which was brought to the attention of the public in 1913. The process has been a big factor in increasing our gasoline supply.

Russian Production of Rare Metals.—The Russian Bureau of Mining reports that no bismuth was produced in Russia during 1916 (Commerce Reports). Antimony was produced in such small quantities that no statistics have been gathered. Of molybdenum (MoS_2), only 150 poods (5417 lb.) were produced, all of which was used for domestic purposes. The value cannot be ascertained. About 2000 poods (72,220 lb.) of tungsten, concentrated (60-65 per cent WO_3), was produced, the value of which is not given. The total amount was used in Russia. Since 1914 all bismuth, molybdenum and tungsten have been used for war purposes. In 1917 it is estimated that 6000 poods (216,680 lb.) of tungsten ore (65 per cent WO^3), 50 poods (1806 lb.) of bismuth ore (60 per cent Bi), and 200 poods (7220 lb.) of molybdenum (45 per cent Mo) were produced.

Saving in Transportation.—A considerable saving in transportation has been effected by fertilizer manufacturers by loading railway cars up to capacity, and then a little more. A freight car is not like a truck for heavy material to be pulled by a team of horses. The engine can pull it. And every car counts.

Synopsis of Recent Metallurgical and Chemical Literature

Log of An Electric Furnace.—E. A. SUVERKROP presents a description of the manufacture of electric-furnace tool steel as practised at the Watervliet works of the Ludlum Steel Company in the American Machinist of Feb. 28, 1918. Of considerable metallurgical interest is the following log covering one heat of an arc-furnace (style and capacity not given, but possibly making about seven tons per heat):

4:55—Charge started with furnace full of cold metal. Lime and mill scale added at start for dephosphorizing slag. Balance of charge added when the melting of the scrap provided sufficient room. The temperature of the melting stage is kept as low as possible to effectively remove the phosphorus.

9.16—Metal boiling; slag thinned by two shovels of silica. Slag rabbled.

9.24—Metal quiet and sampled for analysis. Slag black.

9:30—Lime added to slag to thicken, preparatory to removal.

9:35—Current off; black dephosphorizing slag raked off.

	Analysis of Melt	Analysis Desired
Carbon	0.59	0.95
Silicon		0.15
Manganese		0.20
Chromium	0.37	0.45
Phosphorus	0.018	0.015
Sulphur	0.025	0.012

9:39—Ten shovels of a mixture of lime, fluorspar and sand added to make second slag.

9:45—Slag sampled—was thin, showing some unfused lime.

9:53—Slag sampled—smooth and thin, color gray, condition reducing.

9:54—Metal sampled for analysis. Current off.

10:00—Slag temperature, 2573 deg. F.

10:02—Current on.

10:03—Five shovels of dope added to reinforce desulphurizing action of slag.

10:08—Slag sampled, condition good, as noted at 9:53.

10:10—Lime added to thicken slag preparatory to removal.

10:12—Current off.

10:14—Slag very thick and easily raked off. Metal 2570 deg. F.

10:20—Weighed amount of carbon added to metal.

10:22—Furnace doors luted to exclude air.

10:40—Furnace unsealed. Metal 2596 deg. F. Third slag made of seven shovels of mixture of lime, fluospar and sand.

10:52—Slag sampled, color gray and in excellent condition. Alloy added to bath.

10:59—Slag shows slight greenish tint, due to chromium.

11:02—Sample of slag and metal sent to laboratory for analysis. Slag temperature 2662 deg. F.

11:05—Current off. Green color in slag fading.

11:08—Slag 2652 deg. F. Current off waiting analysis. Ladles being preheated.

11:32—Slag too thin, four shovels lime added.

11:35—Slag in excellent condition, brownish gray color.

11:42—Additions of alloys to correct analysis made.

11:52—Test bar of metal forged to determine mechanical condition.

11:53—Metal agitated to perfect mixture.

11:55—Slag sampled, small quantity of lime added to bring it to exactly neutral condition. Temperature 2650 deg. F.

11:58—Small amount of ferro-silicon added to melt. Surface of melt quiet.

12:06—Additions of fluospar and silica to slag. Temperature 2690 deg. F. Current off.

As the metal was poured into the ladle, the temperature was taken as 2641 deg. F. and had dropped to 2640 when the first ingot was poured. Seventeen ingots were poured, each taking about 35 seconds. Temperature of the last ingot 2550 deg. F. The second ladle of metal came from the furnace at 2618 deg. F., the first ingot was poured at 2600, and, after thirty-five smaller ingots, the last was poured at 2575 deg. F.

Developments in By-Product Coking.—A paper on this subject was read before the December meeting of the Institution of Civil Engineers (British) by GEORGE B. WALKER. The author stated that the aim in recent designs was to secure better equalization of heat in all parts of the oven walls, to equalize the pressure between retort and heating flues, to reduce the time of coking, to facilitate inspection and regulation of all parts of the oven, to increase the yield of ammonia and benzol, and to economize in the use of gas for heating the ovens. The so-called "direct" process for the recovery of ammonium sulphate was shown to be more advantageous than the older practices, since the recovery of the nitrogen is performed without the use of condensers, coolers or scrubbers, consequently eliminating the need of a large quantity of cooling water with the attendant loss of heat, and being therefore independent of the temperature or the season. The plant is said to be no more expensive to construct or maintain than that for the scrubber process, and no noxious effluent is produced whether or not benzol is recovered.

The advantage of regenerative working is clearly brought out by the following generalizations: Assuming a battery of 50 modern by-product ovens, each having a capacity of 10 tons damp coal and carbonizing five charges per week, 2750 tons of coal (containing 30 per cent volatile and yielding at least 10,000 cu. ft. gas per tons) would be coked in that time. Running with waste heat boilers and no regenerators the exit gases at about 800 deg. C. should evaporate 500 gallons of water per hour, which would produce steam for non-condensing engines producing approximately 1200 hp. In addition there would be a small amount of surplus gas available. If, however, the ovens were equipped with regenerative checkerwork, the consequent use of highly heated air for combustion in the oven-flues reduces the consumption of scrubbed gas at this point sometimes to a figure as low as 40 per cent of that evolved. Supposing, however, that only 40 per cent of the gas was available for use in internal combustion engines, 2180 hp. could be produced therefrom, reckoning 30 feet of gas per horse-power-hour.

Steel Turnings and the Electric Furnace.—A note on this subject is given in the *Iron and Coal Trade Review* (London) for Dec. 21. 1917, by JOHN A. HOLDEN. He says that a few years ago steel turnings were not in very much demand, and good, clean turnings could be bought for 30s. per ton. The price to-day for the same metal is about £4 per ton, a figure which would, no doubt, have been exceeded but for the intervention of the Ministry of Munitions. He says the reason for this appreciation is not difficult to seek. The raw material for the manufacture of electric steel in the arc type of furnace consists almost entirely of turnings. The writer refers to those furnaces which are worked with cold stock. Incidentally, it may be added, in England very few furnaces are worked with liquid charges.

Fifty 3-ton electric furnaces would consume annually 150,000 tons of steel turnings. In addition, turnings often form a portion of a Siemens charge, and sometimes they are used in blast-furnace charges. For producing electric carbon tool steel mild-steel turnings from shells are in much demand. Nickel-steel turnings are used for the manufacture of nickel-steel ingots. With a suitable grade of scrap no addition of nickel may be required, because in any type of electric furnace there is no oxidation of nickel.

Similarly, nickel-chrome-steel turnings may be profitably converted into nickel-chrome-steel ingots. In acid-lined furnaces there is little or no loss of chromium; in fact, the reactions in this furnace are comparable to those of the crucible process. In basic-lined furnaces chromium may be retained or eliminated. In the former case the phosphorus would not be so completely oxidized, but nevertheless it would be confined to safe limits. It follows that for the cheap production of alloy steels, such as nickel and nickel-chromium, scrap turnings containing the necessary elements should always be used.

From an economic point of view, it is undesirable that alloy-steel turnings should be used in charges where the alloying elements are not necessary or desirable. Many engineering establishments do not keep all these varieties of scrap separate. They may religiously look after high-speed steel, but other alloy steels are mixed with plain carbon-steel turnings. In addition, the heaps of turnings sometimes become a dump for waste paper, or even worse refuse, etc. In those shops where the amount of scrap produced is very small, it may not be economically possible to separate the different varieties. Unfortunately, there are works producing weekly as much as 100 tons of turnings consisting of only two varieties, yet they do not trouble to keep them separate.

One example will suffice to illustrate the loss when nickel steel is used in charges where nickel is not necessary. Fifty tons of 3 per cent nickel steel scrap contain £300 worth of nickel. Taking 50 tons as a weekly average, it represents potentially £15,000 per annum. Whilst every electric steel smelter desires short heavy turnings, it has been found practicable to crush the lighter turnings and obtain results equal to those obtained by the use of the more expensive and weighty turnings.

Action of Caustic Liquors on Steel Plates.—Two interesting articles have recently appeared in the *Chemical Trade Journal and Chemical Engineer* (London) on the action of caustic liquors on steel plates. The subject is a very important one. In the first article (Dec. 22, 1917), C. E. STROMEYER discusses tests which he made with the idea of determining the effect of stresses and whether they were the cause of cracks. He experienced great difficulty in maintaining the test pieces in a strained condition. Pieces strained before being acted on by caustic would have no stress afterward. He states that this experience was very disconcerting, and may account for the results obtained by Professors Heyn of England and Parr of the United States who could detect no effect due to straining. The experience is, however, not without practical interest, as it points to a possibility that caustic liquor may cause a slacking back of rivets and caulked edges and lead to leakages. He thinks it will be no easy matter to devise tests which will maintain the samples in a strained condition, for in his experiments the stress had to be produced by the elasticity of the material, and if that fails the stress disappears. The case is different in a boiler, for there the stress is due to the boiler pressure, and though the caustic may relieve some stresses, as is shown by the flying off of rivet heads, the average stresses will be maintained, and some local stresses may even be increased.

Professor Heyn has published nothing on this subject, but wrote that he could not confirm the writer's results. Professor Parr, in the 94th Bulletin of the Illinois University, deals with the following points. He notes a change of electric potential if steel is immersed in caustic. The tensile tests showed a reduction of tenacity of about 30 per cent after treatment, but this reduction was not influenced by change of density of the liquor. The elongation improved about 10 per cent. The samples which were stressed during exposure behaved in the same way. Judging by his experiments and the description of Professor Parr's, the author thinks it doubtful whether his samples were really stressed while exposed. He also submitted some of his exposed samples to alternate (fatigue) stresses, and found about 20 per cent reduction in the number of reversals of stress before fracture occurred. The impact test results were about 10 per cent lower for the treated than for the untreated specimens. Professor Parr's most important results are his determination of the hydrogen which is absorbed by steel and iron when immersed in caustic soda, and, as it is well known that hydrogen makes certain steels very brittle, these determinations should explain the brittleness. However, as already stated, this brittleness seems to be produced only if the steel is stressed during exposure, but details of the conditions have not yet been determined. In the writer's experiments a change of density could not be detected.

The second article by ERNEST WORSLEY (Jan. 26, 1918) deals especially with vacuum evaporators. The author does not believe that the action of the caustic on the metal during tension is the sole cause of breakage, and cites numerous examples to prove this. He says the breakage occurs with other liquors, such as glue, and that the only sure way of preventing the breakage altogether is to use Mannesmann tubes. These tubes will not, however, resist corrosion and there appears to be some relation between the breaking of tubes and the internal wear, as tubes which break do not wear and vice versa. Another curious feature about the breaking of the tube is that the fracture always occurs at the

ends—never in the middle portion. The author concludes from the examples which he cites from plants in actual operation—that the breakage of tubes in vacuum evaporators is not due to caustic liquor any more than to any other liquid and can be prevented only by the proper selection of tubes, *i.e.*, tubes made of steel, which can be annealed without any sign of "shortness."

The Groch Flotation Machine.—A new flotation machine is described in the Canadian Mining Institute Bulletin, March, 1918, by F. O. GROCH and W. E. SIMPSON. As is seen by the sketch, the chief distinctive feature is a centrifugal impeller which has hollow hubs and is subdivided horizontally by a metal disc so as to

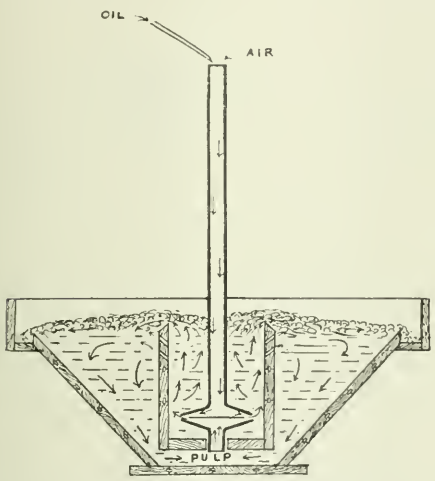

DIAGRAM ILLUSTRATING ACTION OF THE GROCH FLOTATION MACHINE

operate after the manner of a pair of centrifugal pumps. The pulp enters the treatment zone by being sucked up into the lower "runner" and ejected centrifugally at the periphery in a horizontal plane, where it must rise through a similar sheet of air and atomized oil (The system therefore gives most intimate contact between the ore particles and the finely divided air and oil.) The vacuum created at the discharge amounts to 2.75 inches of mercury at 450 r.p.m. and 6 inches at 750 r.p.m.

This machine eliminates the disadvantage associated with machines using the blade type of impeller of having to beat the air into the pulp by the creation of a deep vortex. Consequently the power consumption is quite low, a standard machine of six impellers with a capacity of about 55 tons of ore per day consumes 7.5 hp. The machine has been used on silver and molybdenite ores in the Cobalt region with marked success.

Basalt Lava for Filtration Purposes.—An article in Schweizerische Bauzeitung, Jan. 5, 1918, abstracted from Zeit. der Verein Deutscher Ingeniaur, states that experiments with finely crushed lava from extinct volcanoes in Central Germany have shown that this material is an excellent substitute for kieselguhr in the filtration of drinking water. Drs. Hambloch and Morziol take the lava deposits, grind them to a finely granulated condition, and wash them in a solution of sodium carbonate or in diluted hydrochloric acid. Roasting the granulated product preparatory to washing increases its cleansing qualities as well as its plasticity.

Recovery of Ammonia from Gas.—In the *Gas Record* for Feb. 27, 1918, Dr. JOHN S. UNGER, in an article on this subject, states that there are many good-sized coal-gas works in the country in which no income is derived from ammonia recovery. He says it should be the ambition of every manager of a coal-gas works, carbonizing 3000 tons of coal per year and over, to obtain an ammonia still and make concentrated gas liquor in small works, sulphate and aqua ammonia in larger works. He emphasizes particularly the advisability of using a modern high-grade still with adequate controlling devices. He describes a plant in Illinois which produced 36,511 lb. of concentrated ammonia in 1917 from 8166 tons of coal, or a yield of 4.5 lb. per ton. One year's operation paid for the cost of installation. When using two-thirds Kentucky and one-third Illinois coal the recovery is 5.25 lb. ammonia per ton of coal. It is estimated that we will need 150,000,000 lb. of ammonia this year for munitions and 40,000,000 for cold storage. Our production last year was 130,000,000 and we will have a severe shortage unless all sources are producing.

Recent Metallurgical and Chemical Patents

Dyes and Intermediates

Production of Beta-Naphthol Benzoate.—GUSTAV BLIEBERGER of New York patents a process which he assigns to the Anthony-Hammond Chemical Works of New York. He produces benzoyl chloride by heating together benzoic acid and phosphorus trichloride or penta chloride. The benzoyl chloride is then dropped on molten beta naphthol and any benzoyl chloride evaporated is caught in a reflex condenser. The beta naphthol benzoate thus formed is dissolved in alcohol and recrystallized. (1,254,970, Jan. 29, 1918.)

Vegetable Dye.—ISIDOR KITSEE of Philadelphia, Pa., patents a fast dye made by adding two metallic compounds to logwood. Chloride of zinc, copper ammonium chloride, chloride of tin, hydrochloric acid, and other compounds are added according to the color desired. (1,254,914, Jan. 29, 1918.)

Benzene-Naphthalene Dyes.—A patent issued to HEINRICH GRÜNHAGEN of Germany refers to the manufacture of dyes of the benzene-naphthalene acridin series. The dyes are made by heating a formyl derivative of a beta naphthylamine such as formyl-2-naphthylamine and a salt of a meta-diamine of the benzene series such as amino-dimethylaniline hydrochloride. The melt is dissolved in water and the dye precipitated with salt and zinc chloride. (1,255,740, Feb. 5, 1918.) Another patent issued to the above refers to halogenated dyes of the acridine series obtained by heating a halogen derivative of a formyl-meta-diamine of the benzene series with a salt of an aromatic meta-diamine. (1,255,739, Feb. 5, 1918.)

Apparatus

Evaporation Apparatus. — Dr. EDWARD HART of Easton, Pa., patents an evaporating apparatus particularly applicable to acids. A series of horizontal cylindrical tubes are placed in cascade as shown in Fig. 1.

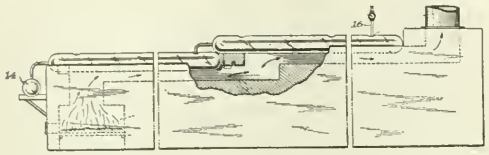

FIG. 1. SIDE VIEW OF HART EVAPORATOR

The tubes are either made of or lined with glass. The more or less dilute liquid enters the uppermost evaporators at a rate somewhat faster than it can be evaporated. The excess escapes into the next lower evaporators of the cascade and is finally delivered to the manifold 14, whence it is discharged by a pipe from 14 into any suitable receptacle, not shown. The evaporators being elongated, the liquid entering at one end of an evaporator has ample opportunity to mix thoroughly with the liquid (more or less concentrated) in the evaporator, before the overflow pipe at the opposite end is reached. The thorough mixing is important, and is due to several factors. First, the liquid entering any given evaporator is somewhat cooler than the liquid therein, thus causing a tendency of the incoming liquid to sink. Second, the convection currents are active and rapid because of the heating of the bottoms and the cooling effect of evaporation at the surface. Third, when boiling is permitted the ebullition agitates the liquid more or less strongly. The result is that if the supply by way of the pipes 16 is properly regulated the liquid in each evaporator is thoroughly homogeneous by the time it reaches the outlet pipe, so that the liquid escaping is no more and no less concentrated than the liquid remaining.

The evaporators and the receiving manifold at the end are simply laid on their supports and the discharge orifices of the supply and outlet pipes are free, so that any of the several vessels can be easily removed and replaced. While the total quantity of liquid in the system may be quite large, the quantity in any particular vessel may be relatively small. Breakage of a vessel is thus not the serious matter that it is in the case of a large receptacle, and replacement of a broken part is correspondingly cheaper and easier. If desired a dome may be arranged over the apparatus to collect the escaping vapors. (1,254,689, Jan. 29, 1918.)

Miscellaneous Processes and Products

Chlorine and Sodium Sulphate.—HERMAN B. KIPPER of New York City patents a catalytic process of producing chlorine and sodium sulphate. It is claimed that this process is much cheaper than the electrolytic or manganese chloride process. The process is based on the action of sulphur dioxide, water and oxygen, on sodium chloride. A catalyst such as ferric oxide is used in order to prevent the formation of hydrochloric acid. The temperature used is 400 to 600 deg. C. The process is carried out in a closed horizontal revolving iron cylinder similar to a roasting cylinder. There is an inlet tube at one end and an outlet at the other. Powdered sodium chloride is introduced through a hopper at the inlet and the catalyst is made up in the form of large balls so that they travel through the cylinder and are easily separated from the sodium sulphate formed. These balls are made from ground ferric oxide and sodium sulphate. The sulphur dioxide is introduced through the same tube as the salt. A flange on the inside of the drum raises the sodium sulphate formed and discharges it at the discharge end. The drum is continuously rotated. (1,255,020, Jan. 29, 1918.)

Drying Oils.—FELIX C. THIELE of Coffeyville, Kan., assigns a patent on drying oil manufacture to The Cudahy Refining Company of Coffeyville, Kan. Kerosene is treated with a halogen such as chlorine, then acidulated with acetic acid and treated with a metal such as zinc. (1,254,866, Jan. 29, 1918.)

Distillation of Coal.—CHARLES FOXWELL of Baltimore proposes to add to coal before distillation a substance which will not give up its entire water until a temperature has been reached at which all the desired products are given off. This is preferably accomplished by treating the combustible materials before they are distilled, with a water solution of calcium chloride and an oxygen-bearing compound of boron. This will retard combustion owing to the water being slowly expelled from the added solution, some of the water being retained even until after attainment of a temperature sufficient to volatilize all of the distillate sought after. In other words, by the time all the water has been expelled from the chemical compound the by-products will have been distilled over, and the fire may thereafter be regulated with respect to the product, for example coke, to be obtained from the base of the combustible material. Commercial borax ($Na_2B_4O_7$) serves well for the boron compound, and this being dissolved in water, together with calcium chloride, in the proportions of, say, 382 lb. of commercial borax to 918 lb. of calcium chloride of 72 per cent purity, will make the chlorine and boron molecularly equivalent. In practice, the material is springled with the solution in sufficient quantity, the material being thoroughly mixed or turned over during the treatment. When so treated, the material is ready to be distilled. (1,255,593, Feb. 5, 1918.)

Electric Furnaces

Induction Furnaces.—J. R. WYATT of Philadelphia, Pa., patents a variety of forms of induction furnaces (assigned to Ajax Metal Company) consisting of a large pool of molten metal heated by the circulation of hot metal driven through attached channels. These channels form the secondary circuits of enclosing transformers, and may be placed at various angles and in various combinations to the sides of the main pool or below it, and as many in number as required by the construction or by the number of phases of current used. As is shown in Figs. 2 and 3, which illustrate the simplest design, the secondary channels (36 and 37) are straight and intersect at the outer end in an acute angle (35). The length, width and height of the channel will be dictated by the total resistance desired in the secondary—using a given melt—the dimensions of the pool, and the location of the channels. The induced current in opposite directions in adjacent channels containing a molten conductor results in a motor

effect tending to separate the conductor, which face varies as the product of the currents in the two conductors and inversely as the distance between the parts of the molten metal affected. Consequently the motor effect is intensified at any angle in the conductor, increasing with the sharpness of the angle until counterbalanced by increase in friction at such a point. Joule effect is not very effective in comparison. A narrow channel intensifies the

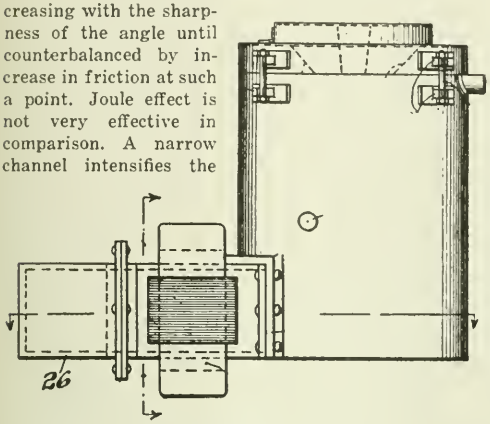

FIG. 2. SIDE ELEVATION

effect at the corner, but increases fluid friction, while a high channel receives a large transformer flux. In a brass furnace having a channel beneath the pool, a pouring heat of over 200 pounds, and a secondary current of 7000 or 8000 amperes, excellent results were had with a channel 18 inches long by 3 inches high by ⅝ inch wide.

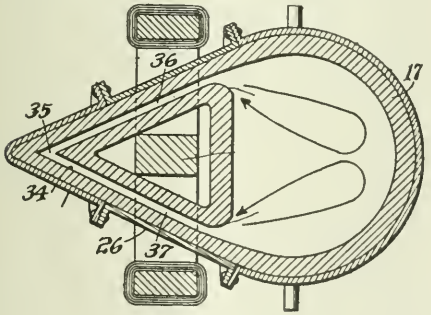

FIG. 3. SECTIONAL PLAN 2-2

In operation it is quite desirable to pour the initial charge from another furnace. The current is then turned on and heating of that charge and material added from time to time is effected by the secondary current. The hotter metal is driven out along the outer sides of channels 36 and 37, and is replaced by a flow of cooler metal from the pool passing along the inner sides of the same channel sections, heating the pool by the additional heat of the hotter metal withdrawn and stirring the pool by the flow, with a resultant intermingling of the hotter metal with that of the pool and gradual and nearly uniform increase of temperature throughout the pool. A narrow stream of hot metal ejected at considerable speed is much more effective than the same quantity delivered in a larger stream at a lower rate, since the stirring effect and immediate distribution obtained by the higher speed reduces the amount of mixing which must be accomplished by the slower Joule effect.

The casing 26 may be jointed at several points and separated by asbestos insulation to reduce the secondary current in the casing; or the furnace lining 17 and 34 may be itself a conductor of the first class in case a low-melting alloy of high resistivity is to be melted. In the latter case the furnace can be entirely drained at each cast; in the former, it must not be tilted to such a high angle as to break the molten secondary. The rounding of the junction (42) between channel and pool is necessary to reduce motor effect at these points. The furnace is particularly adapted for remelting chips or turnings of brass and other alloys. It is necessary to superheat these melts several hundred degrees above their melting points in order to pour good castings, in which case the vaporization of one or more components of the charge is usually quite serious. In this furnace any metal vaporized in the secondary channels is condensed before reaching the surface of the pool. (1,235,628, 1,235,629 and 1,235,630; Aug. 7, 1917).

Electrolytic Processes

Anode Suspension.—F. L. ANTISELL of Perth Amboy, N. J., points out the following difficulties in the manufacture and use of anodes with cast lugs: Thin lugs and anodes are hard to cast owing to chilling of the metal in the mold, even though it is desirable to pack as many into one tank as possible. Cast lugs are often warped, causing anodes to hang out of plumb and rough, causing poor electrical contact where they rest on the sides of the tank. Lugs are liable to damage in shipping, and cause a large amount of unelectrolysed scrap. They cannot be passed through rolls to smooth out irregularities. These objections hold in general anodes hung from hooks or links from rods, with the additional objection that one or two additional contacts are introduced, each consuming about 10 per cent of the total power used in refining.

His improved suspension is illustrated in Fig. 4,

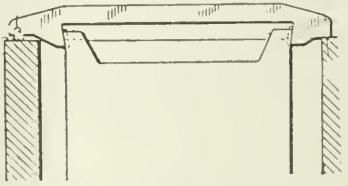

FIG. 4. METHOD OF ANODE SUSPENSION

where the suspension bar has V-shaped knife edges engaging in inclined slots in the edge of the anode. Good electrical contact at this point is insured by wedge action, giving up to four times the pressure of the weight of the anode, noting that by actual experience it has been found that within the range of current densities and voltages prevalent in copper refineries the reduction in resistance of the contact is about proportional to the pressure of contact. Using a suspension bar of refined copper has additional effect in reducing the resistance of the combination, which is claimed to reduce the contact loss from 10 per cent to 2½ per cent or less. (1,250,757, Dec. 18, 1917.)

Continuous Process of Causticizing Soda-Ash with Lime

IN VIEW of the fact that a majority of the paper mills in this country make their caustic liquors by an intermittent process of agitation and decantation, considerable interest attaches to a continuous process of causticizing soda-ash with lime, which has now been in operation for ten months at the mill of the Kingsport Pulp Corporation, Kingsport, Tenn.

The system employed in this mill is an adaptation of the well known metallurgical methods of continuous agitation and continuous counter-current decantation. The cyanide process of treating ores is analogous in many ways to the manufacture of caustic soda liquors, as there is, first, a chemical reaction to be carried on requiring agitation of the solids and liquor for a given time, resulting in a valuable liquor, and second, a valueless product from which the liquor must be recovered. From this

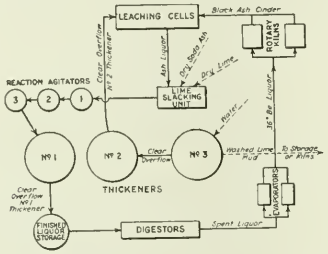

FIG. 1. FLOW OF SPENT LIQUOR

it will be noted that standard cyanide practice has been adopted, for in the Dorr continuous causticizing system continuous agitation is employed and the lime mud formed in the reaction agitators is continuously collected and washed in Dorr thickeners arranged to operate in a continuous and counter-current series. The agitating tanks are designed to give a retention period which will allow the reaction between the soda-ash and lime to come to equilibrium.

The feasibility of adapting this process to the manufacture of caustic soda liquors was demonstrated early in 1916 in a small-scale commercial plant capable of producing about 2½ tons of caustic soda per day. This was the largest plant of its kind that had been built at the time the Kingsport Pulp Corporation decided to adopt the system.

The Kingsport caustic plant was designed to produce 50 tons of 100 per cent NaOH per 24 hours in either a 10 deg. Be. or a 14 deg. Be. liquor. It has operated continuously for the last ten months and the ease of control, safety in handling and flexibility of the plant eliminate any fair comparison between the old and the new methods. Further, the absolute uniformity in strength of liquor produced permits the digester schedule to be maintained at maximum capacity.

Fig. 1 shows diagrammatically the flow of spent liquor from the digesters through the evaporators and recovery apparatus, and finally through the causticizing equipment. In plants as now designed the lime-slacking unit comprises a standard tube-mill and a Dorr classifier working in closed circuit, *i.e.*, the discharge of the tube-mill flows to the classifier and the coarse, unfinished product separated from the milk of lime is returned to the tube-mill, joining original feed. The finished product overflows the classifier. Soda-ash liquor, dry soda-ash and dry lime are introduced in this unit.

A mechanical feeder, adjustable to close control, delivers crushed lime from a bin to the tube-mill. By the operation of this continuous system of making milk of lime, all handwork is eliminated, the waste of lime and the labor required for cleaning out sand from slaking tanks is obviated, and absolute uniformity of the milk of lime is assured. Any unburned lime rock or silica is taken care of, as it is ground to such a fineness before leaving this system that it passes through the reaction agitators and thickeners mixed with the lime mud and causes no trouble. By the use of a classifier working in closed circuit with a tube-mill, the grinding efficiency is raised to a maximum, and small mills which require little power can be used so that continuous lime slaking by this method means a saving of power over slaking in tanks with paddle agitators.

The reaction between the soda-ash or soda-ash liquor and lime takes place in the three Dorr agitators. These machines are similar to those used in ore treatment, except that the whole mechanism can be raised so that the arms cannot get stuck in case of a shut-down. The agitators are equipped with covers and steam coils and operate at a temperature of 95 deg. C.

The mixture flows from the agitators to the series of Dorr thickeners where the continuous separation of caustic liquor is made. The thickened lime mud is transferred from the bottom of one thickener to the top of another by means of diaphragm pumps. The Dorrco diaphragm pump has an adjustable eccentric so that the length of stroke can be set from 0 to 3 in. The density of the thickener underflow is controlled by the number of strokes per minute, the length of the strokes, and by allowing air to enter the bowl compartment of the pump. These pumps have been used in caustic work for about two years, handling the thick, hot mud, and practice has shown that there is no upkeep cost except for an occasional change of diaphragm. The rubber diaphragms are readily replaceable without dismantling the pump, the average life being about two months.

All of the water entering the system is introduced at No. 3 thickener where the pump discharges its mud drawn from No. 2 thickener to the mixing launder. This launder is a steel trough with baffles laid in the bottom so that the lime mud and water are thoroughly mixed to form a uniform feed for the thickener. The clear liquor overflowing No. 3 thickener joins the lime mud from No. 1 thickener and is mixed with it in like manner to form a homogeneous feed for No. 2 thickener. The clear liquor overflowing No. 2 goes to the black-ash leaching cells and the effluent from these, after being built up with dry soda-ash, is used partly in the closed-circuit lime-slacking system, the balance going direct to the reaction agitators.

The percentage recovery of caustic soda by the washing process will depend upon the number of thickeners used and the amount of wash water that may be added, the latter being governed by the density of finished liquor that is required. When producing a 15 deg. Be. liquor and using three thickeners, a 99.7 per cent recovery of caustic soda is assured.

An interesting feature in connection with this process is the mathematical nicety with which it is possible to

calculate the percentage of the total caustic that will be recovered by a given number of thickeners.

Fig. 2 shows a conventional flow-sheet of a continuous causticizing plant based on the assumptions made

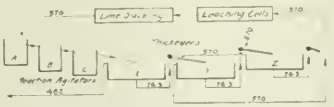

FIG. 2. CONTINUOUS COUNTER-CURRENT CAUSTISIZING PLANT

below. The figures given on the flow-sheet represent the tons of water flowing into and out of each unit.

Assumptions

Plant to produce 50 tons NaOH per 24 hours
Solution to be approximately 9.4 per cent NaOH (14 deg. Be.)
Black-ash leach-liquor to be recausticized
Agitation period 2 hours
50 per cent H_2O in thickener underflows
Yield to be 93 per cent
Na_2CO_3 ratio to be 10:6

Calculations

$$\underset{106}{Na_2CO} + \underset{56}{CaO} = \underset{62}{Na_2O} + \underset{100}{CaCO}$$

$$\underset{62}{C} \quad \underset{18}{E} \quad 50 \text{ tons}$$
$$Na_2O + H_2O = 2NaOH$$
$$\underset{80}{}$$

C : 62 = 50 : 80
C = 38.75 tons theoretical Na_2O = 93 per cent
F = 41.65 tons required Na_2O = 100 per cent

A : 106 = 41.65 : 62
A = 71.25 tons Na_2CO required

71.25 : B = 10 : 6
B = 42.75 tons CaO required

D : 100 = 42.75 : 56
D = 76.3 tons lime mud produced

E : 18 = 50 : 80
Water : solid = 1 : 1
E = 11.7 tons water required for reaction.
76.3 tons water lost with lime mud.

50 tons = 9.4%
532 tons = 100%
532 — 50 = 482.0 tons water with finished caustic liquor.
570.0 tons total water required.

Let X, Y and Z equal the value of the caustic liquor in each thickener in lb. of NaOH per ton of water.

By equating the expression for the amount of NaOH entering and leaving each thickener, the following simultaneous equations are obtained:

(1) 582X + 76.3X = 570Y + 100,000 lb. NaOH
(2) 570Y + 76.3Y = 76.3X + 570Z
(3) 570Z + 76.3Z = 76.3Y

Or

(1) 558.3X = 570Y − 100,000
(2) 646.3Y = 76.3X + 570Z
(3) 646.3Z = 76.3Y

Solving

(3)
646.3Z = 76.3Y
Z = .118Y

Substituting value of Z in terms of Y in (2)
646.3Y = 76.3X + 570 (.118Y)
579 Y = 76.3X
Y = .1317X

Substituting value of Y in tons of X in (1)
558.3X = 570 (.1317X) + 100,000
483.2X = 100,000
X = 207 lb.
Y = 27.5 lb.
Z = 3.28 lb.

The 482 tons of water going to storage with the finished liquor will carry 207 lb. NaOH per ton, or	99,751 lb.
The 76.3 tons of water going to waste with the lime mud will carry 3.28 lb. NaOH per ton, or	250 lb.
Total	100,001 lb.
Error due to neglect of decimals	1 lb.

Washing efficiency or recovery, 99.75 per cent.

Derivation of Above Equation

The total amount of NaOH leaving each thickener per 24 hours must equal the total amount entering it. Reference to the flow-sheet shows that 482 tons of water carrying X lb. of NaOH per ton leave thickener X and go to storage; 76.3 tons of water carrying X lb. NaOH per ton leave with the lime mud and enter thickener Y. Entering thickener X we have 570 tons of water carrying Y lb. NaOH per ton plus 50 tons of NaOH produced in the agitators. Entering thickener Y we have 76.3 tons of water with the lime mud from thickener X carrying X lb. NaOH per ton and 570 tons of water in the overflow from thickener Z carrying Z lb. NaOH per ton. Leaving thickener Y we have 570 tons of water carrying Y lb. NaOH per ton in the overflow, 76.3 tons af water carrying Y lb. NaOH per ton in the underflow. Entering thickener Z we have 76.3 tons of water in the underflow from thickener Y, carrying Y lb. NaOH per ton. The water entering thickener Z carries no value in NaOH, and hence 76.3Y is the only NaOH entering thickener Z. Leaving thickener Z we have 570 tons in the overflow carrying Z lb. per ton, and 76.3 tons in the underflow carrying Z lb. per ton.

Recent estimates made by the Dorr Company based on producing about 40 tons per day of caustic soda show that the total production cost exclusive of the cost of raw materials, is approximately 47 cents per ton of 100 per cent NaOH, with labor at 30 cents per hour and power at 2 cents per kw.-hr. This system of causticizing has been adopted by the Du Pont Engineering Company for a plant to produce 39 tons of caustic soda per day, which is to be built in connection with a plant now under construction for the United States government, and also by the Air Nitrates Corporation in connection with the plant they are building for the government at Muscle Shoals, Ala.

U. S. Trade with New Zealand.—The imports from American sources to New Zealand in 1915 were valued at $12,500,000, in 1916 at $19,000,000 and in the first six months of 1917 were $9,000,000. Paints and varnishes form an important part of the imports, while microscopes have also been sold in increased numbers. Petroleum products have also increased.

Personal

MR. EARL ADAMS, lately sales manager, powdered coal department, Bonnot Company, Canton, Ohio, and for some years in charge of gas producer work for The Power & Mining Machinery Co., has accepted a position as sales engineer for the Smith Gas Engineering Company and will shortly be located at Dayton, Ohio, where the new plant of the Smith Gas Engineering Company is nearing completion. A. B. MORRISON, JR., has also recently accepted a position with the company as sales engineer. Mr. Morrison was formerly with the Fort Wayne Electric Works and the Rathbun-Jones Engineering Company, and more recently with the John H. McGowan Company as Philadelphia representative.

MR. WILMER C. DUTTON of the Tolhurst Machine Works, Troy, N. Y., has been elected vice-president of the company and will be located at the New York office, at 111 Broadway.

DR. F. A. FAHRENWALD, consulting mining engineer and metallurgist, of Cleveland, will be in the West on professional business from about March 25 to May 10: the first two weeks in New Mexico and Arizona; the next two weeks in California and Nevada, and the remainder of the period in the Northwest.

MR. WILLIAM J. GROSS, formerly with the Sherwin-Williams Co., at Chicago, is now chief chemist of the Nordyke & Marmon Co., Inc., of Indianapolis, large manufacturers of automobiles and machinery. The Nordyke & Marmon Co. is doing extensive war work for the government.

Mr. ROBERT M. KEENEY, manager of the Ferro Alloy Company, Denver, Col., is acting as consulting engineer to the Anaconda Copper Mining Company on the manufacture of ferromanganese which the company is planning to start. He is in charge of construction and operation, but retains his connection with the Ferro Alloy Co., spending ten days per month in Great Falls.

DR. F. G. KEYES, formerly chief engineer of the Cooper Hewitt Electric Company, Hoboken, N. J., has received the commission of captain in the chemical section of the national army.

Messrs. OSTENBERG & CHRISTIANSEN, consulting chemical engineers of San Jose, Cal., have both taken up war work. Dr. Ostenberg has entered the Naval Flying Station at San Diego and Dr. Christiansen is a lieutenant on the medical staff of the navy.

MR. CURTIS PIGOTT, assistant superintendent of the Midvale plant of the United States Smelting, Refining and Mining Company, has resigned to become superintendent of the Herculaneum plant of the St. Joseph Lead Company, vice WILLIAM A. SMITH, resigned. Mr. Pigott was formerly connected with the Helena and Murray plants of the American Smelting and Refining Company, and is succeeded at Midvale by ROBERT WALLACE, metallurgist.

Messrs. J. L. SCHOELLKOPF, former president, and C. P. Hugo Schoellkopf, third vice-president, have withdrawn from the active management in the National Aniline & Chemical Co. They will continue as directors and stockholders. William J. Matheson was elected president. He is a director of the General Chemical Company, which is largely interested in the National Aniline Company. Dr. L. C. Jones of the Solvay Process Co. succeeds C. P. H. Schoellkopf as vice-president.

MR. R. C. SHUEY has been appointed assistant superintendent of Armour's Soap Works.

Dr. JULIUS STEIGLITZ, Mr. A. V. H. MORY and Mr. WILLIAM HOSKINS were the delegates of the American Chemical Society to the Congress of National Service, which was held in Chicago, February 21, 22 and 23. The congress was under the auspices of the National Security League.

Mr. W. L. TANNER, chief engineer of the Washoe plant of the Anaconda Copper Mining Company, has been transferred to Butte, where he will act as chief engineer of all the A. C. M. Co. operations in Montana.

Current Market Reports

Non-Ferrous Metal Market

Tuesday, March 26.—The markets for the most part have been quiet. Copper has been in good demand and tin continues scarce, with considerable demand. There has been plenty of lead offered and spelter has been considerably depressed in price.

Copper.—There has been a good demand for copper from consumers not engaged on government orders. Producers are not making large offerings, as a considerable part of their production is tied up until May and June. Prices remain as fixed by the government at 23.50 cents, producers' price, and 24.67½ cents, jobbers' price. Smelter production in January and February averaged 185,000,000 lb. monthly. Gains are expected in March and April.

Tin.—The tin situation continues very difficult. Straits tin is practically off the market, and such tin as can be brought brings fancy prices. As high as 85.50 cents has been paid for 99 per cent tin. Future Banca tin is quoted at 78.50 cents for April delivery. Chinese No. 1 is quoted at 77 cents for April delivery. There is reported to be 6300 tons afloat bound for this country, but arrivals have been slow and in small amounts for some time.

Lead.—Freer offerings have characterized the lead market during the past ten days. The trust price continues at 7¼c., New York. Independents asked 7¼c. to 7⅜c. A strike at the St. Joseph Lead Co.'s smelter at Herculaneum, Mo., on March 16, continued unsettled at the time of writing. There seems to be plenty of lead to take care of all requirements, but the demand continues strong and no impairment of the position of the market seems imminent.

Spelter.—In contrast to the other markets the spelter market has been dull and weak. Producers of spelter have had troubles of their own for such a long time due to overproduction that they would doubtless welcome price fixing by the government. Most producers are declining to quote at present prices, which are 7.30 to 7.55, New York, and 7.12½ to 7.25, St. Louis. The low prices may effect a decrease in production due to shutting down of some plants.

OTHER METALS

Aluminium, lb., 98-99 per cent. virgin, Gov't price	.321
Bismuth, lb.	2.50–2.75
Cadmium, lb.	1.50
Nickel, electrolytic, lb.	55.50
Silver, oz.	.92⅞
Platinum, oz.	108.00
Palladium, oz.	135.00–137.00
Cobalt, lb.	3.25–3.50
Magnesium, lb.	2.00
Quicksilver, Cal.	120.00
Quicksilver, Mexican.	115.00

The Iron and Steel Market

Shipments of finished steel products by mills continue to increase, but rather slowly. Traffic conditions on the railroads are still regarded as the limiting influence, but as time passes there is, almost insensibly, a change in the appearance of things, whereby it becomes doubtful whether this is the sole limiting influence. There is really a decided lack of pressure for deliveries on the part of some customers, and there is ground for suspicion that if shipping conditions enabled the mills to ship all their products at capacity they would be met by some customers with requests to curtail shipments. It is natural for mills to endeavor to place the best interpretation possible upon conditions, and to ascribe the curtailment in shipments wholly to traffic conditions is no more than natural, even though there may be other influences.

An outstanding feature of the market situation is that for the great majority of products there is practically no demand except that arising from the war. This, however, is not as indicative an item as might be supposed, for there is good reason to believe that the mills have on their books orders and contracts involving more than 12,000,000 tons of commercial steel, entirely apart from Government orders and orders from those who have Government orders to fill. That is a very large tonnage even for normal times, and when so much material is due to customers it is somewhat difficult to imagine who would be the customers who would

be anxious to buy large additional tonnages. In this connection it is important to bear in mind that owing to uncertainties of business as well as uncertainties of delivery, owing to the priority that must be given to war work, it is not the disposition of the trade, either buyers or sellers, to make engagements far ahead, as they frequently do in peace times. It was generally predicted, when the system of set Government prices was inaugurated late last September, that the trend would be strongly toward a clearing off of order books, the ultimate condition to be approached being one of almost hand-to-mouth buying in the case of everything except war material.

The genuineness of the contract business on books, how certain or uncertain it is to lead to specifications and actual shipping instructions, is very much in doubt. After an excited and advancing market the mills are always left with a large volume of contract business, not all of which is carried out, and at the present time the uncertainties are greater than is usual in such cases.

War Requirements

Indications as to the volume of war steel requirements are becoming somewhat more definite. The shipbuilding work is gradually getting into better form, and a rate of building 500,000 deadweight tonnage a month may be reached in the early fall, involving the consumption, altogether, of about 250,000 gross tons of steel per month, at least one-half of this being in the form of sheared plates. Even a much larger consumption would not tax the plate mills, however. In 1916 their output of sheared plates, ¼-inch and heavier, averaged a trifle more than 150,000 tons a month, and capacity is, or soon will be, close to 300,000 tons a month.

The car buying program, which will be arranged largely by the Railroad Administration, although the orders will be placed chiefly by individual roads, is being gotten into shape, with prospects that very nearly the full car building capacity of the country will be engaged. This, with locomotive building, may for a time absorb 300,000 to 400,000 tons of rolled steel, chiefly in the form of sheared and universal plates and structural shapes. An effort is being made to use universal plates to the fullest extent possible.

The shell steel program involves 2,500,000 tons for the second half of this year, against 1,500,000 tons ordered for delivery to the middle of next June, a small portion of the tonnage having been shipped in the closing months of last year.

At the moment there are large requirements for various construction items in connection with the war, including large tonnages of structural shapes and concrete reinforcing bars for docks and warehouses on both sides of the Atlantic, the object being to serve to the utmost the convenience of the ocean vessels, as well as the "port to front" road of the A. E. F. in France.

Iron and Steel Prices

At this writing there is no official information as to the decision of the War Industries Board as to what iron and steel prices shall rule after March 31, or how long the new prices, or the reaffirmed prices, are to be in force. Unofficial reports indicate that there will be some reductions, although nothing very extensive. There is ground for surmising, however, that a stronger effort will be made later by the Washington authorities for a somewhat lower level of prices. The present is rather an inauspicious time for argument in favor of price reductions, seeing that the mills have passed through a period of several months of exceptionally high costs, due to intermittent operations forced by the traffic situation. They are promised much better operations, but to date the improvement has not been sufficiently great or prolonged to be reflected in cost sheets, and thus it is largely in the form of promise. Two or three months hence the situation will be much clearer in this respect. Either operations will be on a much less abnormal basis or the promise of normal operations will be largely withdrawn.

Whatever the price limits established by the War Industries Board, there is a distinct probability that at times the maximum prices will be shaded as to some commodities, as it is evident that the dislocations produced by excessive war demands for certain materials on the one hand and greatly reduced peace or commercial requirements for other commodities on the other hand will cause some prices to be less firmly held than others. There will, in essence, be a reversal of the conditions obtaining in the first half of last year, when some commodities, such as plates, were in exceptionally great demand, and plate prices rose above their proper relation with prices for other commodities. Then all prices had a lower limit, based on the market value of semi-finished steel. Now all prices have an upper limit, that set by the Government. The former departures were above the normal average. Any departures in future will be departures downward.

Connellsville coke shipments have been steadily increasing and are now within about 10 per cent of the requirements of the furnaces depending upon Connellsville coke. Supplies of coal to by-product ovens are very nearly equal to requirements, and on the whole the production of pig iron promises to be ample for the requirements of steel mills, restricted as they still are to a considerable extent by inability to make shipments equal to their steel-making and steel-finishing capacity.

Plans are being completed for a thorough control of all the instrumentalities entering into the production and movement of Lake Superior iron ore in the coming season of lake navigation. Last season the effort was to secure maximum vessel movement, and this eventually congested the railroads serving Lake Erie ports. This year everything is to be made subservient to the railroad situation, so as to avoid congestion. The precise requirements of the blast furnaces will be ascertained, and no more ore will be brought down than will suffice them. The movement may be a trifle less than that of last year, as ore has accumulated while the blast furnaces were operating at much less than capacity.

Chemical Market

Coal Tar Products.—Trading was of slightly greater volume during the interval, although conditions continue to prevent large volumes of business from passing. The scarcity and high prices of some of the intermediates, coupled with the falling off in export trade, due to the disinclination of the authorities to issue licenses for many of the products, has considerable bearing upon the situation.

Benzol.—The large quantities offered on the market have caused a further reduction in price, and there is not a heavy demand even at present low prices.

Aniline Oil.—The position is slightly easier, due to the liberal offerings through second hands.

Beta Naphthol.—There has been a goodly volume of business passing in the technical grade, but offerings are sufficiently liberal, so that prices are unchanged.

Alpha Naphthylamine.—The demand has been heavier of late than for some time heretofore, and spot material is anything but plentiful.

Phenol.—There is not as great a demand as formerly and, though prices are quotably unchanged, the position is much easier.

Naphthalene.—Prices are well upheld, with offerings light and inquiries fairly plentiful.

Toluol.—Small quantities are offered on the open market, but the Government has commandeered such offerings as it is aware of, and it is unlikely that material will be offered liberally until the Government's needs are covered.

Aniline Salt.—Low offerings are a thing of the past, and producers are keeping the market well in hand.

Dimethylaniline.—Only a few producers are offering. The demand is fair and prices are slightly higher.

Paranitraniline.—Has been in heavy demand of late, and prices are higher, with offerings light.

Benzoate of Soda.—Is slightly easier, due to surplus offerings and light consuming demand.

Ortho Toluidine.—The scarcity of toluol has caused a curtailment in the production, and with an active demand prices have advanced.

Salicylic Acid.—Is offered liberally, and the demand is not heavy, so that it is possible to shade prices.

Para Nitro Phenol.—The production has increased, with

a slight falling off in consuming demand, and it is possible to shade prices.

HEAVY CHEMICALS.—Generally speaking, the markets for these products have been quite dull and lifeless during the past two weeks, and the tendency has been downward as regards values, but at the moment of writing a reaction has set in and in a number of instances an advance has been secured for a number of the important items.

Caustic Soda.—The lowest point that has been reached in months was recorded during the interval when spot 76 per cent solid caustic sold at 3.70. This situation was possibly due to the fact that shipments to this port have been unusually heavy of late and buyers have not appeared as rapidly as arrivals, in consequence of which there was a rather unusual amount of quick liquidation. Shipments from works have been maintained on a much higher parity than spot lots, and producers have never been inclined to meet the prices the second hand interests were establishing. At the moment of writing the market has assumed a very firm tone and there is considerable activity noted, with spot sales as high as 4.50 and producers quoting the same price from the works. There are rumors current of important developments that will tend to not only increase the output of caustic but of establishing a situation that will mean higher prices.

Soda Ash.—In sympathy with caustic the market slumped to a marked degree during the interval, and there were sales of spot rolling ash in bags as low as 2.50. The demand has been unimportant, but on the day this was written an important demand developed and there were sales at 2.75 and 2.80, with some sellers holding to 2.95 ex-store. Barrels have been strong, however, and important business has transpired at prices ranging from 3.15 to 3.25.

Bichromate of Soda.—The market has presented many ear-marks of manipulation, and there have been so many ups and downs during the fortnight that it has not been possible to record them. Sales have occurred at 24c., possibly 25c., but at the moment of writing spot material is available at 21½c., with May shipments at 20½c.

Bichromate of Potash.—Business has been dull, and minor transactions have occurred at prices ranging from 44c. to 45c.

Cyanide of Soda.—There has been no improvement noted and a domestic brand is available at 38c. to 40c., with the English material held at 35c. to 35½c.

Prussiate of Soda.—Considerable activity has been noted of late and sales have occurred at 37c., 37½c. and 38c. Sellers are now refusing to shade 38½c. and the prospects of a still higher market are bright.

Yellow Prussiate of Potash.—In common with most potassium compounds there is a weak market to report for this product. Spot offers have been as low as $1.20, although for shipment $1.22 and $1.25 is asked.

Formaldehyde.—Sales have occurred at 19¼c. but, in view of the fact that the important buying season is developing, sellers are firmer in their ideas and 19½c. is now asked.

Chlorate of Potash.—The market seems to have gone "bust." Spot stocks have accumulated to such an extent that a buyer can name his own price. Probably 1500 casks are available locally. While the nominal price is 40c. to 41c. for domestic business, sales have occurred at 32c., 34c. and 36c. A real buyer could possibly do 30c. for an important amount.

Chlorate of Soda.—In contrast the situation has been firm, and sales have occurred at 24c. and in some instances 25c.

Copper Sulphate. — While the situation is described as somewhat firmer, there are resales of standard brands at 9⅛c. to 9⅜c., and these depress the first-hand market, which is 9½c. Outside brands have sold at 8¾c. and 9c.

Sulphuric Acid.—Offerings have been more liberal, but are not abundant by any means. Acid in sellers' tanks works 66 degree brimstone is held at $42.00 and $44.00 drums. Some 60 degree brimstone acid has sold at $25.00 sellers' tanks works, with offers at $22.50 buyers' tanks works.

Muriatic Acid.—The situation has been quite firm, and there are important inquiries noted. For the 20 degree material 2¼c. is quoted, and for the 22 degree 2½c. cannot be shaded, with sales as high as 3c.

Nitric Acid.—Resale lots have depressed the market somewhat, and there have been offers at 8¾c., New York, for the 42 degree. Generally, however, producers will not shade 9c. Carboys continue scarce and restrict the movement.

Oleum.—There have also been more numerous offers of the 20 per cent oleum, and sellers have quoted $70.00 drums without finding a buyer. Earlier in the interval sales were reported at $72.50 and $75.00.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, MARCH 22, 1918

Acetic anhydride	lb.	1.35 — 1.50
Acetone, drums	lb.	Nominal
Acid, acetic, 28 per cent	lb.	.10 — .11
Acetic, 56 per cent	lb.	.12 — .12½
Acetic, glacial, 99½ per cent, carboys	lb.	.37 — .38
Boric, crystals	lb.	.13¼ — .14¼
Citric, crystals	lb.	.74½ — .75
Hydrochloric, C. P.	lb.	.08 — .08½
Hydrochloric, 20 deg.	lb	.02½ — .02¾
Hydrochloric, conc., 22 deg.	lb.	.02½ — 03
Hydrofluoric, 30 per cent, in barrels	lb.	.06 — .06¼
Lactic, 44 per cent	lb.	.13 — 15
Lactic, 22 per cent	lb.	.05½ — .06½
Nitric, 36 deg.	lb.	.08¼ — .08¾
Nitric, 42 deg.	lb.	.08¾ — .09
Oxalic, crystals	lb.	.44 — 45
Phosphoric, 47-50 per cent paste	lb.	.09 — 10
Phosphoric, ref. 50 per cent	lb.	.26 —
Picric	lb.	Nominal
Pyrogallic, resublimed	lb.	3.10 — 3 15
Sulphuric, 60 deg.	ton	25.00 — 27.50
Sulphuric, 66 deg.	ton	42.00 — 44 00
Sulphuric, oleum (Fuming), tank cars	ton	70.00 — 75.00
Tannic, U. S. P., bulk	lb.	1.30 — 1.35
Tartaric, crystals	lb.	.75 — .78
Tungstic, per lb. of W	lb.	1.80 — 1.90
Alcohol, sugar cane, 188 proof	gal.	4.93 — 4 95
Alcohol, wood, 95 per cent	gal.	1.35 — 1.38
Alcohol, denatured, 180 proof	gal.	.70 — 72
Alum, ammonia lump	lb.	.04 — .04¼
Alum, chrome ammonium	lb.	.18 — 19
Alum, chrome potassium	lb.	.19 — 20
Alum, chrome sodium	lb.	.12½ — .13
Alum, potash lump	lb.	.09 — .09½
Aluminum sulphate, technical	lb.	.01¾ — .02¼
Alumioium sulphate, iron free	lb.	.02¾ — .03¼
Ammonia aqua, 26 deg. carboys	lb.	.27 — .28
Ammonia, anhydrous	lb.	Nominal
Ammonium carbonate	lb.	.11 — .12
Ammonium nitrate	lb.	(Fixed price) .14
Ammonium, sulphate domestic	lb.	.07¾ — .08
Amyl acetate	gal.	5.00 — 5.25
Arsenic, white	lb.	.16¾ — .17¼
Arsenic, red	lb.	.65 — .70
Barium carbonate, 99 per cent	ton	80.00 — 90.00
Barium carbonate, 97-98 per cent	ton	65.00 — 67 00
Barium chloride	ton	65.00 — 85.00
Barium sulphate (Blanc Fixe, powder)	lb.	.03¾ — 04
Barium nitrate	lb.	.08½ — .11
Barium peroxide, basis 70 per ceot	lb.	.30 — .32
Bleaching powder, 35 per cent chlorine	lb.	.02¼ — .02½

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

THE ALPHANO HUMUS COMPANY, Boonton, N. J. Capital, $4,000,000. To engage in the manufacture of fertilizers. Incorporators: John N. Hoff, Boonton; Richard Sellers, Bellevue, Del., and James E. Mantee, Portland, Me.

AMERICAN ALLOY AND CHEMICAL CORPORATION. Capital stock, $1,000,000. Directors: J. L. Boyle, G. A. Green, G. H. Beesemeyler, F. L. Riley, B. J. Quinn, A. J. Morse, J. I. Stevens.

THE AMERICAN INDUSTRIAL ENGINEERING COMPANY is a new enterprise with offices in the Monadnock Block, 53 West Jackson Boulevard, Chicago, which is headed by L. W. Lauren, president, and L. H. Bergman, vice-president.

Mr. Lauren was formerly vice-president of the Reynolds Wire Co., of Dixon, Ill., and Mr. Bergman was until a short time ago fuel engineer for the Midvale Steel Co. of Philadelphia, Pa.

The company, which is incorporated, will make a specialty in wire mill equipment, pulverized fuel installation, furnace work and fuel economy.

THE AMERICAN RECLAIMING & REFINING COMPANY, Bayonne, N. J. Capital, $250,000. To engage in the refining and reclaiming of metals. Incorporators: Bernard Rubine, Charles and Harry B. Dembe, 19 West Twenty-seventh Street, Bayonne.

THE ANDERSON COUNTY MICA COMPANY, Anderson, S. C. Capital, $100,000. To develop mica properties in Anderson County. Incorporators: J. J. Fretwell, N. J. Fretwell, Jr., and Raymond Fretwell, all of Anderson.

THE ARIZONA BAGDAD COPPER COMPANY, Dover, Del. Capital, $1,750,000. To mine for copper. Incorporators: Edward C. Christensen, E. B. Brownson, and Frederick C. Hary, all of New York.

THE R. M. BAILEY COMPANY, Dover, Del. Capital, $50,000. To manufacture iron and steel products. Incorporators: Charles B. Bishop, S. H. Baynard, Jr., and A. M. Fox, Wilmington.

THE BLUE RIDGE PAINT & COLOR COMPANY, Allentown, Pa. Capital, $10,000. To manufacture paints, varnishes, etc. A. W. Thompson is the principal incorporator.

THE BUCYRUS TIRE & RUBBER COMPANY, Buffalo, N. Y. Capital, $200,000. To manufacture automobile tires, tubes, etc. Incorporators: C. O. Henderson, Philip H. Heater, Bucyrus, Ohio, and George C. Riley, Buffalo.

THE DAY CHEMICAL COMPANY, Chicago, Ill. Nominal capital, $5,000. To manufacture chemicals and allied products. Incorporators: James B. Day, Robert A. Levener, R. H. Clinton, and Hilgard B. Young, Chicago.

THE DINGLE-CLARK COMPANY has been organized with offices at 536 Engineers Building, Cleveland, Ohio. This corporation will handle a complete line of motors, transformers, controllers, turbo-gears, and are in a position to install electrical equipment for any size plant with complete technical and financial responsibility assured. Mr. Howard Dingle and Mr. W. W. Clark were up to February 1, respectively, district manager and assistant manager of the Crocker-Wheeler Company in Cleveland.

THE EDMANSON & BATES COMPANY, Buffalo, N. Y. Capital, $150,000. To manufacture chemicals, etc. Incorporators: B. W. Stuart, E. M. Fitzmorris, and J. L. Kinney, Buffalo.

THE GREAT WESTERN LEAD & ZINC COMPANY, Miami, Okla. Capital, $100,000. To mine for lead and zinc. Incorporators: M. B. Rook, Miami; Edward Kesler, Carter, and J. G. Wherry, Commerce, Okla.

THE HART GLASS MANUFACTURING COMPANY, Dunkirk, Ind. Capital, $300,000. To manufacture glass and glassware of various kinds. Incorporators: Francis H. May, Thomas F. and T. Francis Hart, Dunkirk.

THE IDAHO COPPER COMPANY, Chicago, Ill. Capital, $250,000. To engage in a general copper mining business. Incorporators: William C., William O. Rouss and James A. Crotty, Chicago.

THE INDEPENDENT CHEMICAL COMPANY, Dover, Del. Capital, $4,500,000. To manufacture chemicals and allied products. Incorporators: W. B. Walsh, Brooklyn; J. A. Lyon, New York, and V. Harris, Pelham Manor, N. Y.

THE JEFFERSON GRAPHITE COMPANY, Birmingham, Ala. Capital, $20,000. To engage in the production of graphite. Incorporators: George R. Sincix, L. B. Gunville, and M. Hughes, Birmingham.

THE JOHNSON CHEMICAL COMPANY, Raleigh, N. C. Capital, $200,000. To manufacture chemicals and kindred specialties. Incorporators: James I. Johnson, James I. Johnson, Jr., and J. W. Cross, Raleigh.

THE KENSINGTON BRASS FOUNDRY & MANUFACTURING COMPANY, Philadelphia, Pa. Capital, $50,000. To manufacture brass, iron, steel, etc. Incorporators: Thomas W. Moore, L. V. Gillian and J. D. Levy, all of Philadelphia.

THE KRAYER CHEMICAL COMPANY, Elizabeth, N. J. Capital, $50,000. To engage in the manufacture of chemicals. Incorporators: Dr. Stephen S. Krayer, A. Krayer, H. Jacobs and Clarence S. Myer, Elizabeth.

THE LIBERTY LEATHER COMPANY, Dover, Del. Capital, $100,000. To manufacture leather and leather products. Incorporators: M. L. Horty, F. D. Buck and K. E. Longfield, Wilmington.

THE L. N. N. FOUNDRY COMPANY, Cleveland, O. Capital, $20,000. To operate a general foundry business. Incorporators: H. H. Neuman and C. E. Lyall, Cleveland.

LOWE BROTHERS COMPANY, Springfield, Ill. Capital, $47,000. To manufacture paints, varnishes, etc. Houston Lowe is president.

THE LUCKEY LEW LEAD & ZINC MINING COMPANY, Tishomingo, Okla. Capital, $25,000. To mine for lead and zinc, etc. Incorporators: George W. Dudley, C. W. Burton, Tishomingo and J. J. McKanna, Joplin, Mo.

THE LUTZ COMPANY, INC., OF NEW JERSEY, Camden, N. J. Capital, $125,000. To operate a general foundry and machine shop. Incorporators: William H. Lutz, Samuel Mason and Joseph S. Pedrick, Camden.

Construction and Operation

Alabama

EUFAULA.—Fire, on March 10, destroyed the entire plant of the Eufaula Cotton Oil Company, with total loss estimated at $65,000. The entire equipment of crushing and other machinery was also totally destroyed. The company has plans under consideration for the immediate reconstruction of the plant.

FLORENCE. — Operations are being rushed in connection with the construction of the new Government nitrate plant at Muscle Shoals, and it is expected that the first unit of the works will be completed and ready for operation by June 1.

Arizona

HUMBOLDT.—The Consolidated Arizona Smelting Company has commenced the construction of four Wedge mechanical roasting furnaces, each 22½ feet in diameter, having seven hearths for roasting and one for drying, the furnaces to be equipped with individual Cottrell dust-precipitators. When the new furnaces are completed, the plant will have a capacity of 600 tons of wet charge per twenty-four hours, or 150 tons per furnace per twenty-four hours, producing a calcine containing 8 per cent sulphur. The company is planning ultimately to double the capacity of the entire plant.

Arkansas

COTTER.—The Dixie Girl Mining Company is planning for the immediate installation of new equipment at its lead and zinc producing plant, including tables, compressors and air drills, to increase the present capacity of the plant. A. C. Barnhart is superintendent.

SPYKER.—The Southern Carbon Company is considering the immediate installation of new gasoline-making machinery in its plants at Spyker and Fairbanks.

California

JACKSON.—The Fortuna Mining Company is planning for the construction of a new concentration mill at its plant. The company has commenced the erection of a new electric power line at its works near Belleview.

CORCORAN.—L. B. Dapron is considering plans for the construction of a new four-stand cotton gin at Corcoran and a smaller plant at Fresno.

BAY POINT.—The Pacific Electro-Metals Company is experimenting with electrodes, and when satisfactory results are accomplished the company will take steps toward building the second unit of this establishment.

HERCULES.—One of the largest plants in the United States for the manufacture of trinitrotoluene for the army and navy is to be erected at once as an addition to the plant of the Hercules Powder Company at Hercules, Cal., according to advices received from Washington by the San Francisco Chamber of Commerce. The construction work on the plant is to be started at once and rushed with all possible speed. According to Warren H. McBryde, assistant superintendent for the Hercules Company, approximately 2000 men and women will be employed in the new plant.

CRUCERO.—The Tecopa Mines Company is planning for the construction of a new smelter at its local plant. Plans are also under consideration for a smelter at Tecopa. L. D. Godshall, Los Angeles, is in charge.

KLAMATH FALLS.—The Klamath Iron & Steel Company, recently incorporated with a capital of $20,000, has recently acquired a tract of three lots on Elm and Spring Streets as a site for the construction of a new foundry and machine shops. Contracts for the new works have been awarded. R. D. Cartensen is president; J. P. Fitzpatrick is secretary-treasurer, and D. M. Hall is general manager.

LOS ANGELES.—The Baker Iron Works, North Broadway, is planning for the immediate construction of a new two-story addition to its plant to cost about $5,500. Plans for the structure have been filed.

SAN FRANCISCO. — The Independent Steel Mills of Pittsburgh, Pa., which control the Liberty Steel Products Company, the Pittsburgh Steel & Pressed Car Works, and other corporations, are reported to be considering a number of sites on San Francisco Bay for the erection of a large new steel plant. P. G. Buerk is representing the companies.

Colorado

LEADVILLE.—The Star Consolidated Mining Company is making rapid progress in the construction of its new 300-ton mill, and the first 100-ton unit of the plant has been completed. The new plant will dress ore from the large bodies of low-grade iron-manganese deposits on the company's properties.

NEDERLAND.—Organization plans have been completed by the Malmo Mining & Milling Company, and it is planned to install the necessary machinery at the company's holdings. C. E. Bradenburg heads the company.

CLIMAX.—The new mill being erected at Hurfehr's spur by the Molybdenum Products Company is being rushed to completion, and it is expected that the plant will be ready for operation at an early date. A. B. Scott is manager.

DENVER.—The Queen City Foundry Company, Denver, Col., has placed an order for a one-ton Booth-Hall electric steel furnace to replace the converter equipment now being used by that company. The furnace has a holding capacity of three-quarters to one ton, and is rated at 300 kva. Power will be delivered to the furnace by the Denver Gas and Electric Company.

PUEBLO.—The Norcross Chemical Company of Denver is constructing a sulphuric and nitric acid plant here. The Kalbperry Corporation of New York are the consulting and designing engineers.

Delaware

WILMINGTON.—The E. I. duPont de-Nemours Company is planning for the construction of a new shell-loading plant on property recently acquired at Dundalk, Md.

Georgia

ATLANTA. — The Hec Manufacturing Company, 82 Marietta Street, is planning to increase the capacity of its plant by the installation of new equipment, to be devoted to the production of steel, brass and copper specialties.

Illinois

CHICAGO.—The U. S. Reduction Company recently purchased a tract of land of about 600 acres in Colorado. The present plans are to erect a large aluminium factory on this site.

CHICAGO.—The J. Greenbaum Tanning Company has recently purchased property at the northeast corner of Elston and Warsaw Streets, about 100 x 120 feet, for a consideration of $12,000. The property adjoins the company's tannery, and it is planned to construct a large new addition, for increased capacity, at a cost of about $100,000.

EAST CHICAGO.—The Sinclair Oil Refining Company has inaugurated operations in its new local refinery, oil having reached that point from the company's Oklahoma and Kansas properties through the new pipe line recently completed.

Indiana

TERRE HAUTE.—Colonel Gooderham of Toronto, and Captain Burton, an English officer, composing a British mission on manufacture of explosives, were here recently letting contracts and arranging for the opening of the old Commercial distillery as a factory for making acetone, the chemical base of cordite, an explosive, and "dope" for airplane wings. This will be manufactured from corn. Priority shipment of special machinery has been assured, and it is believed manufacture will be started within a few weeks. The final transfer of the plant from the John Edward Beggs interests to the British government were completed in New York.

WABASH.—Oscar Frosell, a Swedish-German chemist, who has been doing governmental experimental work here for some time, announced today that he has succeeded in making the first American magnelith, a material used for the deck floors of battleships. The material has been given rigid tests and cannot be checked or cracked by bullets. Magnesite, a magnesium cement, the base from which magnelith is manufactured, was obtained from the Pacific coast.

Iowa

CEDAR RAPIDS.—The La Plant-Choate-Williams Company is planning for the establishment of a new department at its plant and will install a complete new foundry building for the production of steel castings, etc. A five-ton open hearth furnace will be installed for initial operations. J. S. Williams will be in charge of the casting production department.

OTTUMWA.—The plant of the Morey Clay Products Company was recently damaged by fire to the extent of $30,000.

Kansas

BAXTER.—The Aksarben Mining Company is planning for the construction of a new concentration mill on the Cooper properties, recently leased by the company. John Voohees is president.

BAXTER SPRINGS.—The N. S. Sherman Iron Works Corporation is planning for the immediate construction of a new foundry and machine shop, about 40 x 80 feet, and 150 x 150 feet, respectively, both one-story structures.

TREECE.—The Commonwealth Lead & Zinc Company is considering plans for the erection of a large new mill at its properties. Extensive development work has been in progress for some time, and a good deposit at 260 feet depth has been opened.

Kentucky

LEXINGTON.—The Southwestern Petroleum Company has recently secured oil lands in Clay, Chiles, and Miller, Lee County, located on Cave Fork, Bald Rock, and Sinking Creek, for a consideration said to be about $40,000, and is planning for extensive development work.

WHITESBURG.—The Indian Refining Company has completed plans for the laying of a new pipeline, four-inch, from its new oil territory in Powell County to Ravenna, on the Kentucky River, a distance of about thirty miles.

Louisiana

DONALDSONVILLE. — The Norman Planting Company, which recently acquired the Belle Alliance and Evan Hall sugar plantations, is said to be planning for the construction of new additions to the refinery to provide for increased capacity. A. W. Norman heads the company.

Maryland

BALTIMORE.—Plans have been prepared by the Western Maryland Railroad Company, Continental Building, for the erection of a new one-story shop addition at its wheel works at Hagerstown. The structure will be about 30 x 35 feet, and is estimated to cost $10,000.

PERRYVILLE.—The Atlas Powder Company has begun the construction of a $6,000,000 plant for the manufacture of nitrate of ammonia from sodium nitrate and ammonium sulphate, according to announcement. The company is acting for the government, and at the end of the war the government will take over the plant. The company has 2000 men at work constructing the foundation for the plant on the site at Perry Point farm, at the junction of the Susquehanna River and Chesapeake Bay, near Perryville, Md. The plans call for the plant's completion by July 1, and afterward 1000 hands will be employed in manufacturing the nitrate for use in making explosives.

Massachusetts

SPRINGFIELD. — The Smith Foundry Company is planning for the removal of its plant to Greenfield, and will increase the capacity of the plant by the installation of new equipment.

WEST SPRINGFIELD.—The Gilbert & Barker Manufacturing Company is making rapid progress in the construction of new additions to its plant, to cost about $80,000. The capacity of the power house is also being increased.

Michigan

DETROIT.—Fire recently destroyed the four-story plant of the Monarch Steel Castings Company, which was engaged upon war contracts, with total loss estimated at $350,000. A number of valuable patterns were also destroyed.

MIDLAND.—The government has taken over the Dow Chemical works at Mt. Pleasant and Midland and will advance $2,000,000 for enlargement and new equipment in order to adequately supply the chemicals needed in the manufacture of munitions.

Mr. Dow will continue in the management as now, but otherwise it will be conducted as a government industry. A large number of new wells are to be put down, as fast as possible, between Mt. Pleasant and Midland, a pipeline will be laid between the two plants and a big power plant built somewhere between the two cities, which will supply light and power the whole length of the line.

GRAND RAPIDS.—The Grand Rapids Varnish Company, which recently acquired property adjoining its plant on Godfrey Avenue, has had plans prepared for the construction of a new addition, about 40 x 60 feet, which will be used as an extension to its enamel manufacturing department.

HOUGHTON.—Plans are under consideration by the Seneca Mining Company, operating the Seneca mine, for the immediate reconstruction of its machine and forge shops, recently destroyed by fire.

MARQUETTE. — The Cleveland Cliff Iron Company, Cleveland, Ohio, has commenced the reconstruction of the local alcohol refinery of the Pioneer Iron Works, which it controls. This plant was recently destroyed by fire, and the new works are estimated to cost about $250,000.

Minnesota

DULUTH.—The Zenith Furnace Company has taken out a building permit for the construction of a new concrete and steel gas holder to have a capacity of 1,000,000 cubic feet. The estimated cost of the work is $135,000.

Missouri

SENECA. — The Wyandotte Zinc Company is considering plans for the immediate construction of a new concentrating plant at its properties.

ST. LOUIS.—The Monsanto Chemical Works, 1800 South Second Street, has recently acquired the plant of the Commercial Acid Company, East St. Louis, Ill., for a consideration said to be in the neighborhood of $2,000,000. The company recently increased its capitalization to $5,000,000 for this purpose. The plant of the Commercial company includes a site of 114 acres, with twenty-five factory buildings, machinery equipment, etc., and it is planned to continue the manufacture of sulphuric acid, nitrate acid, carbolic acid, etc.

ST. LOUIS.—The Engel Paper Box Specialty Company, 1906 Pine Street, is planning for the installation of new machinery for the manufacture of paper cans and tubes in connection with its present box-making plant. W. W. Stroop is secretary.

Montana

BANNACK.—C. W. Stalling has recently leased the Hendricks gold mine, and is considering the construction of a new 5-stamp mill.

Nebraska

OMAHA.—The Henry R. Gering Company has acquired property at 1114-16 Farnam Street, and will make alterations and improvements in the structures for the establishment of a new chemical manufacturing plant.

Nevada

BULLION. — William Patterson and J. D. McFarlane are planning for the construction of a new local smelter for the handling of ore produced in Bullion and vicinity. F. G. Buick is engineer.

JARBRIDGE.—The Elkoro Mines Company has inaugurated operations at its new 150-ton cyanide mill. The new plant is operated entirely by electricity, which is generated at Thousand Springs.

New Jersey

EAST NEWARK.—The Ohio Cities Gas Company has acquired the plant of the Pure Oil Company, about 105 x 330 feet, on Passaic Avenue, and about 5 acres of land on Passaic Avenue near the Lincoln Highway, Kearny Meadows. It is said the property will be used for extensions.

NEWARK.—The Maas & Waldstein Company, Avenue R, manufacturer of chemicals, has recently taken out a building permit for alterations at its plant. The company is also planning for the erection of a new addition to cost $12,000.

BAYONNE.—Fire, on March 18, destroyed one of the new high pressure tubular stills at the plant of the Tide Water Oil Company, with loss estimated at $70,000.

CAMDEN.—The R. M. Hollingshead Company, manufacturer of oils, greases, etc., has taken out a building permit for the construction of a new brick addition to be located at Ninth and Market Streets.

BELLEVILLE.—The Lloyd Chemical Works, with plant in Holmes Street, is planning to purchase the site formerly owned by the Kent Motors Corporation, covering about 16 acres, from Washington Avenue to the Passaic River. It is understood that a large new chemical manufacturing plant will be erected by the company, comprising several three-story brick structures, to facilitate the handling of a $40,000,000 Government contract which the company holds. An expenditure of approximately $2,000,000 will be involved in the project.

WHARTON.—The Wharton Steel Company's iron ore mines, which consist of three mines—Scrub Oak, Oreland and Andover, have just been connected up. To connect these mines it was necessary to build six miles of 33,000 volt lines and one mile of 11,000 volt lines.

The Wharton Steel Company expects these mines to turn out about 2,000 tons of ore per day, which will take care of their furnaces at Wharton. The Steel Company owns the ore mines and also the railroad running from the mines to the furnaces. The mines run around 45 per cent before being concentrated and after being concentrated run about 65 per cent. At the present time The Wharton Steel Company is selling pig iron to the Bethlehem Steel Company and the Italian Government.

New York

OLEAN. — The chemical plants in this vicinity conducted for the distillation of hardwood have had their products acetate of lime and acetone, commandeered by the war department. The following plants are in this section: Vandalia Chemical Company, Straight Creek Chemical Company, Susquehanna Chemical Company, Lacka-

wanna Chemical Company, Keystone Wood Products Company, Smethport Wood Products Company, Corryville Chemical Company, Newton Chemical Company, Heinemann Chemical Company, Norweich Chemical Company, Smith Chemical Company, Minard Run Chemical Company, Lewis Run Chemical Company, and Custer City Chemical Company. Nearly all of these concerns have their main offices in Olean.

The 14 concerns, named above, employ 1000 at their plants and, in addition, at this season of the year keep 4000 men as teamsters and wood cutters, busy in the woods supplying chemical wood. The acetone produced by these concerns is largely used in the manufacture of high explosives, being indispensable for certain processes.

ALBANY.—A chemical plant costing $1,000,000 is to be constructed by the Federal Government at Mechanicsville to utilize the by-products of paper manufacturing plants of the West Virginia Pulp and Paper Company. The Government is to manufacture acetone, which is to be used to mix with varnish for coating airplane wings.

NEW YORK.—The Central Smelting & Refining Company, 220 Rider Avenue, is said to be planning for extension to its plant on property recently acquired on Third Street, Long Island City, about 75x150 feet.

YONKERS.—Fries & Fries, Cincinnati, Ohio, manufacturers of chemicals, etc., have acquired property comprising about one and one-half acres from Woodworth Avenue to the New York Central Railroad, to be used for the manufacture of waterproof coatings, syrups, etc.

LONG ISLAND CITY.—Plans have been filed by the Pittsburgh Plate Glass Company, for the construction of its proposed new two-story plant, about 265 x 270 feet, on Hunters Point Avenue. The structure will contain about 102,000 square feet, and is estimated to cost $200,000.

SYRACUSE.—The Savage Arms Corporation is considering the erection of a large addition to its plant to increase the present capacity by approximately 5000 machine guns per month. It is said that the company has Government contracts on hand at the present time which will occupy practically all of 1918

Ohio

MOUNT GILEAD.—The extensive new buildings of The Hydraulic Press Mfg. Company at Mount Gilead, Ohio, are now occupied and the plant is again in operation to its full capacity. The new equipment represents the most advanced types of metal working machinery available and is specially adapted for the building of hydraulic presses, pumps and valves.

CINCINNATI.—The Troy Metal Products Company, recently incorporated with a capital of $200,000, is negotiating with the Huenefeld Company, Spring Grove Avenue and Straight Street, for the occupation of the latter's plant to engage in the manufacture of munitions.

CARTHAGE.—The Pollak Steel Company is planning for the construction of a large new plant, to be devoted to the manufacture of equipment for torpedo destroyers. The new works are estimated to cost about $500,000, and will give employment to about 1000 hands.

CLEVELAND.—The Aetna Steel Castings Company has awarded a contract for the construction of a new foundry building, about 100 x 165 feet, at 2284 Scranton Road, Southwest, to cost $15,000.

COLUMBUS.—The Atlas Brass Foundry Company, 980 South Park Street, manufacturer of brass, bronze, and aluminum castings, and screw machine products, has taken bids for the construction of a new three-story brick addition, about 40 x 65 feet.

TOLEDO.—The Toledo Electric Steel Company, manufacturer of high speed and special alloy steels, is planning for the erection of a new steel mill building to increase the capacity of the plant. A 12-inch three-high tool steel bar rolling mill with drive, three water-tube boilers, 3-ton electric furnace, and 5, 3, 2 and 1-ton hammers will be installed.

Oklahoma

PICHER.—The Southwestern Missouri Mining Company is considering plans for the construction of a new 500-ton concentrating plant on its 40-acre lease of zinc properties between Picher and Treece, Kan.

QUAPAW.—The Kentex Mining Company is planning for the construction of a new mining and milling plant at its properties, to cost about $100,000. S. C. Kennedy is manager.

QUAPAW.—The Bethlehem Zinc Company is considering the erection of a new mill at its properties. T. Wade is president.

QUAPAW.—The Lucky Joe Mining Company has commenced the construction of a new 250-ton concentration plant at its lead and zinc properties. J. P. Matthews is manager.

Oregon

GOLD HILL.—O. C. Runnals, Seattle, Wash., and associates, have acquired the Utah Mining Properties, located about twelve miles from Gold Hill, and are planning the erection of an electric transmission line, about five miles long, to connect with the lines of the California-Oregon Power Company. It is proposed to equip the mines with electrically operated machinery.

Pennsylvania

PHILADELPHIA.—The Gorgas-Pierie Company, 126 East Allen Street, manufacturer of seed oils, etc., has awarded a contract to the Turner Concrete Steel Company, 1713 Sansom Street, for the construction of a new two-story brick and concrete addition, about 55 x 75 feet, to cost $15,000.

PITTSBURGH.—The plant of the Walker-Stratman Company, Herrs Island, near Pittsburgh, was destroyed by fire on March 8. The company was engaged in the manufacture of glycerin for Government use in high explosives.

RITTERSVILLE.—The Noequa Chemical Company, recently incorporated in Philadelphia with a capital of $450,000, is considering the construction of a large local manufacturing plant.

TYRONE.—The West Virginia Pulp & Paper Company has commenced the construction of its proposed new local plant, comprising eight manufacturing buildings. The new works are estimated to cost $500,000. The George A. Fuller Company, 949 Broadway, New York, is the contractor.

NEW CASTLE.—A nitric acid plant costing $1,000,000 will be erected as an addition to the Covert's station powder plant of the Grasselli Chemical Co. Construction work has already started.

SCRANTON.—The American Color Company, which is constructing a $50,000 plant at Scranton, Pa., will begin the manufacture of direct cotton colors about April 1. Benj. C. Warnick is president, Clifford Stone Cooley, vice-president and general manager, and E. B. Jermyn, treasurer

Tennessee

COLLINWOOD.—The Government is building a large wood chemical plant in Collinwood to procure acetate of lime and wood alcohol for munitions. Collinwood is located in the center of Wayne County, and the center of a wilderness of timber. Contract for the plant was made with the Tennessee Valley Iron and Railroad Company, a Pittsburgh concern, which owns 90,000 acres of land in this county, and which will operate the plant for the Government. The plant is to cost $2,000,000 and be completed in eight months. Thompson-Starrett Company of New York will erect the plant. This will be the largest plant of its kind in the world and will use 200 cords of wood a day.

The Government will require all the products except the charcoal which will be used in the manufacture of pig iron.

DUCKTOWN.—The Tennessee Copper Company, 11 Broadway, New York, is planning to increase the capacity of its local sulphuric acid plant to 3,000,000 tons annually.

MEMPHIS.—The Webster-Warnock Chemical Company is having plans prepared for the reconstruction of its chemical manufacturing plant recently destroyed by fire with loss estimated at $25,000.

HADLEY'S BEND.—The United States Government, War Department, is planning to have a daily capacity of 1,000,000 pounds of smokeless powder and 1,000,000 pounds of guncotton at its new local explosives plant, which will represent an expenditure of $100,000,000 instead of $60,000,000 as previously announced. The duPont Co. has charge of the construction work.

KINGSPORT.—Information has been received of the location of an alcohol plant at Kingsport, Tenn. The Government is behind the enterprise which, when completed will cost $1,250,000, and will give employment to a thousand men. It is understood that the product of the plant will be used for polishing gunstocks for which maple and beech lumber is used. The by-product will be converted into charcoal which has a ready market at the time. Already 35 acres of land have been secured and work will go forward at once.

Texas

BROWNWOOD.—Rapid progress is being made by the Gotebo Oil, Gas & Refinery Company in the construction of its new local refinery, and it is expected that the plant will be in operation at an early date.

BROWNWOOD.—The Brown-Ard Refining Company, Ardmore, is considering the construction of a large new oil refinery on a tract of land comprising 26 acres on the Hall property west of Brownwood. The new plant will have an initial capacity of about 1,000 barrels daily.

ROCKDALE.—Henry M. Butler, Hillsboro, and associates, have completed arrangements for the development of a large bed of lignite recently purchased, near Rockdale. It is planned to mine the fuel by means of steam shovels.

Utah

SALT LAKE CITY.—The Western Silver Mines Company, operating in Mineral County, Nevada, has announced that plans have been completed for the construction of the first unit of its proposed 500-ton concentrating mill at its properties. The holdings of the company consist of ten claims and a mill site, aggregating 220 acres, the ore consisting of a highly siliceous vein material carrying values in gold, silver and lead. A. L. Jameson, of Los Angeles, Cal., is president.

SPRINGVILLE.—The Springville-Mapleton Sugar Company has commenced the construction of its new local sugar refinery.

OGDEN.—The Ogden Portland Cement Company, operating the plant at Baker, Utah, twenty-five miles north of this city, will manufacture potash, if the results of the experiments now being made prove satisfactory. This is the announcement made at the offices of the company, here. The experiments are being conducted at the plant by Manager H. C. Day and chemical experts have been brought here from California, probably from the Western Precipitation Co., of Los Angeles, who install the Cottrell process.

Virginia

NORFOLK.—The Linde Air Products Company, New York, is planning for the construction of a new local plant to cost about $50,000.

NORFOLK.—The Vithumus Corporation is having plans prepared for the construction of a new plant for the manufacture of fertilizer at South Norfolk.

PORTSMOUTH.—The Portsmouth Cotton Oil Refining Corporation, which recently increased its capital from $650,000 to $1,000,000, has awarded a contract to Nichols & Linderman, Seaboard Bank Building, Norfolk, for the construction of a new two-story factory building, about 100 x 150 feet, to cost $30 000.

STAR TANNERY.—The Mineral Ridge Manganese Corporation, recently incorporated with a capital of $250,000, has commenced the development of its 700-acre tract recently acquired. At the present time the company has a daily capacity of 20 tons of manganese, which it is planning to increase to 60 tons. W. B Shaffer, Nazareth, Pa., is president.

Washington

BELLINGHAM.—The Boundary Red Mountain Mining Company is planning for the immediate reconstruction of its power plant recently destroyed by fire. It is expected that the new plant will be ready for operation during the coming fall

LOON LAKE.—The Loon Lake Copper Company is planning for a bond issue of $40,000 to provide for the construction of a new mill, including flotation and grinding machines.

OROVILLE.—The Hudson Consolidated Mines Company has had plans prepared for the construction of a new 150-ton ball mill and flotation plant at its properties. Estimated cost of the structure is $75,000.

SPOKANE.—The Rhodes Harvester Company has had plans prepared for the immediate construction of a new foundry addition, about 60 x 100 feet, to its plant to cost about $10,000. The company is also planning for extensive improvements to increase the present capacity.

Copper in Converter Slags

THE tourist with metallurgical proclivities visiting the copper smelters in the Rocky Mountain region is struck by a very general similarity in most of their machinery and methods. This doubtless is a result of the evolutionary development of copper metallurgy during the last twenty years. Take, as an instance, the roasting department. It utilizes a furnace which is essentially a steel tank containing multiple superimposed hearths through which the ore is rabbled by cooled arms fixed to a rotating central shaft. Of course many variations in detail design may be noted, and the furnaces may therefore variously be called McDougall, Wedge, or Herreshoff. Furthermore, differences appear in methods of charging ore, removing calcine and handling smoke in adaptation to the general requirements of the plant and its surroundings. Still it is apparent that this type has exclusively supplanted the earlier heaps, stalls, straight-line and curved hearths, sintering pots and Brückner cylinders as a roaster for copper ores.

The great variation in the methods of handling converter slag is consequently quite suggestive of the diversity of opinion which prevails on this subject, and indicates that some, if not many, of the solutions have an insecure foundation on financial economy and metallurgical fact. Probably based on the idea, implied if not admitted, that the copper in these slags is held in complex compounds which cannot be broken up in the approximately neutral reverberatory furnace, many plants allow the slag to solidify and resmelt it in a blast furnace. The accompanying slag-casting machine may be a series of stationary or tilting pans, a chain of molds traveling in a straight line or about a "merry-go-round," or again the slag may be poured out in a thin layer on an ore bed, or even into a sump or a hole in the ground to be reclaimed later by steam-shovel or grab-bucket. If the plant possess no blast furnaces, or the management is willing to brave slag loss to save coke, the slag is charged into reverberatories. Here again considerable variation is noted; cars may be switched to the charging track and the liquid slag poured through the furnace roof with the maximum fall possible; pots may be poured by cranes into slag launders delivering the slag through the side or back wall at a moderate head, or finally cold skulls may even be used for "manger" filling.

After noting this diverse practice, it is not surprising to find little real information available on the fundamental question "How is the copper held in the converter slag?" or the broader one "How is copper held in a furnace slag?" If the intense oxidizing atmosphere in the converter forms copper oxides and silicates, then doubtless a powerful smelting process would be needed

for its retreatment, and hot-charging into the reverberatory would merely dilute the slag loss. However, Laney of the United States Geological Survey found after microscopic investigation that the valuable metal even in good furnace slag is mostly in a suspension of minute spheres of matte; on this basis the whole question of recovery becomes merely one of "hindered settling" wherein the relative specific gravities of the matte and slag, the size of the particles of matte, but more especially the viscosity of the slag itself play their separate roles.

Converter slags can be run so high in magnetite as to be unworkably sticky. If the viscosity of furnace slag is similarly affected by a more modest increase in the iron content the contention of the metallurgists at the El Paso plant is easily explainable, that in a reverberatory furnace a low-iron slag will be low in copper, whether or not converter slag is charged. Again, Green's idea that converter slag should be poured into a bath from a considerable head is justified, since the large body of matte would tend to wash out the smaller particles by actual physical contact. Lastly, good recovery might be effected by mere settlement, if sufficient time be given at a temperature high enough to maintain a mobile melt. Whether this final alternative is economically possible is a question of such importance as to warrant a considerable expenditure in research. In any event, it would seem that a study of the relation of iron content and temperature to the viscosity of a molten slag would pave the way toward a proper understanding of many furnace problems, as well as to a rational solution of the ever more pressing and vexing question of the proper elimination of iron from the smelting system.

Fats From Petroleum

"WHY," asked the Italian savant, Professor Giacomo Ciamician, "should we use only the fossil energy of the sun?" Why drill for oil and run it through pipe lines and distill it and chlorinate and oxidize and reduce and worry and fret over making fatty acids out of it, when their glycerides are already made for us over beautiful, waving fields of corn and soya beans and on tropic sands in cocoanuts,—not to mention only a few of the rich sources of supply now at hand?

Nature's chemistry book is planned on different lines from ours. She does not bother about the elements as much as we do. She regards the elements as a sort of cosmic underwear and elemental stuff is displayed only occasionally. In natural synthesis the units are seldom elemental. Nature also has physical chemistry in the back of her head and she uses it as we use the multiplication table, without counting her fingers. It is the same with the phase rule, and again she has mathematics enough and all by heart to meet any number of phases. Then she applies the rule to men and women, to our utter confusion. In technology she introduces the element of aesthetics and makes her chemical factories, which are forests and fields, things of unspeakable beauty. Usually we hide our chemical factories as much as we can so that the least number of people may see them, which is entirely right and proper—since they look as they do. Again, Nature will not endure a stink, permanently. We make them and live in them.

It seems more than likely that even if peace ever comes again, the edible fats of mankind will be of vegetable rather than animal origin. It stands to reason that fats from soya beans and from other vegetal sources are more economically produced than by feeding corn to hogs and then killing the hogs. It even seems more economical to press seeds than to buy industrial reagents and then to burn trainloads of coal to recover them.

The greatest advances that have been made of late in the development of vegetable oils for human consumption have been with cocoanut oil, of which the imports into this country increased from 64,349,308 pound in 1916 to 163,091,004 in 1917. The soya bean industry is promising and peanut oil is here to stay. Cottonseed oil has long been a great American institution and corn oil is another aspirant for high office in human economics.

So, while we would not stay the hand of any one engaged in legitimate research, we have our favorites for encouragement. Just now we should like to see greater encouragement and interest in the work of biological chemists. Someone has computed that the application of the inventions of Louis Pasteur to industry produced in three years sufficient wealth to pay the indemnity demanded by Germany of France after the Franco-Prussian war. Biological chemists produce the real labor-saving inventions. With their yeasts and ferments and miscroscopic critters they train vast armies to work for us. It takes time to eliminate the unfit and to train the fit; but they work beautifully when they are started right. We have inherited ethyl alcohol by this process, but it looks as though acetone also were coming along pretty fast, and on a big commercial scale at that. These methods may give us glycerol some day, too, but as for the glycerides with the complex fatty acids the work is already done for us by the sun in the air. There is no reason to be satisfied with things as they are, but there is every reason to be appreciative, whenever we can. That is the cheerful philosophy of research.

A Program for Harmony

THE past two weeks have been eventful in developing plans for harmonious relations between employer and employee and fostering the spirit of the square deal in industry. As reported in detail on another page the War Labor Conference Board, appointed last January at the instance of Secretary of Labor Wilson, has recommended the creaton of a National War Labor Board to settle by mediation and conciliation controversies arising between employers and employees in fields of production necessary for the effective conduct of the war. By proclamation of the President the National War Labor Board has since been appointed, and all interested parties are urged by him to use the means thus provided for the adjustment of industrial disputes.

Undoubtedly quickened by a sense of national peril, and realizing the necessity of unity in purpose and action, representatives of the two great groups comprising our industrial life have sought and agreed upon a basis for understanding during the war. Accepted

in principle by recognized leaders, there remains the more important problem of securing the active approval and sincere co-operation of the interested parties when occasion arises to test their professions. We have confidence that, in the main, the machinery provided in the Board will be effective and that it will not only contribute to industrial peace and harmony during the war but prove a large factor in all future relations between industry and workers. Primarily a fruit of war, the plan should be found effective as an agency for peace.

We may, however, regard one thing as certain. Public opinion is not going to be lenient with either party to the agreement who may violate its letter or spirit. The plan and purpose of the movement are sufficiently well defined to make it possible to place responsibility for broken pledges, and the public memory is likely to be more retentive than usual when it comes to remembering those who deliberately or tacitly impede the progress of the war by strikes or lockouts. Conciliation and mediation are the order of the day.

Another straw indicating the direction of the industrial wind, is the announcement of the plan for industrial representation of the employees in the Standard Oil Co. of New Jersey. Workers elected for the purpose by their fellows met and dined with high executives—captains of labor with captains of industry, as one engineer has put it—and plans of mutual interest were talked about and launched. Considering the success which a similar plan has met in the Colorado Fuel and Iron Co., controlled by the same interests, the New Jersey company may justly anticipate harmonious relations with its men.

The Steel Corporation

THE annual report of the United States Steel Corporation is issued for 1917 in its usual comprehensive form. The corporation's production of pig iron was 15,652,928 tons while the production of ingots was 20,285,061 tons. In both items there were decreases from 1916 to 1917, while the production by independents increased. The corporation's pig-iron production decreased about 2,000,000 tons, while the production in the industry as a whole decreased only 800,000 tons, showing that the independent production increased 1,200,000 tons while the corporation production decreased 2,000,000 tons. This divergence was due to the shortage of coke, which was experienced with particular severity by the Steel Corporation. No coke ovens were operated at capacity in 1917, and as the independents has made greater additions to capacity than had the corporation they had an advantage. The corporation resolutely refused to buy coke in the market, when the market was already crowded with buyers.

The above is the statistical explanation, the commercial explanation involving certain important details. The corporation had planned for larger coke-making capacity, but the difficulty of maintaining construction schedules was too great even for the Steel Corporation. An addition of 140 ovens has recently been completed at Gary, and there are now nearing completion, scheduled for at least partial operation by July 1, 640 ovens at Clairton, 208 at Lorain and 180 at Cleveland, making a total of 1,168 ovens, which are good for about 5,000,000 net tons of coke a year.

When the complete statistics of the American Iron and Steel Institute are compiled for 1917 they will show the coke consumption per ton of pig iron of all the blast furnaces, and beyond doubt an enormous waste of coke will be shown, caused by intermittent supplies and resultant bankings or slow operation. Even in the case of the Steel Corporation, which has large furnace groups and can manipulate its coke supplies to particular advantage—all its coke for use beyond Pittsburgh being consigned to the Conway yard for later routing—the coke consumption appears to have increased from 2,145 pounds in 1916 to 2,230 pounds in 1917.

An evidence of the effect of successive wage advances in the steel industry is furnished by the data given in the Corporation's report. There were three 10 per cent wage advances in 1916 and two 10 per cent advances in 1917. In 1913 the average salary or wage per day of all employees except general administrative and selling force was $2.85 a day. In 1917 the item had risen to $4.10, the 10 per cent wage advance of May 1 having operated for seven months and that of October 1 for only three months, while this month a 15 per cent advance goes into effect. From this it may be estimated that wages to be paid in future will average about 85 per cent above the average of 1913, the year before the war. Those wages were 50 to 60 per cent higher than wages obtaining in 1898. It is not only interesting, but important from a sociological and economic viewpoint, to note that in the latest wage advances the Steel Corporation has been the leader not only in form but actually in substance. The independents would not have initiated a wage advance this month, and some of them have criticized the advance which becomes general through the Steel Corporation's initiative.

The earnings the Steel Corporation reports for 1917 are $295,869,292, after paying interest on bonds of subsidiary companies, but before making allowance for bond sinking funds, depreciation, corporation bond interest, etc. This compares with $33,574,178 in 1916, the record year. This is the item that interests the shareholders, but the iron and steel manufacturing industry is interested in the total profits, before deduction of the Federal war taxes, as those are the earnings the mills and furnaces really made. It may be an incident of war that there was so large a margin between cost and selling price, but it is also an incident of war that the war taxes are levied. In the Corporation report as usually made all the taxes paid are stated in a lump sum, including municipal, county, state, etc. For 1916 this lump sum was $26,599,721. In the 1917 report the Federal taxes for 1916 are mentioned separately as having been $9,692,009, while for 1917 they were $231,465,435. This sum may be changed somewhat when adjustments are made with the Treasury Department. Comparison of the earning power of the plants may be made by adding Federal taxes to the reported earnings, this addition showing total profits of $343,266,787 for 1916 and $528,757,615 for 1917. These amounts are strictly comparable, being for each year the profits less all taxes but Federal, and less subsidiary company bond interest. The sums are subject to Federal taxes, bond sinking fund allowances, depreciation and similar items.

Readers' Views and Comments

Fats and Fatty Acids from Petroleum

To the Editor of Metallurgical & Chemical Engineering

SIR:—I believe the recent article by Dr. Gustave Egloff in METALLURGICAL & CHEMICAL ENGINEERING on the Snythesis of Fatty Acids from Petroleum merits some comment. To any one who has not had any experience in the synthesis or attempted synthesis of fatty acids and other derivatives from petroleum hydrocarbons, Dr. Egloff's article is somewhat misleading in its rather superlative optimism. There certainly is nothing in any work thus far published which would, by any stretch of imagination, warrant the statement that Germany may be feeding her population with synthetic fats made from petroleum.

The excellence of some of Dr. Egloff's previous articles might perhaps give the weight of authority to his statements on the fatty acid question, and I therefore feel that it should be pointed out that many of the claims made by authors quoted by Dr. Egloff are very far from good Anglo-Saxon truth. Perhaps the most prominent and most curious reference cited by Dr. Egloff is the work of Zelinsky. Zelinsky claims to have made fatty acids from petroleum hydrocarbons by preparing the Grignard magnesium complex of certain halogen derivatives of petroleum oils and reacting upon this with carbon dioxide. It is no reflection upon Dr. Egloff that he should have taken Zelinsky's work at its face value, but I suggest that any one interested may readily convince himself of the pure nonsense of commercial synthesis by this route by merely repeating, or attempting to repeat, Zelinsky's work. He will find that the yields are vanishingly small. The reasons for this are several, principal among which are the following:

1. The formation of the magnesium complex is exceedingly slow with derivatives containing more than eight or ten carbon atoms.

2. It is well known that the higher magnesium alkyl halides readily react with a second molecule of the original alkyl halide to give a hydrocarbon and magnesium halide. For example,

$$C_7H_{15}MgBr + C_7H_{15}Br \longrightarrow C_{14}H_{30} + MgBr_2$$

3. The halogen derivatives of petroleum hydrocarbons of ten to twenty or more carbon atoms are unstable and slowly break down on standing at room temperature to give free halogen acids and hydrocarbons which appear to be mainly saturated ring compounds. This behavior has not been published in any detail and I can cite no authority other than my own experience.

4. Stadnikoff in a series of comparatively recent papers showed that the alkyl magnesium halide and ether complex breaks down in a variety of ways. For example, Stadnikoff showed that a complex made from magnesium propyl iodide, carbon dioxide, and benzhydrylbutyl ether yielded a mixture of several hydrocarbons, free carbon dioxide and mixed ethers, only a trace of acid being obtained. He therefore states that the evidence gathered from a series of such studies points to the Grignard constitution rather than that of Baeyer, and suggests that the constitution of the compounds formed by passing in carbon dioxide is of the following type:

$$(C_6H_5)_2CH \atop C_4H_9 > O < \begin{matrix} C_3H_7 \\ CO_2MgBr \end{matrix}$$

There are obviously many other lines of attack, but I wish merely to point out that the methods so far disclosed are of practically no value for the purpose of making fatty acids from petroleum, even for the purposes of laboratory research, let alone commercial synthesis. For example, it is known that fusion of the higher alcohols with caustic potash yields free hydrogen and fatty acids, but only the higher primary alcohols give good yields. The secondary alcohols are very slightly oxidized under these conditions and yield mostly condensation products. The higher tertiary alcohols break down, giving acids of less number of carbon atoms. Also it has been shown that the alcoholates of the higher alcohols react with carbon monoxide under high pressures, but the principal products formed are esters of formic acid and not the higher fatty acids. The known methods for preparing alcohols direct from petroleum olefines yield only secondary and tertiary alcohols. Also no methods for adding halogens or halogen acids to the saturated or unsaturated hydrocarbons are known which give high yields of primary derivatives.

It is true that numerous methods have been proposed for oxidizing saturated and unsaturated hydrocarbons by air in the presence of various other substances and a great many wet methods have been tried, but the sum total of the results thus attained may be briefly summarized with the statement that in general the results are carbon dioxide, water, resinous or asphaltic material, and traces of the simple fatty acids such as acetic, propionic, butyric acids, etc., which usually have not been obtained in quantities sufficient for positive identification.

It cannot be too strongly emphasized that the chemistry of the aliphatic hydrocarbons is practically limited to methane, ethane, propane, butane and pentane and their derivatives. We then skip to a large island of knowledge which includes the chemistry of the terpenes and the reason for the rich development of this latter field is doubtless the ready availability of raw materials found in natural products—the essential oils. The books usually discuss the chemistry of the simple compounds, such as ethyl alcohol, ethyl bromide, ethyl cyanide, ethyl amine, butyric acid, fusel oil, etc., and then stop, usually with the added statement that the reactions presented for these simple derivatives are type reactions which hold good through the rest of the series. It would require more space even to indicate that this is not so than would be warranted in this brief note. Personally I believe that reactions which do not give yields of more than 2 or 3 per cent of the theory should *not* be inflicted upon the unsuspecting student as type reactions.

Our chemistry of the aliphatic series is decidedly spotty. We have a well rounded terpene chemistry,

a beautiful sugar chemistry, a complex chemistry of the fatty acids, and well perfected industrial methods, etc., but thus far the chemistry of the petroleum hydrocarbons brings up the tail end of the procession. Curiously enough the great bulk of the hydrocarbon chemistry which will go far in serving as a basis of exact chemical knowledge of petroleum has been done in Russia, although our own country has been blessed, as no other continent, with its rich petroleum resources. Personally I share Dr. Egloff's optimism to the point of believing that the commercial synthesis of fatty acids from petroleum *may* some day be accomplished, but not by the methods of synthesis now known and not until we have built up a much more extensive and quantitative knowledge of the behavior of hydrocarbons, such as constitute petroleum oils.

BENJAMIN T. BROOKS.

Flushing, N. Y.

* * *

To the Editor of Metallurgical & Chemical Engineering

SIR:—I am so much impressed with the value of the information conveyed in the paper entitled "Fats and Fatty Acids from Petroleum," printed in your issue of March 15, that I cannot refrain from expressing my appreciation and my hope that the authors will, before long, be able to present the results of their further work along the lines indicated in a later paper.

While I am not sufficiently well versed in the intricate combinations of carbon and hydrogen molecules to follow intelligently all the reactions involved and given in this new line of research, I have long been impressed with a belief, amounting to conviction, that, sooner or later, the problem of transforming and converting petroleum hydrocarbons into fats and fatty acids would be solved. The earliest patents mentioned by the authors for methods of this nature date back to 1912, but doubtless long before that time the subject had occupied the minds of chemists, for the prize is a most tempting one.

In a brief paper which I had the honor of presenting before the American Society for Testing Materials at its convention in June, 1911, on "A Novel Method of Detecting Mineral Oil and Resin Oil in Other Oils" (see Vol. XI, 1911), I said:

"Chemists will, I believe, eventually solve the problem that has hitherto baffled all their endeavors, of oxidizing hydrocarbon or mineral oils and of rendering them saponifiable. The monetary value of such a discovery is incalculable and the solver of the riddle would at once rank among great discoverers."

The authors italicize this remarkable statement: "*It is not improbable that Germany to-day is supplying a large part of her fats from synthetic production.*" If this be true, it becomes a matter of prime importance for our chemists to find a commercial process for the synthetic production of fats and fatty acids from hydrocarbons present in petroleum which the authors plainly indicate has already been, in a measure, successful, for they say in conclusion: "Fats and fatty acids from petroleum is more than an empty phrase."

I shall look for further information from them and I contribute this note with the view of calling the attention of your readers to the importance of their article.

ALEXANDER E. OUTERBRIDGE, JR.

Philadelphia, Pa.

Ammonia, Refrigeration and Munitions

To the Editor of Metallurgical & Chemical Engineering

SIR:—I was much interested in the article entitled "Ammonia, Refrigeration and Munitions," on page 277 of the March 15 issue of your journal.

Ever since this discussion of shortage of ammonia and the cutting down of its use by refrigeration plants came up, I have wondered that nothing appeared in the literature with reference to the substitution of liquid sulphur dioxide for the ammonia, and for some weeks I have been on the point of addressing you on this subject.

For quite a number of years sulphur dioxide has been used successfully in Europe for this purpose. It has many other advantages over ammonia, besides its much lower working pressure. I think it is from lack of correct knowledge, more than from any disadvantage inherent in this material, that it has not been used more for this purpose in this country.

I must take exception to the statement in your article that "SO_2 does not behave well in iron," unless that statement be qualified. It is true that liquid sulphur dioxide that is not pure and dry does attack iron, but it is also true that liquid sulphur dioxide which *is* pure and dry does *not* attack iron. At least one company in this country is making small refrigeration machines which are much more delicate than large commercial installations, using iron entirely for the cylinder and piston of the compressor, and, I believe, in all other places with which the gas comes in contact. When the gas used in these machines is sufficiently pure and dry they have no trouble with corrosion.

It is by no means as simple a process as most chemists would think, not having concrete experience with the matter, to separate water from, and dry perfectly, sulphur dioxide, but with properly designed apparatus, properly handled, this can be done with ease and certainty. The writer has made liquid sulphur dioxide on a large scale that has satisfied the most exacting requirements along this line.

It is perfectly true that but little of the liquid sulphur dioxide manufactured in this country, at least until recently, has been pure and dry; a number of the plants with which the writer is familiar for making this material have had installations for drying that were really laughable in their absurdity. One manufacturer passed his gas first up through a tower filled with packing, down which flowed sulphuric acid, *and then through a tower filled with calcium chloride to catch any sulphuric acid sprayed over from the sulphuric acid tower.* After this careful (?) drying it was stored in a gasometer *over water*, before being compressed and liquefied. This is hardly more absurd than other installations I have seen. Is it strange, then, that much of the sulphur dioxide on the market is not anhydrous?

Interest in the manufacture of liquid sulphur dioxide is increasing in this country, new plants are being erected and old ones remodeled. A tank car of special design has been proposed in which to ship the liquid, to do away largely with the excessive cost of transportation of the heavy containers usually used in shipping this and other compressed gases. Inasmuch as the pressure over liquid sulphur dioxide at ordinary tem-

peratures is so much less than that of most other liquefied gases, the use of such a tank car is possible. I think we can look for a large increase in the use of sulphur dioxide in the near future. While it is true that to the uninitiated there are many odd and unexpected troubles, yet to one with the necessary experience its manufacture is simple and without complication. It can be made readily from much of the sulphur gases now forming a nuisance in many communities. It could be used to great advantage in many places where sulphur is now burned to get the dioxide and no doubt in many places where sulphites are now used. With the increase in the amount manufactured, we can look for prices to drop to a point where its greatly extended use will be possible.

To the Editor of Metallurgical & Chemical Engineering

SIR:—In your issue of March 15 I note an article entitled "Ammonia, Refrigeration and Munitions."

In this article you state that sulphur dioxide cannot be used in ammonia compression systems. That "the pump and refrigeration pipes must be made of brass or copper for obvious reasons. SO_2 does not behave well in iron * * * ."

If you will investigate this subject further, I think you will find that you are in error in this statement. Sulphur dioxide in our experience, which has extended over a period of about seventeen years, performs just as well in iron and steel systems as in copper or brass; the latter, however, have an advantage in the matter of heat conductivity. If the sulphur dioxide is pure and reasonably free from moisture, and the proper lubricant supplied, there would be no difficulty in substituting it in ammonia systems. It is essential, however, that the ammonia systems be cleaned of ammonia and oil before introducing the sulphur dioxide.

The capacity for a given displacement, of course, would be considerably reduced, but in many cases refrigerating machines could be speeded up so that the plants could be operated at from 60 to 70 per cent of their normal rating.

In many cases machines are operated only a part of each 24 hours. By increasing the number of hours of daily operation, sulphur dioxide could be successfully substituted for ammonia, and still maintain full service in many existing refrigerating systems.

* * *

The Food Administration at Washington, in urging the conservation of ammonia, has very properly taken the position that the only way to save it is to save it. It would not have been good policy to suggest the substitution of SO_2 so long as there is any doubt on the subject. The opinion was also expressed that the substitution of SO_2 for NH_3 cannot be made successfully in the great quantity of refrigeration apparatus installed throughout the country, *as things are.* The same opinion was vigorously asserted by certain leading refrigeration engineers whom we consulted in regard to the matter. And it was a leading authority who insisted to us that in the long run sulphur dioxide refrigeration apparatus should not be constructed of iron. Our statement that "SO_2 does not behave well in iron" is open to the criticism that we should have said "moist SO_2." We took the moisture for granted because it is apt to be there.

But the problem involved is of far more importance than the correctness of our statements. There is prejudice as well as the fruits of research to be found in the art of refrigeration, and if prejudice stands in the way of progress we should try to remove it. The immediate problem is not to refrigerate with "properly designed apparatus, properly handled," but with the installations that are already built and duly set under all the eggs and fish. The drive is on, and all the ammonia there is—and then some more—is needed *now.* Let us admit that SO_2 may be suitably dried. Is it practicable to take a going concern now using ammonia, clean it speedily and effectively and shift over to sulphur dioxide without serious hazard of loss of stored merchandise or corrosion of the apparatus? Is it possible to test out such a change, using the same compressors, in a commercial plant of familiar design and thus prove that the substitution may be made generally? It would be a great boon, for it would release vast quantities of ammonia that are needed for munitions, provided it may be done now—right away. It would have to be done in existing apparatus without serious interruption of business.

If any of our correspondents has made the test and has the facts at hand, or is prepared to make the test to bring out the facts and prove that the change is practicable, our columns are open for him to tell the tale of it. We should be very glad to learn that in holding that the change cannot be made under existing circumstances, we were wrong rather than right. We are intensely interested in getting more ammonia for munitions and not at all vain about our own opinions.

EDITOR.

Sulphur Dioxide Method for Determining Copper Minerals in Partly Oxidized Ores

To the Editor of Metallurgical & Chemical Engineering

SIR:—Allow me to call your attention to an error in the article entitled "Sulphur Dioxide Method for Determining Copper Minerals in Partly Oxidized Ores," which appeared in your issue of February 15. Page 205, lines 26 to 29, inclusive, should read as follows:

"In general, when the solution to be standardized varies in strength from 1 to 3 per cent sulphur dioxide, add 1 cc. of this solution to 20 cc. of standard iodine solution. When the strength of the sulphur dioxide solution is appreciably below one per cent, add a larger quantity of this solution." The mixture is then treated * * *

This correction is essential to an understanding of the method presented.

Western Metallurgical and Chemical Field

Anaconda Company to Produce Ferromanganese

THE Anaconda Copper Mining Company will start immediately upon the construction of five electric furnaces of 4000 kw. capacity each for the production of ferromanganese, according to a statement by C. F. KELLEY, vice-president of the company. These furnaces will be installed in the present smelter building at Great Falls, which has ample room under the converter craneway. Consequently, with an excellent building and overhead cranes, a well-developed system for handling the materials and all the other auxiliaries at hand, the actual installation of the simple shaft furnaces will be a matter of a short time and dependent largely upon the procurement and delivery of the necessary transformers, electrodes and their automatic regulators. The necessary electric power, to the extent of about 20,000 kw., is already developed by the Montana Power Company, and can be delivered over present lines of large capacity connecting the Great Falls smelter to the hydroelectric plants farther down the Missouri River. Under such favorable conditions, it is hoped that the necessary special equipment may be procured by special arrangement, and the furnaces may be running by the middle of the summer.

The ores for their operation will come in large part from the Butte mines of the Anaconda Copper Mining Company, several of which have manganese-bearing oxides in their upper levels. In fact, a quantity of manganese ore has been collected from various shallow prospects and old dumps by ore-pickers and marketed through a local mill. In addition to these supplies, which will be fully exploited, the neighboring Phillipsburg district has been developed into one of the most important manganese producers in the United States, now shipping about 500 tons of 45 per cent ore daily, any necessary part of which may be diverted to the new furnaces. The plant is expected to produce 100 tons of ferromanganese per day.

Potassium Sulphate from Cement Dust

A rather unique and successful plant for the recovery of potassium from cement-kiln dust has been installed at the Southwestern Portland Cement Company by MR. J. G. DEAN, their chemical engineer. The cement plant is operating under the wet process, and the stack gases average about 40 per cent water vapor at a temperature of 600 deg. Fahr. They are first conducted through a dust chamber 200 ft. long placed underneath the kiln, where six or seven tons per day of the heavier dust particles are deposited. The gas then passes through a concrete flue to a fan, which delivers it to a spray chamber where a water spray brings down most of the remaining dust. The gases, heavily laden with the water vapor, are then sent to a condenser, and on being cooled the moisture begins to condense on any dust particles which may remain, and, of course, if these particles happen to contain potash, it is dissolved and washed out with the condensate.

This condensate is pumped into suitable tanks and is used as the condensing medium on the other side of the condenser tubes. The difference in temperature necessary is maintained by a vacuum of 24 in. (with a barometer of 27 in.), so that the installation, which, by the way, is entirely of reinforced concrete, is in effect a combined condenser and evaporator. This brine or condensate is eventually evaporated to saturation, when the potash salts crystallize out as sulphates.

It will be seen that this installation has considerably more evaporating than condensing capacity. In other words, they are condensing about 150 lb. of water per minute, and evaporating about 300 lb. per minute, which permits them to do any necessary extra scrubbing.

The chemistry of the process is very interesting. It has been found that by regulating the burning so as to maintain a slightly reducing condition in the kiln, the condensate holds in solution the following ions: K, Na, SO_4, CO_3 and S_2O_3. Some of the carbonates are changed to bicarbonates, and these serve to eliminate the sulphides. Since there is not quite enough of the sulphate ion to unite with all of the potassium ion, this deficiency is supplied by running the solutions through a bed of gypsum. This removes the carbonate ion and supplies the necessary sulphate and makes it possible to crystallize a very pure potassium sulphate, and at the same time produce a sodium thiosulphate of value.

There is no particular labor expense attached to the installation at the Southwestern Portland Cement Company other than the wages of one or two attendants necessary to take care of the collecting and refining apparatus. In other words, the flue dust collected will pay all the expense of collection and purifying, so that the potash is really so much profit.

Potassium Sulphate from Alunite at Marysvale, Utah

The rebuilt plant of the Mineral Products Corporation at Alunite, near Marysville, Utah, has started operations and is producing twenty tons of 97 to 98 per cent potassium sulphate per day. The original plant was constructed by Westinghouse, Church, Kerr of New York, and was admittedly of experimental nature. It was highly successful, however, and immediately after the fire of Oct. 25, 1917, a contract for reconstruction was placed with the Industrial Engineering Company of Salt Lake City. Current reports that the fire which destroyed the leaching, evaporating, storage and power buildings was of incendiary origin are incorrect, as the source was undoubtedly a spontaneous fire in the coal-pulverizing plant.

The general plan of the new works follows that of the old, with minor modifications found desirable by the early operations. Fortunately the evaporators themselves were damaged but slightly, and the crushing department and kiln rooms uninjured. Briefly, the process in use is as follows: The alunite, a moderately hard, brittle mineral (a hydrated double sulphate of potassium and aluminium) is first crushed to about 1-in. size and then roasted in a rotary kiln much like the familiar cement kiln, a brick-lined cylinder 7 ft. 6 in. in diameter and 135 ft. long, fired with pulverized coal. The calcined material is then leached with hot water in a closed tank at a temperature corresponding to 60 lb. steam pressure, which takes the K_2SO_4 into solution. The larger pieces of insoluble siliceous material are unaffected by this digestion, and are removed

from the liquor by merely screening. The solution is then filtered in a Kelly filter-press, which removes the fine solids—largely Al_2O_3 minus 300-mesh, together with a small percentage of silica and iron oxide. The clear filtrate is then evaporated in Swenson triple-effect evaporators, when the resulting crystals are centrifuged and sacked for shipment.

The company is planning to take up the matter of disposal of by-products as soon as the new plant attains its rated capacity of 30 tons of potassium sulphate per day. The alunite mined by the Mineral Products Corporation is contaminated with a relatively small amount of impurities. The coarse screenings, silica and aluminium silicates should therefore make excellent refractories, while the filter-cake, if it can be purified of the small amount of iron and silica it contains, should be converted into aluminium metal or aluminous abrasives.

Placer Platinum in California and Oregon

Chemists and metallurgists have long been interested in the high price of platinum which has all but prohibited purchases of new scientific equipment made of this element. Its absolute necessity as a munition is further emphasized by a war department order issued early in March requisitioning all crude and unworked platinum in the hands of importers, jobbers and wholesalers.

The platinum metals are found in quantities of economic importance at only a few places. The bulk of the world's production has heretofore been furnished by the placers of the Ural mountains, in Russia, but the production from this source is decreasing, while Colombia is becoming an increasingly large producer. Under normal conditions the United States requires about 165,000 oz. a year, while we produce only a few thousand ounces, and have met with increasing difficulties in importing sufficient supplies. The only considerable recent importation was a lot of about 21,000 oz. collected in Russia by Norman C. Stines, managing director of the Sissert Mining District Company, and brought to America in the baggage of a returning engineer, S. W. Draper.

The small American production, aside from that recovered from the refining of blister copper, is almost entirely recovered incidental to gold placer mining operations in California. At periods of about fourteen days the gravel contained in the sluices is cleaned up and the waste washed out with a hose stream, leaving behind a small pile of sand and amalgam. This material is again washed over a smaller riffled sluice containing traps for the "quick," and the resulting black sand containing the platinum, with some gold, osmium and iridium, is shipped to a refinery. Jas. W. Neill* estimated that a 3¾-ft. dredge mining about 68,000 cu. yd. per month was losing apparently 4.75 oz. of recoverable platinum per month, against a total caught and saved in the riffles of about 1.85 oz., and he installed a small Wilfley table to retreat the 20-mesh hutch product of jigs set below the sluices to catch tramp amalgam. It would be too much to expect the sixty-five million yards of gravel dug annually by the dredges in California to produce platinum at this average rate (1 oz. per 10,000 cu. yd.) since the output, 6500 oz. of platinum, would then far exceed the total of 710 oz. produced during 1916. Doubtless much more could be recovered by intelligent effort before the additional cost would overbalance the returns.

*Mining and Scientific Press, Dec. 8, 1917, page 828.

Smoke Purification at Anaconda

Shortly after operations at the Washoe Plant were started by the Anaconda Copper Mining Company some fifteen years ago, it was seen that the plan of having individual smokestacks for each department was causing considerable smoke damage to the surrounding country, and heavy expenditures were immediately undertaken to provide long flues connecting the various furnace buildings to a much wider hopper-bottomed flue acting as a dust chamber and leading up the hill to the "big stack" 30 ft. in diameter and 300 ft. high. In this way this pioneering organization showed their faith in that palliative which the most recent and painstaking research has shown to be the only known commercial method of disposal of dilute sulphur dioxide; that is to say, adequate dissemination in the upper atmospheric strata.

The continual increase of the amount of ore treated in this huge smelter has gradually overloaded even this flue system. Klepinger's studies, and the resulting flue system and stack at Great Falls, amply demonstrated the financial advantage of making adequate clearance of the solids, while additional pressure was brought to bear on the company by the final decree of their numerous and hard-fought "smoke suits." In the meantime, Dr. Cottrell's system for smoke clearance had been closely investigated, both in large and small-scale tests, and it was finally determined to build such a treater capable of handling the entire gases of the smelter (some 2,000,000 cu. ft. per minute). This program calls for an initial expenditure of about $2,500,000 and is well under way at the present time; wagon and railroads up the hill to the site are completed, and the excavation and foundation work is finished.

The new treater and stack will be located on a high ridge leading to the south of the present 300-ft. stack. The gases will be drawn from the top and end of the old flue where it branches out to either side before entering the old stack, through a double flue alongside a treater plant located beyond both chimneys, and thence back into the new chimney through flues placed between the treater structures. The chimney will be constructed of locally made brick, and will be 60 ft. inside diameter at the top and 525 ft. high, and is thought to be the most massive in existence, comparing in bulk with the Washington monument.

The treater plant itself will originally contain twenty sections, in two parallel lines of ten each, and will use "box-type" passageways, consisting of corrugated iron partitions for dust collecting, 12 in. apart, with a series of electrified chains suspended between 5-in. centers. The voltage used will be 75,000. Sufficient ground area has been prepared for doubling the treater construction, should it prove desirable in the future.

The recovered dust will be smelted nearby in a large modern reverberatory furnace, producing a matte containing the metallic values. The gas from this furnace will pass through a hot treater, recovering the true dust it contains for return to the furnace, and a cold treater, will precipitate the condensed metalloids, largely As_2O_3.

Important Developments Relating to Labor and Capital

National War Labor Board Recommended by Representatives of Employers and Emlpoyees. Standard Oil Co. of New Jersey Introduces Industrial Democracy. Mining Engineers Discuss Labor Problems

THE War Labor Conference Board composed of five representatives each of employers and employees, and two representatives of the public, appointed some time ago at the suggestion of Secretary of Labor Wilson to aid in the formation of a national labor program for the period of the war, has made its report and recommendations as follows:

That there be created for the period of the war a National War Labor Board with the following functions and powers:

1. To bring about a settlement by mediation and conciliation of every controversy arising between employers and workers in the field of production necessary for the effective conduct of the war.
2. To do the same thing in similar controversies in other fields of national activity, delays and obstructions which may, in the opinion of the National Board, affect detrimentally such production.
3. To provide such machinery by direct appointment, or otherwise, for selection of committees or boards to sit in various parts of the country where controversies arise, to secure settlement by local mediation and conciliation.
4. To summon the parties to the controversy for hearing and action by the National Board in case of failure to secure settlement by local mediation and conciliation.

In case the National Board is unable to effect a voluntary settlement or agree upon a decision, an umpire shall be chosen by unanimous vote or drawn by lot from a list of ten persons nominated by the President of the United States. No cognizance will be taken of a controversy between employer and workers in any field of industrial or other activity where there is by agreement or federal law a means of settlement which has not been invoked.

In their capacities as mediator or conciliator the Board or the umpire shall be governed by the following principles:

No Strikes or Lockouts During the War

The right of workers to organize in trade unions and to bargain collectively, and the equal right of employers to organize in associations and to bargain collectively, is recognized and affirmed, and shall not be denied, abridged or interfered with by either party. Employees should not be discharged for membership in trade unions, nor should they use coercive measures to induce persons to join their organizations, nor to induce employers to bargain or deal with them.

Present conditions as to union, non-union or open shops are to continue. Established safe-guards and regulations for health and safety shall not be relaxed. Women employed on work ordinarily done by men must be allowed equal pay for equal work. The basic eight-hour day is recognized as applying in all cases in which existing law requires it. In all other cases the hours of labor shall be settled with due regard to governmental necessities and the welfare of the workers.

Maximum Production to be Maintained

The maximum production of all war industries should be maintained, and methods of work and operation on the part of employers or workers which operate to delay or limit production, or which have a tendency to artificially increase the cost thereof, should be discouraged.

For the purpose of mobilizing the labor supply with a view to its rapid and effective distribution, a permanent list of the number of skilled and other workers available in different parts of the nation shall be kept on file by the Department of Labor, the information to be constantly furnished by the trade unions; by state employment bureaus and federal agencies of like character; by the managers and operators of industrial establishments throughout the country.

The recommendations recognize the right of all workers, including common laborers, to a living wage. In fixing wages, hours and conditions of labor, regard should always be had to the labor standards, wage scales and other conditions prevailing in the localities affected. Minimum rates of pay shall be established which will insure the subsistence of the worker and his family in health and reasonable comfort.

Standard Oil Co. Launches Industrial Plan

On April 1 a group of the officials of the Standard Oil Co. of New Jersey and some seventy delegates elected by the workmen in the New Jersey plants met at dinner at the company's offices in New York. The announced purpose was to bring employer and employee together for the free discussion of matters of mutual interest. It was definitely stated that there was not the slightest strain in the present or prospective relations between company and workmen, and that the idea of meeting together was to effect still closer relationship and insure continued harmony between the company and its employees.

The dinner marked the beginning of industrial representation among employees in the Standard Oil Co. A consequence of far reaching importance is the practical assurance of harmony in the organization during the war. Considering the importance of petroleum and its products it is highly desirable that there should be no disturbances in oil-producing concerns.

President Teagle announced an increase in wages effective April 1, averaging 10 per cent., applicable to all wage earners except first-class bricklayers and watchmen whose rates are increased 5 per cent, and lead burners whose rates were previously increased.

C. J. Hicks, executive assistant to the chairman of the board, explained certain plans which the company has for its employees, including a system of benefits and annuities. Arrangements are to be made whereby all

employees, after one year's service, without cost to themselves, shall be given an individual life insurance policy. One year's service carries a death benefit equal to three months' full pay; two years' service, five months' full pay, and so on progressively, until five years and over carries the equivalent of twelve months' full pay, with a minimum of $500, and a maximum of $2000.

Annuities are planned on the basis of a regular allowance of 2 per cent. of salary for each year of service for all employees at the age of 65 years, after twenty years' service, with a minimum of $300 per annum and a maximum of 75 per cent. of salary. Special provisions are made for employees less than 65 years of age, retired after twenty and twenty-five years of service.

Regulations were proposed governing the discharge of employees, and a list of offenses was agreed upon for which alone a man shall be subjected to summary dismissal. For other offenses the employee is to have due warning before dismissal. In case of possible injustice, the privilege of higher appeal is reserved to the worker.

Plans are under way for improvements in sanitation and housing at the company's plants. These were explained in detail by Mr. Hicks, who announced that Mr. Rockefeller had subscribed $50,000 to the Bayonne Housing Corporation and had donated that stock to the new Bayonne Y. M. C. A. toward the construction of which he had also given $100,000.

Mining Engineers Discuss Labor Problem

At the April meeting of the New York Section of the American Institute of Mining Engineers the evening was devoted wholly to a discussion of the labor problem. Following is a report of the proceedings.

Mr. Sidney J. Jennings, vice-president of the United States Smelting, Refining & Mining Company, traced the origin of the company from its inception to the present time. He found that the fundamental idea of the company and of the issuance of shares was one of co-operation. He then analyzed the present relation of the company to industry and said that if the company was not fulfilling its proper function it might have to be abolished. He found three dangers besetting the proper conduct of the modern company. First, the capitalist becomes divorced from a sense of personal responsibility in the operation of the business; second, the actual manager or management may have considerable power without having any capital interest in the concern; and third, the laborer or worker feels that he is only a cog in the big wheel.

Mr. Jennings suggested the following methods for overcoming the feeling which the laborer has that he is only a cog in the machine. He cited the fact that the United States Steel Corporation offers actual partnership through the purchase of shares in the corporation. Second, he thought that profit-sharing above a fair return was one of the best means of making the company a true co-operative agent. Third, he felt that a central employment manager was almost essential to maintaining harmonious relations between the company and the workers. A good employment manager can be responsible for either the good-will or the ill-will of employees which in turn means success or failure of the institution.

Mr. Walter Douglas of the Phelps, Dodge Corporation operating copper mines in Arizona, said that it was becoming increasingly difficult to get the viewpoint of the wage earners due to the increasing numbers of men employed by individual companies. He contrasted former conditions when the employer, manager or shift-boss had so few working under him that he knew them all personally and could get their viewpoints very readily, with present conditions where concerns have thousands and tens of thousands of men in their employ without the possibility of knowing them all personally or getting their point of view. He thought that some substitute must be found to bring about the close personal touch which formerly existed in the small companies. He spoke of the necessity of getting specialists to analyze labor problems for companies and thought that engineers should be the first to seek the aid of such specialists. He thought that the manager of a concern is not suited to this particular kind of work and yet he is the one who most frequently tries to solve the problem himself. Mr. Douglas believed that the solution will be found in some intermediary between the employer and the employee, and stated that the labor union has not yet filled this gap. He was quite certain that the big problem in the labor situation is not one of wages or hospital dues or any such item, but rather the thousands of little things that the company knows nothing about until a crisis comes. It would be the duty of an intermediary to know what these things are and to correct evils before they develop into crises. The type of man best able to deal with labor would be one who has been a leader of labor himself, and he cited Secretary Wilson and Mr. Mitchell as types who would be good intermediaries for large concerns. Speaking for the Phelps, Dodge Corporation he said that they had an employment agent at the Copper Queen mine whose duty it was to employ, transfer and dismiss all workers. The foreman of any department could not dismiss a man but was obliged to inform the employment manager that the man was not suitable for that particular work, whereupon the employment manager would transfer him to some more suitable place. The company has a pension system for those who have worked for the company for fifteen years. The pension is 2 per cent. of the salary for the number of years worked, and has a maximum of $1000 per annum. The company operates a benefit association to which 80 per cent of the employees belong. The company contributes about an equal amount with the employees. This past year an experiment was made in offering a flat service bonus of $100 to every man who had worked for the company one year. This was offered without regard to his position or salary and was a straight premium for sticking to the job.

Targets of Labor Agitators

Mr. Douglas said that the points on which the labor agitators had played most strongly were the company store and the hospital. He showed that the company store reduces the cost of living and that only recently 90 per cent. of the employees at Ray, Miami and Globe had petitioned his organization to establish company stores at those places. He felt that the hospital is a different problem and that if the company does not run it, it will not be run right and the men will not receive adequate attention. The charge for this service is nom-

inal and yet the agitators always find a good deal of fault with both the company store and the hospital in spite of the fact that both institutions are for the good of the employees. Mr. Douglas then touched briefly on the work of the president's mediation committee which settled the recent fight in Arizona. This report has been published by the U. S. Department of Labor.

Mr. J. Parke Channing said that while the United States had been efficient as far as methods and processes are concerned, we have not been efficient in the utilization of our man power. He cited the change which has taken place in England since the beginning of the war and showed that England had become a socialistic community which was highly efficient, with the government doing almost everything. He said that the English laborers were not going to be content to return to the old order of things. He admitted that the problem in Great Britain was simpler than in the United States on account of the fact that practically all of England's laborers are English, while the United States has a mixture of unassimilated foreigners. He felt that if we are to carry the war to a successful conclusion and increase our efficiency after the war we must Americanize our foreigners and give them our own point of view. He then outlined the proposed program of the British labor party which has four principles or pillars, namely,

1. Universal enforcement of the national minimum.
2. The democratic control of industry.
3. The revolution in national finance.
4. The use of surplus wealth for the common good.

If these four demands are carried out, England will be a socialistic state. Mr. Channing did not presume to say how much this program could or should be carried out but cited it as showing the trend of thought in England.

The British workman has seen his wages increase and he is more than ever convinced that in the past he had not been getting his fair share of the products of his toil. Mr. Channing also believed that the workman was realizing that he had not done his proper share toward increasing the wealth of the country. Generally speaking the British workman has seen such good results obtained in the democratic control of industry during the war that he feels that such control should be just as efficient after the war. Mr. Channing distinguished between the English labor party and the Bolsheviki of Russia, saying that the former did not believe that the working class should manage the country; that the English labor realized the importance of brains and education and the necessity of these things in bringing the country to the highest state of development. He felt that a program similar to that in England was likely to come up in the United States and that we should be on our guard lest the pendulum swing too far, as it is likely to do if the employing class does not give more attention to the worker and see that his condition is improved. He felt that engineers were the best instruments for carrying out the necessary work. He spoke of the growing tendency to give engineering students some training in human engineering and cited such courses at Columbia University. In discussing trade unionism he said that Professor Hoxie's work on Trade Unionism in the United States would clarify anyone's ideas of that subject and suggested that the book be read by all engineers. He spoke very favorably of the work of the industrial department of the Y. M. C. A. in human engineering.

Success of Conciliation Board in Anthracite Field

Mr. Edwin Ludlow, vice-president of the Lehigh Coal & Navigation Company, agreed with Mr. Schwab that "labor is now in the saddle." He said that the time had come when we must have captains of labor as well as captains of industry and that both of these factors must get together if we are to have the best development of industry. He reviewed conditions in the anthracite fields of Pennsylvania beginning with the strikes some years ago which were settled by Mr. Roosevelt. He explained the nature of the commission which was established at the time and reviewed the document which that commission drew up and which has stood the strain of fifteen years of active application. The most important feature of the method of settling disputes was the establishment of a board of conciliation which was the final arbiter. Another important point was, that pending the adjudication of any disagreement there should be no suspension of work either by lockout or strike. Mr. Ludlow thought that we made a mistake if we do not encourage the better class of men to join the union so that those organizations will be directed by the best thought among the laborers.

Dr. E. E. Southard, a physician and one of the directors of the Psychopathic Hospital of Boston, spoke of the possible use of the psychologist in handling labor for large organizations. He felt that there was a reasonably good field already developed for this type of scientist in assisting large concerns to get the right men for the right jobs and to analyze a good many conditions which are purely psychological in their character.

Mr. R. J. Young of the Illinois Steel Company told what that organization had done in a very elaborate way toward taking care of its employees and trying to establish harmonious relations between the workers and the company. He laid considerable stress on the idea of an employment manager whose function it was to secure a desirable labor supply. He spoke of part ownership by employees and suggested that when a certain percentage of the total stock was owned by employees they should have representation on the Board of Directors of the company. With regard to pensions he raised the question as to whether the amount paid should be based on the wages of the man or on his ethical value to the company. He thought that basing a pension solely on the wages previously earned was not wholly a fair method. Mr. Young then outlined very briefly the numerous activities engaged in by the steel corporation in an effort to create good working conditions and establish harmonious relations between the company and the men. Among these efforts were medical supervision, dental clinics, shop sanitation, industrial canteen, domestic science instruction for the laborers' wives, proper illumination of shops and homes, fire prevention, proper ventilation, recreation for the workmen and their families, education for the children, housing and insurance. He laid considerable stress on the value of picking proper individuals for foremen because they represent the management to the men and hold very important positions in the organization.

The Solubility of Paraffins, Aromatics, Naphthenes and Olefins in Liquid Sulphur Dioxide

A Study of the Possible Utility of Liquid Sulphur Dioxide in Oil Refining and Analysis. Solubility of Pure Substances and Separation of Mixtures

BY ROBERT J. MOORE, J. C. MORRELL AND GUSTAV EGLOFF

IN THE analysis and refining of oils, the question of procedure has long been a vexed one. Methods for the determination and isolation of the various constituents of natural petroleums and artificial oil mixtures follow no general scheme and are of questionable accuracy. The well known sulphonation for olefins and nitration for aromatics have long been used as more or less approximate tests for the want of something better. Moreover with this method the unsaturated and aromatic hydrocarbons are lost, since their recovery from the acid sludge is difficult, and their physical properties therefore are based on calculation of the oil before and after treatment, giving questionable results. The present paper is a contribution to the analytical and refining methods on hydrocarbon oils based on their solubilities in liquid sulphur dioxide.

In 1892 Walden[1] used liquid sulphur dioxide as a solvent for many inorganic and organic substances, dissolving, among others, benzene, phenol, naphthalene, aniline and diphenylamine. This property of liquid sulphur dioxide to dissolve certain organic substances was used by Edeleanu[2] in the refining of crude petroleums. He found that "if a distillate is agitated with liquid sulphur dioxide at a low temperature the aromatic compounds are dissolved but the paraffins and naphthalenes are unaffected." With this as a basis he evolved the process bearing his name, which has been used to some extent in Italy and Germany. In his paper Endeleanu shows the efficacy of his process in refining many illuminating oils and compares results with the ordinary methods of refining. He finds also that liquid SO_2 has a marked effect in removing certain sulphur-bearing compounds along with the aromatics.

The admirable work of S. E. Browery[3] which has recently come to the authors' attention takes up the refining with liquid sulphur dioxide in more detail. Using Edeleanu's method at —12° C. Browery found that conditions applied to purifying lamp oil do not hold for lighter fractions. For example, at —12° C., the lamp-oil fraction from a Trinidad crude, treated three times with half its volume of sulphur dioxide gave highly satisfactory separation. On the other hand a light distillate (up to 150°C.) from the same crude yielded extracts containing about equal parts of aromatics and paraffins. By working at lower temperatures than —17° C. it was found possible to improve results up to a point at which satisfactory correction could be applied by means of specific gravity determinations. A series of extractions run on artificial mixtures containing about 15% aromatics and using temperatures to —35°C. (Obtained by evaporating liquid SO_2) showed fairly accurate results. The method was applied to the determination and recovery of toluene in crude oil from Trinidad Central. Browery states that "naphthenes are insoluble in SO_2 and are therefore left with the paraffins."

Rittman and Moore[4] in 1915 published a note on the liquid SO_2 method of separating aromatics from paraffins. Their results show fairly good separations for low percentages of aromatics but not on higher percentages. In their work which was merely a preliminary note on method, the burette was embedded in ice and salt mixture and its removal for volume reading took time and made temperature readings uncertain.

Scope of Present Work

The literature contained no work on the individual solubility in liquid sulphur dioxide of the various hydrocarbons. As this seemed essential to any comprehensive work the curves of various pure compounds were determined. The results on naphthenes were contrary to the statements of both Edeleanu and Browery and are discussed later. The solubility of the following dydrocarbons was determined: Pentane plus hexane, hexane, octane, nonane plus decane; washed gasolene, washed kerosene; benzene, toluene, xylenes, mesitylene; hexalene, caprylene; cyclohexane and naphthenes boiling within the following limits, 75°-155°, 155°-175°, 175°-185°. These solubilities were determined at temperatures of —10° C. and —18° C. A series of SO_2 treatments was then run on a number of synthetic mixtures and results tabulated.

Procedure

A modification of Edeleanu's apparatus was used as illustrated in Fig. 1. The oil to be treated was run into the graduated burette, then placed in the cooled alcohol bath and its volume read, the temperature of the bath being recorded on a toluene thermometer. A zinc tube embedded in a freezing mixture of ice, salt and calcium chloride served as the container for the alcohol bath, the outer container being well insulated with heavy felt. It was found that this apparatus could be kept at almost constant temperature over a range of 75 minutes for the lower temperature. The liquid SO_2 was run in from a tank through heavy-walled rubber pressure-tubing. The volume of SO_2 was read off as the increase in volume in the burette. A modification of this was used on mixtures. The SO_2 was first run out into a glass stop-cocked closed burette. This burette was then attached by means of heavy rubber tubing to the burette containing the oil and the volume of SO_2 used read off on the first burette. If separation into two layers occurred, both volumes were read. Burettes of various capacities were used depending on the volume of oil to be treated or the volume of SO_2

to be added. The separated layers were run off into different tubes and the SO_2 separated either by evaporation or by solution in dilute sodium hydroxide, after which the separated oils could be measured and their specific gravity and indices of refraction determined. The latter were measured with a Pulfrich refractometer. Specific gravities were taken with a Westphal balance where possible or with a 1-cc. pycnometer.

In several instances, where minute quantities of one or two drops were separated, a special method had to be devised for the accurate determination of such small quantities. The method finally adopted may prove useful to experimenters in determining this physical constant of minute quantities, one drop of the substance being sufficient for a number of measurements. The method employed was as follows: A two or three-inch piece of fine, thin-walled, capillary tubing is weighed on an accurate balance to the fourth decimal place. Then, held upright in a small pair of weighing forceps, the lower end is dipped in the drop of substance which immediately fills the entire tube due to capillarity. As soon as it is filled it is placed on the pan of the balance and weighed again, the increase giving the weight of the substance. The tube is then cleaned and its volume determined by weighing filled with water. The specific gravity is then calculated for the temperature at which the tube was filled. If the substance under examination is highly volatile, the capillary tube as soon as filled may be placed in a small glass-stoppered weighing bottle. This method was checked up by the Westphal balance on toluene, benzene, and alcohol and gave satisfactory results on volumes as low as 0.012 cc.

Hydrocarbons Used

The physical properties of the oils used are given in groups in Table I.

TABLE I. PARAFFINS

Name	B. P. °C.	Sp. Gr. (Westphal) 15.5° C.	(Pulfrich) Index	Treatment with Conc. H_2SO_4 and Conc. HNO_3
Petroleum Ether (Butane, Pentane and Hexane)	Below 50°	0 643	1.3629	No coloration

Naphthenes

Name M. P.	B.P.	Sp. Gr.	Index	Remarks
Cyclohexane, 6.4°	80–80 2	0 780	1.4255	No coloration with H_2SO_4 or HNO_3
Naphthenes	75–155	0 784	1.4267	
Naphthenes	155–175	0 799	1.4345	No coloration with H_2SO_4 or HNO_3
Naphthenes	175–185	0.809	1 4379	No coloration with H_2SO_4 or HNO_3

* The gasolene and kerosene were distilled from Pennsylvania crude, washed repeatedly with fuming sulphuric acid, neutralized with dilute sodium hydroxide, washed with water and dried over calcium chloride

The cyclohexane was a particularly pure specimen melting at 6.4°C. The sulphuric acid and nitration tests showed no trace of either olefins or aromatics, and the absence of paraffins was sufficiently proven by its specific gravity, index of refraction and sharp freezing point.

The higher boiling-point naphthenes used were distilled from naphthene-base oil distillates used in a previous research.[5] The following fractions were used: Boiling points 75°-155°, 155°-175° and 175°-185°. These were washed free from olefins and aromatics. The specific gravity and index of refraction of these fractions indicate their naphthenic nature. In Table II these values are compared with the physical properties of pure paraffins and pure naphthenes.

TABLE II.

Boiling Point Range °C.	Pure Paraffins *	Pure Naphthenes *	Oil Used
75–155	Sp. Gr. —0 712	0 778	0.784

	Index —1 4158	1 433	1.4379

* Values taken from Engler—Hofer, Das Erdol.

The paraffin and naphthene hydrocarbons are almost identical in their inactivity toward reagents, and therefore offer difficulty in distinguishing one from the other. But if we know that an oil is free from olefins

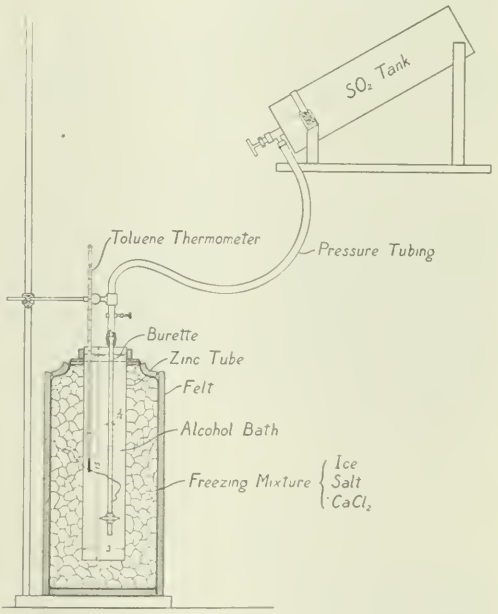

FIG. 1.

and aromatics, through sulphonation and nitration, specific gravities and refractive indices are sufficiently wide apart to distinguish pure naphthenes from pure paraffins. The above table shows that in each case the properties of the oil used closely approximated the values for the pure naphthenes, and were sufficiently higher than the value for paraffins to assure absence of the latter. The difference in their behavior with the liquid sulphur dioxide checked up their difference in chemical structure.

[5] Egloff and Moore, Met. & Chem. Eng., XV, 6, 1916.

Solubility of Aromatics in Liquid SO_2

The solubility of pure aromatic hydrocarbons in the liquid SO_2 is shown in Graph I. Two different percentages of liquid SO_2 were used, 33.3% and 66.7% and two temperatures —18°C. and —10°C. The four aromatics used, benzene, toluene, xylene and mesitylene were completely miscible in all cases. In using the benzene which freezes at 6°, the SO_2 was run into the kerosene at room temperature, shaken and then placed in the bath. With 33.3% SO_2 only a slight turbidity was visible due to a tendency of the benzene to freeze.

Solubility of Paraffins in Liquid SO_2

The insolubility of paraffin hydrocarbons is shown in Graph I. Pentane plus hexane, hexane, octane, nonane plus decane, gasolene and kerosene are shown to be insoluble at —18° and —10° and with varying proportions SO_2. With kerosene at —18°, from 33.3% to 98% SO_2 were used. The relative solubility of the liquid SO_2 in paraffins was determined ranging from an unmeasureable quantity at —18° to 1.8% at —10° for the low boiling-point members and increasing in solubility to 3.6% in the higher boiling kerosene oil. There was in no case an indication of paraffins appreciably dissolving in the liquid sulphur dioxide.

Solubility of Olefins in Liquid SO_2

The solubility of olefins in liquid SO_2 is shown in Graph I. The behavior at —18 deg. and —10 deg. for 33.3 per cent and 66.7 per cent liquid SO_2 corresponds to that of the aromatics, namely, entire miscibility.

Solubility of Naphthenes in Liquid SO_2

The solubility of naphthene hydrocarbons is shown in Graphs I and II. Edeleanu (loc.cit.) and Browery (loc.cit.) both state that naphthenes are entirely insoluble in liquid sulphur dioxide and after treatment are left with the paraffins. The present work, however, indicates that naphthenes vary in solubility from 0 to 100 per cent depending on the temperature and concentration of the liquid SO_2. Graph II shows the solubility of pure cyclohexane at temperatures of —18 deg., —10 deg., —7.5 deg. and —4.5 deg. C. and at percentages SO_2 ranging from 45 to 91. Below 45 per cent SO_2, that is, nearly an equal volume, there is no solubility at —18 deg. C. and only 3 per cent at —4.5 deg. C. With about 70 per cent SO_2, however, the solubility shows a marked increase. The solubility also increases rapidly with temperature; with 89.4 per cent SO_2 the solubility is about 58 per cent at —18 deg. and 100 per cent at —4.5 deg. C. One marked peculiarity of the naphthene action with SO_2 is that as the concentration of SO_2 reached a point between 83 per cent and 87 per cent white crystals appeared in the oils, remaining upon addition of more SO_2.

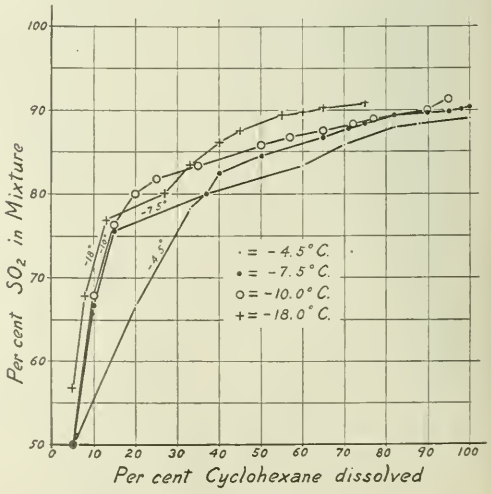
GRAPH 1.



GRAPH 2.

the naphthenes. The literature contains examples of compounds forming between liquid SO_2 and organic substances. For instance, De Bruin,[6] mixed isoprene with an equal volume liquid SO_2 and obtained a crystalline compound of the composition $C_5H_8.SO_2$ of definite melting point, 62.5 deg. Baumé and Pamfel[7] working with liquid SO_2 and methyl alcohol found indications of the formation of $CH_3OH.SO_2$ and $2CH_3OH.SO_2$. The case in question does not seem to be plain solubility but probably formation of a compound which is stable only at low temperatures and in the presence of considerable SO_2. Further investigation on this point is being conducted.

The naphthenes of higher boiling-point (Tables III and IV) show a much smaller solubility than cyclohexane. The fraction 175 deg. — 185 deg. is insoluble up to 80 per cent. SO_2 but shows a marked increase from there on, giving a solubility of 23 per cent upon the addition of only 8.5 per cent more SO_2.

One of the difficult problems heretofore in oil work has been the determination of naphthenes in the presence of paraffins. The usual method has been merely a calculation based on the boiling point, index and specific gravity of the unvitratable oil;[8] while Kramer and Bottcher's method involves fractionation to within one or two degrees and carbon and hydrogen determinations of these fractions to estimate naphthenes present. These methods obviously are proximate at best, the second one involving considerable manipulation. The action of liquid sulphur dioxide therefore may prove a valuable aid not only in estimating napthenes in paraffins but separating them for further test. The application of this method to the separation of synthetic mixtures of naphthenes and paraffins is given later.

ACTION OF SULPHUR DIOXIDE ON SYNTHETIC MIXTURES

The work on synthetic mixtures is divided into six sections, as follows:

A.—Paraffin-Aromatic Mixtures.
B.—Naphthene-Aromatic Mixtures.
C.—Paraffin-Olefin Mixtures.
D.—Paraffin-Naphthene Mixtures.
E.—(a) Olefin-Naphthene Mixtures.
(b) Olefin-Aromatic Mixtures.
F.—Paraffin-Aromatic-Olefin Mixtures.:

A.—Paraffin-Aromatic Mixtures

Benzene-Hexane, Table V.
Toluene-Octane, Table VI.
Toluene-Kerosene, Table VII.

Although the aromatic oils are entirely miscible with the solvent used, while paraffin oils are insoluble, the paraffin-aromatic mixture treated with the solvent presents many complexities. In the first place, the system aromatics-sulphur dioxide has a capacity for dissolving paraffins which sulphur dioxide alone has not. This is shown in the above tables by the increasing solubility of the paraffins as the percentage of aromatics in the mixture is increased. With 50 per cent benzene present, the paraffin-aromatic mixture is 100 per cent soluble. This is true also for the toluene-paraffin mixtures. The extraction of aromatics by sulphur dioxide is, therefore, limited to mixtures containing below 50 per cent aromatics, and efficient extraction is possible only below 25 per cent aromatics. Table V shows that from a mixture containing only five per cent benzene, it is possible with one extraction to separate an oil of 88.3 per cent benzene content, using an equal volume of sulphur dioxide. The percentage of benzene content is calculated, in each case, from the index of refraction, using the formula

$$\frac{(m - p)100}{a - p} = \text{aromatics}$$

where m = index of mixture;
p = index of paraffins used;
a = index of aromatics used.

As the percentage of benzene in the original mixture is increased, the solubility of the mixture rapidly increases, the bulk of the aromatics being extracted. With 15 per cent benzene in the mixture it is possible to separate nearly all the aromatics, the extraction representing 76.5 per cent benzene. Both the toluene and benzene mixtures show best extractions when the aromatics are present to an extent not exceeding 20 to 25 per cent. Certain natural petroleums which contain aromatics usually are under 15 per cent in aromatics content, and therefore lend themselves admirably to the sulphur dioxide extraction. This ideal percentage of about 15 per cent aromatics was used by Browery (loc.cit.) in extractions with sulphur dioxide and yielded

[8] Engler-Hofer, Das Erdöl, on Naphthenes.

satisfactory results, especially when a number of extractions were made, using each time small quantities of the solvent.

In Table VI, a mixture containing 15 per cent toluene and 85 per cent octane yields an extraction equal to 14.5 per cent of the entire volume. The index of this extraction denotes 86.8 per cent toluene. This is a little better extraction than can be obtained from a kerosene-toluene mixture which under the same conditions yields a 73.3 per cent toluene in one extraction. By extracting a number of times with small quantities of the solvent, much purer aromatics may be separated.

The effect of extracting with various concentrations of the solvent, keeping the concentration of the mixed oils constant, led to interesting results which should receive discussion. Table VII shows that using a constant mixture of 95 per cent kerosene and 5 per cent toluene, and increasing the amount of sulphur dioxide added from 50 per cent to 85 per cent, the amount dissolved increased to a maximum of 20 per cent with 80.5 per cent solvent. Further addition of sulphur dioxide effected no further dissolving. A marked peculiarity in behavior, however, was noticed on 50 per cent mixtures of kerosene and toluene with increasing addition of solvent. With 27 per cent solvent the mixture was completely soluble. As the amount of solvent increased, less and less of the mixture dissolved until at 58.3 per cent solvent, a minimum solubility of 62.3 per cent of oil was reached. With further addition of solvent, the solubility increased. This peculiar behavior is also shown by the octane-toluene mixtures and is deemed sufficiently interesting to be shown graphically in Graph III. This retrograde solubility is evidence of the complexity of the aromatic-paraffin-sulphur dioxide system, a three-component system, for starting with a homogeneous system we pass to a heterogeneous system and finally to a homogeneous system again, merely by altering one concentration.

In Tables V, VI and VII, the purity of the dissolved and the undissolved oils can be ascertained by comparing their indices of refraction with the indices of the original oils as given under the heading of each table. For instance, in Table VI, the indices of the undissolved oils, in each case, are very close to the value for the pure octane, i.e., 1.3999, showing that virtually all of the aromatics have been removed .

In the experiments on the solubility of pure naphthenes, it was found that only a slight amount of this type hydrocarbon dissolved when less than 50 or 60 per cent of sulphur dioxide was used. It will be recalled that their solubility increased rapidly as the amount of solvent reached 75 to 80 per cent. It seemed probable, therefore, that aromatics which are completely miscible with sulphur dioxide, might be separated from the naphthenes if the percentage of solvent was kept low. The results given in Tables VIII and IX show this to be true. From a mixture containing only 10 per cent benzene and 90 per cent naphthenes it was possible to separate almost pure benzene, using equal volumes (50 per cent) of the solvent. The 15 per cent benzene mixtures also show a fairly good separation. But as the benzene content of the starting mixture increases, the sulphur dioxide-benzene mixture seems to form a solvent for the naphthenes, so that with 50 per cent aromatics present, the naphthenes are entirely miscible with 50 per cent sulphur dioxide. This is analogous to the solubility of paraffins in aromatics-sulphur dioxide mixtures. The xylene-naphthene mixtures (Table IX) show by comparison of the indices of refraction with the original oils, fairly satisfactory separations. In this case, as in the aromatic-paraffin separations, cleaner separations are possible with smaller amounts of xylene in the mixture. This is due to the solvent action of naphthenes of the xylene-sulphur dioxide complex, which is strengthened with increasing proportions of the aromatic. In no case in the naphthene-aromatic work was there noticed the peculiar retrograde solubility shown by the paraffin-aromatics.

C.—Paraffin-Olefin Mixtures

Hexane-Hexylene, Table X.

Pentane-Amylene, Table XI.

Pure olefins are entirely miscible with sulphur dioxide, while paraffins are insoluble. Tables X and XI show that olefins may be separated rather closely from mixtures which are not richer in olefins than about 20 to 25 per cent. In mixtures richer than 25 per cent the olefins and sulphur dioxide act as a solvent for the paraffins so that with 50 per cent olefins we have homogeneous systems formed. For paraffins containing under 20 per cent olefins, however, the indices of refraction show very good separations. The refining of gasolenes and kerosenes to free from unsaturated hydrocarbons is readily accomplished by liquid sulphur dioxide since in natural petroleums the percentage of olefins rarely is over 10 or 15 per cent, and usually not so high.

D.—Paraffin-Naphthene Mixtures

Nonane-Cyclohexane, Table XII.

Gasolene-Naphthenes (75 deg. — 155 deg.), Table XIII.

Gasolene-Naphthenes (175 deg. — 200 deg.), Table XIV.

Paraffins (175 deg. — 200 deg.)-Naphthenes (175 deg. — 200 deg.), Table XV.

Although the literature[5] on sulphur dioxide refining of oils states that naphthenic hydrocarbons are as insoluble in sulphur dioxide as the paraffins and remain undissolved with them after the aromatics and unsaturateds are removed, the present work on individual naphthenes indicates that these hydrocarbons may be entirely dissolved, providing sufficient solvent is added. This solubility curve takes a sharp rise when about 85 per cent of the solvent is added, indicating the formation of a chemical complex. The crystals formed at about this concentration offer further evidence in support of this assumption.

Since this difference in solubility exists, the separation of naphthenes from paraffins was investigated, with a satisfactory degree of success as shown in Tables XII, XIII, XIV and XV.

[5] Cf. Edeleanu (loc. cit.) and Browery (loc. cit.)

Comparing, in these tables, the index of the dissolved and undissolved portions with the indices of the original oils, we find in every experiment considerable separation and in certain cases very close separation. It will be noticed that when only an equal quantity of solvent was added no separation occurred, but that the solubility of the naphthenes was marked when over 80 per cent solvent was used. Thus, in Table XII, when to a mixture of 15 per cent cyclohexane in 85 per cent paraffins, 86.7 per cent sulphur dioxide was added, a separation of 15 per cent oil took place. The index of this soluble portion was 1.4205 compared with 1.4255 for the pure cyclohexane, a very satisfactory separation. The other tables show equally good separations for mixtures containing up to 25 per cent naphthenes. Above this percentage separations are not as clean cut, the paraffins tending to dissolve in the naphthene-sulphur dioxide system.

—15°	85	15		13	1 4450	1 4282

Table XIII gives the results of a run on 150 cc. of mixture containing 15 per cent of naphthenes boiling

from 175 deg. to 200 deg., and 85 per cent of paraffins of the same boiling point. In one treatment, using twice the volume of solvent as of oil, 13 per cent of the oil dissolved. The index of this portion showed almost pure naphthenes.

Heretofore there has been no method of separating naphthenic from paraffin hydrocarbons. The determination of such a mixture in the past involved fractionation to one or two degrees and analysis of the carbon and hydrogen content. Liquid sulphur dioxide, therefore, may prove a valuable aid in such a determination, particularly as the naphthenes are recovered and may be used for further physical and chemical tests. Moreover, since naphthenes have been regarded as the best lubricants of all hydrocarbons, the separation of these, almost pure, may prove of commercial value in the refining of such oils.

—18	50.0	50.0	50.0	50.0	100.0

(a) Olefin-Naphthene Mixtures. For this separation was used a mixture of octylene (index 1.4145) and naphthenes boiling between 75 deg. and 155 deg. (index 1.4267). The results are shown in Table XVI. Using a volume of solvent equal to the volume of oils, it was possible to make very close separations on mixtures containing as high as 50 per cent olefins. The separation of practically pure olefins from naphthenes is possible with sulphur dioxide, providing that not higher than 50 per cent of the solvent is used. This percentage of solvent must not be greatly increased since the naphthenes themselves become appreciably soluble with increasing amounts of sulphur dioxide.

(b) Olefin-Aromatic Mixtures. Olefins and aromatics are each entirely miscible with liquid sulphur dioxide, and, as would be expected, their mixtures in different proportions were entirely soluble. These runs are shown in Table XVII.

F.—Paraffin-Aromatic-Olefin Mixtures

Separation of Gasolene, Xylene, Octylene, Table XVIII.

Table XVIII gives the result of adding equal volumes of sulphur dioxide to gasolene containing varying proportions of xylene and the olefin octylene. The latter two, when present to an extent not exceeding 25 per cent of the volume of the oil, could be quite readily and almost completely removed as the refraction indices of the separated oils indicate. It is this separation which can be very usefully applied to the refining of American petroleums since the aromatics and olefins

TABLE XVIII.—PARAFFIN-AROMATIC-OLEFIN MIXTURES

—18	50.0	33.3	16.7	50.0	50.0	100.0	.....	.....

are considerably below the 25 per cent limit. Moreover, the olefins and aromatics are readily recovered from the sulphur dioxide, a fact which is in marked contrast with the present oil-refining losses due to the removal of unsaturateds with sulphuric acid.

As the percentage of aromatics and unsaturateds exceeded 25 per cent of the mixture, the solubility of the paraffins became more marked. With 50 per cent aromatics and olefins present, the mixture was entirely miscible with the solvent.

This separation was checked up on crude unwashed Pennsylvania gasolene and kerosene. In each case the sulphur dioxide dissolved more than was removed by the sulphonation for olefins and nitration treatment for aromatics. The index of the oil treated with sulphur dioxide showed much purer paraffin hydrocarbons remaining, while the dissolved olefins and aromatics were recovered.

Summary

1. The solubilities of a number of pure aromatics, pure paraffins, pure olefins and naphthenes in liquid sulphur dioxide have been determined for various concentrations.

2. Naphthenes, which the literature states are insoluble, may be completely dissolved in sufficient quantities of the solvent.

3. In order to investigate the utility of the liquid sulphur dioxide method for oil refining and also for analytical work, a number of separations were attempted on mixtures of the above types of hydrocarbons in various proportions. It has been found that within certain limiting concentrations,

a—aromatics may be separated from paraffins or naphthenes

b—olefins may be separated from paraffins or naphthenes

c—aromatics and olefins together may be separated from paraffins or naphthenes

d—naphthenes may be separated from paraffins.

4. The application of the liquid sulphur dioxide method to analytical work on oils is of importance since the separated unsaturateds or aromatics may be recovered and their identity proven by further physical tests. In sulphonation for olefins and nitration for aromatics these oils are lost. Moreover, naphthenes may be separated from paraffins within prescribed limits, a fact that will appeal to the oil analyst.

5. The application of the sulphur dioxide method to oil refining may prove of importance since the valuable aromatics and unsaturated hydrocarbons are recovered, the refined oil is purer than the acid method yields, and the sulphur dioxide may be applied and recovered in a continuous cycle.

Standardization of Base-Metal Thermocouples*

By PAUL D. FOOTE, T. R. HARRISON and C. O. FAIRCHILD
United States Bureau of Standards

A FORM of furnace especially adapted to the rapid testing of a large number of couples consists of a tube of pure nickel or nickel-chromium alloy (chromel) clamped between two water-cooled terminals. A heavy current from a suitable transformer is passed through the tube, the tube itself serving as the heating element or resistor. For use with base-metal couples a porcelain insulating tube may be placed inside the metal tube or the base-metal couple may be wound with asbestos cord to electrically insulate it from the walls of the tube. In this case the standard couple, insulated in a non-porous porcelain tube, is placed with its hot junction as near as possible to the hot junction of the base-metal couple. Rare-metal couples may be standardized by taking proper precautions to prevent contamination by the metal vapors from the heating unit. The heating tube of this furnace is exposed to the air and no thermal insulating material is employed. A large concentric tube may be mounted around the heating tube to reduce the radiation loss, although this is not necessary. A furnace of this type may be heated very rapidly to any temperature up to 1100 deg. C. and it is possible to completely calibrate a couple at 5 or 6 different temperatures in a half hour.

Calibration of Base-Metal Couples

It is difficult to secure equality of temperature between the hot junctions of two base-metal couples or between a base-metal and a rare-metal couple. One arrangement for precision calibration is to place the junction of the rare-metal couple in a small saw-cut made in the hot junction of the base-metal couple and pinch the jaws of the saw-cut until good thermal contact is secured. The rare-metal couple is protected by porcelain tubes to within a few millimeters of the hot junction and the end of the porcelain tube is sealed to the couple by a small amount of kaolin and water-glass cement. This prevents contamination of the rare-metal couple with the exception of the small length of 2 or 3 mm. which is necessarily exposed to the metal vapors. If the furnace is uniformly heated in this region, a small amount of contamination will not cause any error. The method however is not feasible for work on a large scale.

Use of a Muffle Furnace

Several base-metal couples and the standard rare-metal couples mounted in non-porous porcelain tubes are packed together as closely as possible and tied into a bundle with asbestos cord. The hot junctions are inserted into a length of very heavy iron pipe capped at one end, and the open end from which the couples protrude is tightly packed with asbestos wool. The iron tube and couples are mounted in the furnace and the electromotive-force measurements are made as soon as temperature equilibrium is reached. If the muffle furnace is large enough, the iron tubes protecting the base-metal couples need not be removed. A satisfactory size of furnace measures 8 in. by 8 in. by 30 in. deep. Precision work is impossible in this method of calibration. Even when every precaution is taken to reduce temperature gradients, differences in temperature of 10 deg. or 20 deg. C. frequently will be found to exist between the different couples mounted side by side. However, this accuracy is sufficient for many industrial processes.

Use of Molten Metal Bath

The most satisfactory method for calibrating base-metal couples on a large scale is by use of a bath of molten metal. An iron pot about 12 in. diameter or larger and 15 in. deep is filled with tin covered with powdered graphite. This may be heated in a gas furnace or an electric furnace wound with nickel alloy such as nichrome or chromel. Into the tin bath dip about six iron tubes closed at the lower end and immersed to a depth of 12 in. The tubes are just large enough to permit easy insertion of the base-metal couple with its iron protecting tube. The standard couple is mounted in one of the six tubes and the base-metal couples are placed in the others. As soon as temperature equilibrium is reached the electromotive forces are measured, that of the standard couple giving the temperature of the bath. A large number of base-metal couples may be tested one after the other at this temperature and the process is then repeated at another temperature. The tin bath may be used satisfactorily in the range 300 deg. C. to 1000 deg. C. since tin is a metal of low volatility.

The method may be improved by operating the furnace and standard couple in connection with a temperature-control apparatus so that the temperature of the bath remains constant during a series of measurements. This advantage, however, is offset by the extra expense and complication of additional apparatus and in general is unnecessary. Data obtained by the above method are plotted, temperature versus electromotive force, for each couple, and a smooth curve drawn representing the calibration. For some types of base-metal couple the curve is slightly S-shaped showing small inflections near the critical points of the metals of which the couple is constructed. In precision work the calibration must be made at short temperature intervals over these critical regions to determine the exact form of the temp.-emf. curve.

Single Point Calibration or Check Point

It is frequently desirable to check a base-metal couple at a single point. If the couple is reading electromotive forces say 2 per cent higher at this temperature than the usual electromotive force or that shown by the

* The second of a series of two articles dealing with the pyrometer laboratory for industrial purposes. The first article dealt with rare-metal thermocouples.

original calibration data it is customary to assume that it reads 2 per cent high at all temperatures. This method of calibration at best is only approximate and experimentally it is frequently found that a couple reading 2 per cent high at 800 deg. C. indicates correctly at 1000 deg. C. However, single point calibrations are of value especially as a check upon the behavior of any particular couple.

A convenient standard temperature for this work is the melting or freezing point of sodium chloride (common salt), chemically pure. This material melts or freezes at 801 deg. C. The salt may be used in a nickel or duriron crucible heated in a gas or electric furnace. The base-metal couples are immersed several inches in the bath and melting or freezing point curves observed as discussed in a previous article.[1] If the salt has not been previously fused, it must be melted the first time with a cover on the crucible as the imprisoned water in the salt crystals will cause the salt to sputter out badly. After the first melt, however, there will be no trouble in the use of this material. Molten salt reacts somewhat with most base-metal couples but the reaction is so slow that the couple will not be injured. The Bureau has not found any serious change in melting point resulting from heating the salt in contact with iron for several hours.

Calibration of Thermocouples with Millivoltmeter or Indicating Instrument

When a thermocouple in a furnace is connected to a millivoltmeter, the electromotive force of the couple causes a current to flow around the circuit, which, in accordance with Ohm's law is equal to e/R where e is the electromotive force developed by the couple and R the total resistance of the circuit. The deflection of the pointer of the millivoltmeter is aproximately proportional to this current. Thus if the temperature of the furnace remains constant e is constant but the deflection of the instrument will be altered by changes in the resistance R. Hence any variation in R which produces a change in the reading of the instrument would be interpreted as a change in the temperature of the furnace although actually this is constant. The total resistance of the circuit may be divided into three parts, R_g the resistance of the millivoltmeter, R_L the resistance of the line, and R_c the resistance of the couple. If these resistances are properly proportioned the effect upon the reading of the indicator of any changes in the resistance R likely to occur can be reduced to practically zero. This condition is realized when R_g, the resistance of the galvanometer, is sufficiently high compared with $R_c + R_L$, the resistance of the external circuit. Suppose that the indicator has an electromotive force scale graduated to read the potential difference at its terminals. The relation between the reading of the instrument e_o and the true electromotive force e of the couple to which it is connected is given by the following equation:

$$e_o = \frac{R_g}{R_g + R_c + R_L} e$$

Thus if R_g is very large compared to $R_c + R_L$ the ratio $R_g/(R_g + R_c + R_L)$ is practically 1 and the reading of the galvanometer gives the true electromotive force of the couple.

[1] This journal, Apr. 1, 1918, p. 343.

Robust indicators are now obtainable having a resistance of 300 to 1200 ohms. As a particular example of the behavior of such an instrument, values of the factors occurring in the above equation will be considered for an actual thermocouple installation.

Galvanometer resistance $= R_g = 300$ ohms
Couple resistance $= R_c = 1$ ohms
Line resistance $= R_L = 1$ ohms

Whence

$$e_o = \frac{R_g}{R_g + R_c + R_L} e = \frac{300}{300 + 1 + 1} e = 0.993e$$

Thus, if the galvanometer is graduated to read potential differences at its terminals, the reading of the instrument gives the true electromotive force of the couple to within 0.7 per cent.

The construction of an indicator having a resistance of 300 ohms or more and having the necessary characteristics of robustness, portability, constancy in calibration, etc., is somewhat difficult. For this reason many manufacturers have secured these latter characteristics at a sacrifice of the desirable feature of high resistance. Instruments having a resistance of 10 ohms or less are in extensive use. Suppose a galvanometer, 10 ohms in resistance, calibrated to read potential differences at its terminals, is used in the circuit described above.

$$e = \frac{R_g}{R_g + R_c + R_L} e = \frac{10}{10 + 1 + 1} = 0.83e$$

Thus, if the galvanometer is graduated to read potential differences at its terminals, the electromotive force indicated by the instrument would be 17 per cent less than the true electromotive force of the couple. Such large errors are compensated for by arbitrarily graduating the scale to read the electromotive force of the couple when the resistance of the couple and line has a certain fixed value, in the above example 2 ohms. The instrument will accordingly read correctly for this external resistance but will read in error if the external resistance is altered. Bad contacts, deterioration of the couple from oxidation, change in depth of immersion, temperature coefficient of the copper lead wires, etc., may at any time alter the resistance of the external circuit. Let us compare the behavior of the 300-ohm instrument and the 10-ohm instrument, assuming both instruments are compensatingly graduated to read correctly for an external resistance of 2 ohms, when for one of the several reasons cited above the external resistance is increased by 1 ohm.

If the galvanometer were graduated to read potential differences at its terminals the relation between its reading e_o and the true electromotice force of the couple e would be given by the equation above. The instrument may be compensated so that its new reading, say e_o' is correct for some definite value of the external resistance. Inverting the former equation and putting $R_c + R_L + R' =$

$$e = \frac{R_g + R'}{R_g} e_o$$

It the compensated calibration is correct when $R' = R_o'$, then

$$e_o' = \frac{R_g - R_o'}{R_g} e_o$$

The per cent error in the reading e_o' due to a change

in R^1 is obtained by differentiating the following equation:

$$e_o^1 = \frac{R_g}{R_g + R^1} e_o$$

where R^1 is now a variable.

Per cent error in reading for change in R^1 of 1 ohm $= \frac{100 de_o^1}{e_o^1} = \frac{100 dR^1}{R_g} \frac{e_o}{e_o^1} = \frac{100 dR^1}{R_g} \frac{R_g + R_o^1}{R_o^1} = \frac{100(1)}{300 + 2} =$ 0.33% for 300 ohm indicator = about 3° at 1000° C. and $\frac{100(1)}{10 + 2} = 8.3\%$ for 10 ohm indicator = about 80° at 1000° C.

Thus when both instruments read correctly for an external resistance of 2 ohms, if the external resistance is increased by 1 ohm, the low resistance indicator is in error by 8.3 per cent while the high resistance instrument still reads practically correct. Considerations such as the above emphasize the importance of using a galvanometer having a resistance of 300 ohms or more. In actual operation the line resistance may change by several ohms on account of bad contacts and deterioration of the thermocouple.

The varying factor of line resistance has proven a strong argument in favor of a potentiometric method of measuring thermocouple electromotive force. A number of instruments based upon this principle are available. Besides the portable and laboratory types of potentiometer made by Leeds and Northrup there are special potentiometric galvanometer systems such as the pyrovolter made by the Pyrolectric Instrument Company, the Brown Heat Meter made by the Brown Instrument Company, and the Alladin made by Wilson-Maeulen. The high resistance galvanometer, however, is accurate enough for most purposes and possesses the advantages that it is less costly than the above instruments and that it indicates temperature continuously with no preliminary adjustments, while potentiometer installations require zero adjustments or balances on the standard cell, and except in the recording and deflecting potentiometers, a dial must be moved to obtain a setting.

Usually indicators are graduated to read temperature directly and do not have an electromotive-force scale. In this case they must be used with the type of couple for which the scale was designed. If the instrument has a resistance of more than 100 times the resistance of the external circuit no particular attention need be given to slight deviation from the prescribed resistance of the couple. The temp.-emf. relation of the couple for which the scale of the instrument is designed can be secured from the maker or can be determined in the laboratory by calibrating one of the couples as previously described.[3] The temp.-emf. relation can be also obtained directly from the temperature scale of the indicator by measuring with a potentiometer the potential drop across the terminals of the indicator when sufficient current is flowing through it to deflect the pointer to various scale readings. The reading of the potentiometer is equal to the emf. of the couple corresponding to a hot junction temperature given by the scale reading of the indicator and a cold junction temperature given by the reading of the indicator on open circuit. The various couples to be used with this instrument may be calibrated in the laboratory by use of a potentiometer. If the temp.-emf. relation of each couple agrees closely with that of the standard temp.-emf. curves, the couples are satisfactory to use with this indicator without applying corrections.

Suppose one particular couple develops 30 millivolts at 1000 deg. C. while the standard reference couple for which the instrument was calibrated develops 30 millivolts at a temperature of 1030 deg. C. The first couple will accordingly read too high by 30 deg. C. when corrected to the indicator. Proceeding in this manner a correction table can be prepared for each couple showing a temp.-emf. relation much different from that of the reference couple. It is of course possible to calibrate in the laboratory the couple and high resistance indicator as a unit. This, however, is not always convenient, especially if the indicator is of the wall type or is in constant use.

The calibration of couples for use with an indicator of low resistance can be made in the manner described above or the couple and indicator with lead wires of the same resistance as that used in the permanent installation may be calibrated as a unit. In the first method great care must be taken to see that the line resistance of the finally installed couple is correct. Manufacturers obtain the correct resistance by the use of a coil of resistance wire in series with the couple and mounted in the head of the couple. By properly adjusting the extra resistance slight deviations in the temp.-emf. relation for any particular couple from that of the reference couple for which the scale of the indicator was designed, may be partially corrected for. It is scarcely advisable for the industrial plant to make adjustments of this character. If low-resistance indicators are employed it is probably better to purchase of the manufacturer couples adjusted for a specified line resistance and for the particular indicator.

In the use of low-resistance indicators the resistance of the line and couple should be frequently checked. The resistance may be measured by means of a "test set" or portable Wheatstone bridge. Obtain a setting for resistance in the usual manner, then reverse the + and — terminals of the line and obtain a second setting. The mean of the two resistances gives the correct resistance of the circuit. The two settings will be different because of the electromotive force developed by the couple. Another method of measuring the resistance of a couple while hot, is given in Bureau of Standards Scientific Paper No. 250, page 147 .

Checking Thermocouples in Fixed Installations

It is frequently desirable to check the readings of a thermocouple without removing it from the furnace in which it is installed. Tests of this nature are of extreme importance in the technical industries. They are also difficult to perform with precision and the precision which is obtainable in a laboratory test can not be expected in tests of this nature. However, an ordinary calibration, in the laboratory, of a base-metal couple which has been in use in a fixed installation for some time, while furnishing results apparently of high precision, does not necessarily hold when the couple is returned to its original installation. This is on account of the heterogeneity developed in a base-metal couple after prolonged heating.

[3] This journal Apr. 1, 1918, p. 343.

The presence of heterogeneity could be detected by a homogeneity test but such tests on a large scale are not worth while for base-metal couples and moreover do not show how to correct the readings satisfactorily. Such a test would simply indicate that the couple should be thrown away whereas in its permanent installation it still has a useful life. The throwing away of base-metal couples in a fixed installation as soon as heterogeneity sets up would be a very costly and unnecessary procedure except in the comparatively rare cases where the highest possible accuracy is required. The degree of heterogeneity developed depends upon the type of installation, depth of immersion, location and character of temperature gradient, etc. These quantities are fairly definite and fixed for any particular installation. If, however, the couple is removed from the installation and calibrated in the laboratory these quantities are altered and the conditions under which the couple is actually operating can not be reproduced. The calibration in the laboratory may give results quite different from the calibration which would be obtained if it were possible to duplicate exactly all the physical characteristics of the permanent installation. Hence it is evident that if non-homogeneous couples are ever to be used, it is important that they be calibrated or checked in their fixed installation.

The exact method of procedure depends upon the type of installation. A standard checking couple is employed complete with a high-resistance galvanometer or portable potentiometer. The hot junction of the checking couple is placed as closely as possible to the hot junction of the couple under test and the readings of the two couples compared. The main objection to the method is the difficulty in getting the two hot junctions together. One method is to drill a hole in the furnace at the side of each couple permanently installed large enough to permit insertion of the checking couple. The hole is kept plugged except when comparison tests are being made. The checking couple is immersed in the furnace through this hole to the same depth as the couple under test. The hole should be located as close to the permanently installed couple as possible.

In many installations the base-metal couple and protecting tube are mounted inside another protecting tube of iron, fire clay, carborundum, or some other refractory which is permanently cemented or fastened into the furnace wall. Frequently there is room to insert a small test couple in this outer tube along side of the fixed couple. A third method, much less satisfactory, is to wait until the furnace has reached a fairly constant temperature and make observations with the couple under test, then remove this couple from the furnace and insert to the same depth the checking couple.

If desired, comparisons can be made preferably by either the first or second method at several temperatures and a curve may be obtained for each permanently installed couple showing the corrections necessary to apply to its readings.

It may be argued that this method of checking couples is unsatisfactory because in most furnaces used in industrial processes large temperature gradients exist and there is no certainty that the standard couple is at the same temperature as the couple under test. This objection, however, is not serious because if temperature gradients do exist, in the furnace, of such a magnitude as to cause much difference in temperature between two similarly mounted thermocouples, located closely together, the accuracy required by the measuring instruments need not be great, and the reading of the standard couple can be accepted for the standardization of fixed couple just as satisfactorily as if the true temperature of the fixed couple were known. If temperature gradients exist of such a magnitude that two correctly calibrated couples similarly mounted closely together read say 20 deg. C. apart, it may be certain that neither couple is registering the temperature of material within the furnace to this degree of accuracy.

Depth of Immersion of Thermocouple

Thermocouples immersed in furnaces of the various industrial types must be carefully protected. Heavy iron tubes and frequently larger auxiliary protecting tubes of various materials are employed. The thermocouple calibrated in the laboratory will give the temperature of the hot junction when installed in the protecting tubes but there is no certainty that this temperature is that of the furnace. Conduction along the protecting tubes may be so great that the temperature of the couple is far below that of the furnace. Conduction losses affecting the temperature of the hot junction may be reduced and even eliminated by using a sufficient depth of immersion but it is not always possible to do this and it is difficult to determine when the depth of immersion is sufficient. For example, an immersion of 5 cm. might be satisfactory for one type of furnace, or for a molten bath, and 30 cm. insufficient for a certain muffle furnace.

Each particular case requires special consideration.

The general practice is to use as deep immersion as is conveniently possible and trust that this is satisfactory. Two methods may be suggested for investigating the question but neither one is very conclusive. First, remove the couple alone from the fixed installation leaving all protecting tubes in place. If it is impossible to remove the iron tube from the couple use a similar tube in the fixed installation without the couple. Explore the temperature inside the protecting tube with an unprotected couple. If the temperature for several centimeters along the axis of the tube at the inner end is practically uniform, the depth of immersion is satisfactory. If, however, the temperature falls rapidly in this region the immersion is not deep enough. Second, the couple previously standardized is mounted complete in the fixed installation and compared with another checking couple mounted as previously discussed. The checking couple must have a small cross section and must be used either unprotected or protected by an extremely thin tube in order to minimize the loss of heat by conduction. The hot junctions of this couple and of the couple under test are brought closely together but not in contact. The checking couple should indicate a temperature more nearly that of the furnace than the temperature observed with the fixed couple. If the temperature difference between the two couples is large a greater depth of immersion should be employed. These methods are complicated by local variations in the temperature of the furnace but checks of this nature, although somewhat unsatisfactory, are better than no checks at all.

In an ordinary uncompensated thermocouple the

electromotive force developed depends upon the temperature of the cold junctions as well as upon the temperature of the hot junction. For some base-metal couples, having a linear relation between temperature and electromotive force, the electromotive force is proportional to the difference in temperatures of the hot and cold junctions. With such couples a change of 10 deg. C. in the temperature of the cold junctions, unless corrected for, would result in an error of 10 deg. C. in the temperatures indicated by the couples. Convenient methods for obtaining these corrections where the couple is used with the cold junctions at a temperature different from that for which it was calibrated are discussed in Bureau of Standards Scientific Paper No. 202. The following rules may be observed:

If a thermocouple has been calibrated with cold junctions at 0 deg. C. and is used with the cold junctions at t_0 deg. C. add to observed electromotive force the value of the electromotive force developed when the hot junction is at t_0 deg. C. and the cold junctions are at 0 deg. C. The original calibration then applies.

The corrections may be expressed in terms of degrees as follows: If a thermocouple has been calibrated with the cold junctions at 0 deg. C. and is used with the cold junctions at t_0 deg. C., add to the observed temperature the quantity $F \times t_0$ deg. C., where F is a factor depending upon the type of couple employed and upon the temperature of the hot junction. The value of F varies from 1.5 to 0.3 for base-metal couples but for rough work it may be assumed equal to 1.0. The correct values may be obtained by the method described in the paper referred to above. For a platinum, platinum-rhodium couple F has the values given in the following table:

Platinum, Platinum-Rhodium Couple. Calibrated at Cold Junction = 0°C.

Temperature of Hot Junction	F.
400°C.	0.61
800	0.54
1,200	0.47
1,400	0.45

A convenient method for applying these corrections is to set the indicator or galvanometer on open circuit to read the cold junction temperature. When this is done the above corrections are taken care of automatically, so long as the cold junctions remain at this temperature. Some types of indicators, especially the portable potentiometers, have a special adjusting dial for thus correcting for the cold junction temperatures. Bureau of Standards Scientific Paper No. 202 describes the method of correcting when the couple has been calibrated with a cold junction temperature of t_c deg. C. or t_f deg. F. and is used with a cold junction temperature of t_0 deg. C. or t_0 deg. F.

The importance of the control of the cold junction temperature is evident from the above discussion. Various devices are used to this purpose. The cold junction may be buried 8' or 10 ft. under ground at which depth the variations in temperature are scarcely ever more than 5 deg. C. throughout the year. The cold junctions may be maintained at 0 deg. C. by the use of ice boxes as discussed in a previous article (Apr. 1, 1918), although this method is not practical for a large industrial installation. Another method is to water-jacket the head of the couple allowing a small stream of water from the water main to flow through the jacket. Still another method in use is to lead wires of the same material as the couple from the couple to a cold junction box the temperature of which is thermostatically controlled. In all of these methods the couples are calibrated for the proper cold junction temperature.

In order to avoid the necessity of controlling the temperature of the cold junction near a furnace where the variations in room temperature are extreme, several methods of automatic compensation are in extensive use, such as balancing the decrease in electromotive force caused by an increase in the temperature of the cold junction by an external electromotive force from a battery. In this case an electrical circuit arranged in the form of a Wheatstone bridge is employed. Another method is the use, in the head of the couple, of a shunt and a series resistance, the latter having a zero temperature coefficient. Both of the methods give only partial compensation but by proper adjustment the compensation is accurate enough for most industrial work. The former method is usually effective over a much wider range of hot junction temperatures than the latter, which has its principal application for work in the neighborhood of the temperature for which it is arranged to give best compensation. In this temperature range the method is more desirable than the Wheatstone bridge method because no outside battery is required. Furthermore, in the latter method the degree of compensation depends upon the condition of the battery so that some attention is required to see that the battery is never run down.

A very simple method which is inexpensive, accurate, and convenient is the use of compensation lead wires from the couple to the indicator. Frequently the indicator or recorder is located in a room, at some distance from the furnace, where the temperature does not vary seriously. By means of the compensating leads the cold junction is moved from the head of the couple to this room and hence can be maintained at a fairly constant temperature. In the case of the base-metal couple the leads may be of the same material as the couple. The cost of platinum prevents such practice for rare-metal couples. However, inexpensive lead wires of copper and an alloy of copper-nickel are now available for use with the platinum, platinum-rhodium couple. Lead wires of this type have been tested at the Bureau of Standards and found to be very satisfactory, in fact the compensation is closer than 5 deg. C. for a variation in temperature of the couple-lead wire junctions of 200 deg. C. or more. Compensating lead wires for either base-metal or rare-metal couples may be carried from the couple to a cold junction box or to a pipe buried in the ground at some distance from the furnace. In this manner practically perfect control of the cold junction temperature is obtained.

Method of Making Thermocouple Junctions

The hot junction of a thermocouple should be made by soldering or fusing the two metals. Silver solder is useful at temperatures below 900 deg. C. or gold below 100 deg. C., but in general the best type of junction is made by fusion. The junction of a rare-metal couple may be made by use of a small oxygen illuminating-gas flame. Acetylene is not desirable. Special blast lamps suitable for this work are obtainable. The flame should be small, possibly 4 cm. long, the tip of

the lamp having an opening of from 0.5 to 1 mm. The junction should be fused into a ball about 1 mm. in diameter.

Another convenient method of fusing the junction is by use of an electric arc. One of the couple wires is connected to the positive terminal of the 110 volt d.c. main and the negative terminal is connected through a resistance to a graphite pencil having an insulating handle. The graphite should be about 5 or 6 mm. in diameter and should be sharpened to a point. For a couple of 0.6-mm. wire, a resistance of 30 to 40 ohms is used. Touch together the ends of the two wires of the couple and then bring the point of the graphite pencil into contact with the junction. As soon as an arc is formed draw the pencil away. With a little practice excellent joints can be made in this manner.

This method is also good for repairing broken couples. In this case the junction should be made as nearly as possible of the same size as the wire itself.

Large base-metal couples may be fused either by an electric arc or oxygen-gas torch. It is frequently the practice to twist the two wires as shown in Fig. 1 for a few turns as this possibly gives greater mechanical strength. Before fusing, the junction of the couple is coated thoroughly with borax. This is done by heating the ends of the two wires to a dull red heat and then dipping into the powdered borax. The borax adhering to the wire is then melted and the process continued until a heavy coating of the fused transparent borax is obtained. The couple may be mounted horizontally or suspended with the junction down. The arc or oxygen-gas flame is allowed to play upon the junction until the metal fuses into a neat bead. If sufficient borax is used the weld will show no signs of oxidation. The arc employed for this work is of the ordinary type consisting of two carbons, although for small couples the form of arc described above may be used.

No flux should be employed when fusing rare-metal couples.

Do not allow borax to come in contact with the porcelain lining of a furnace or with porcelain tubes. What borax remains on a base-metal couple may be removed if desired by dipping the junction while hot into water. The borax glass will then crack away. In making thermocouple junctions dark glasses should be worn in order that the work may be watched closely. It is also essential that the glasses absorb the ultra-violet light which may cause severe burns and injure the eyes. Special goggles for this type of work are advertised in the trade journals.

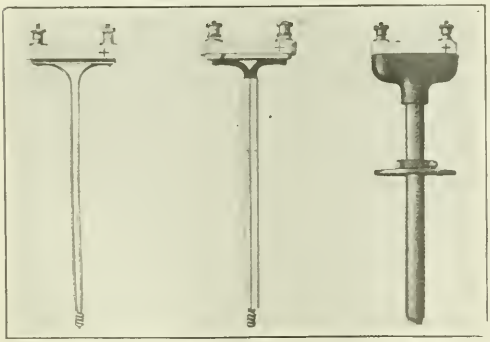

FIG. 1. TYPICAL FORM OF BASE METAL COUPLES. NOTE THE TWISTED WIRES AT WELDER JUNCTION.

Construction of Base-Metal Couples

A company using large numbers of base-metal couples can profitably construct them from wire furnished by the manufacturer instead of purchasing completely mounted thermocouples. For temperatures up to about 900 deg. C., iron versus constantan is suitable. For temperatures up to 1100 deg. C. special-patented alloys are obtainable such as chromel versus alumel. Wire for the construction of the above couples may be purchased in coils of various gages, (usually No. 6 or No. 8) and all couples made from any two coils will have very nearly the same calibration if special attention has been given by the manufacturer to the securing of homogeneous material. Wire for this purpose is advertised in the trade journals. To make a couple, cut off the desired length for each wire and fuse the junction as described above. The two wires are insulated by fire clay or porcelain insulating tubes and are then mounted in a steel or other type of protecting tube. For certain types of work thermocouple wire insulated with asbestos is useful. Wire may be procured insulated in this manner, or the insulation can be put on in the laboratory. There are two methods of doing this, one by the use of asbestos sleeving and the other by use of asbestos cord. Samples of these materials can be secured from dealers in asbestos goods. The cord is wound back and forth across the two wires in a figure 8. After the asbestos is in place it is good practice to fill the spacing between turns with a refractory cement such as ground alundum and water glass. Several pyrometer manufacturers sell cements already mixed for this purpose. Couples protected in this manner can be used for many processes without the outside iron protecting case.

Maintaining Laboratory Records

One of the most serious faults of an industrial laboratory is the failure to maintain satisfactory records. All calibration data, operation, costs, etc., should be recorded and filed for ready reference. Companies using several hundred or thousand couples per year should be able to state definitely whether iron-constantan couples will serve their purpose as well as the more expensive nickel-alloy couples. For any particular process, will the longer life of the more expensive base-metal couple justify its installation for temperatures around say 900 deg. C.? For operation at 1100 deg. C. will the longer life of the still more expensive platinum couple justify its installation? A couple which is used at temperatures high enough to seriously shorten its life is liable at any time to develop inhomogeneity affecting its calibration. Is this question of accuracy of sufficient importance for any particular process to justify equipping with more expensive couples? What is the life of the various couples used at different temperatures expressed in hours per dollar of cost?

Many types of protecting tubes for base-metal couples are available such as fire clay, carborundum, duriron, nichrome, and steel. What is the most economical tube to use reckoned on a basis of life in hours per

dollar? What depth of immersion gives the most satisfactory results for any particular type of installation?

Fused quartz or silica tubes for rare-metal couples do not break as easily as porcelain when subjected to changes in temperature. On the other hand, quartz is not very satisfactory above 1100 deg. C. Which type of protecting tube is found to be more satisfactory for any process in question? Is the factor of variable lead resistance and change in resistance of the couple upon deterioration of sufficient importance to justify a potentiometric installation for any particular process? What is the best method of checking couples in a certain fixed installation? What method is found by experience to be the most satisfactory for controlling the temperature of the cold junctions of the thermocouples?

Are they records made by the recorders, of real service, or are they simply filed away and no attempt made to correlate the data with properties of the finished product? Do the records show that the heating of the furnace has followed specifications and if not what is the best method of remedying this difficulty in the future? Should a method of automatic temperature control or signaling be adopted? Would a bonus system, awarding the furnace operator a certain increase in wages when the temperature of a furnace is maintained within prescribed limits, prove a profitable solution of the difficulty? Would an installation of optical pyrometers serve more satisfactorily than thermocouples for a certain process? Is the disadvantage that optical pyrometers cannot be made recording offset by a decrease in cost of maintenance of thermocouples at extreme temperatures? Would it be economical to hire a man whose sole work would be to observe, with an optical pyrometer, the temperatures of several furnaces? Or should a recording radiation pyrometer be employed?

Many of the above questions have been briefly considered in the present discussion but the most satisfactory answer to these and similar questions can be obtained from a systematic study of all records and data. The suggestions for efficiency should not be pushed to an extreme. It is better to err on the side of extravagance than economy in operating a pyrometer installation. The primary object should be to have a perfect working system of temperature control. However, expenses which the records show to be unnecessary should be curtailed.

Besides aiding in the establishment of an efficient system of temperature control the records are of extreme value for investigational work. In this field the pyrometer engineer must coöperate with the metallurgist and chemist. These latter, for example, find that the product which was heat treated on a certain date possesses certain properties which are especially valuable. It is desired to exactly duplicate the special heat treatment or to possibly alter the method slightly with the idea of producing still further improvements in the product. Investigational work of this character and even more specialized research may be carried on simultaneously with the routine work. The metallurgist, chemist, pyrometer engineer, and all concerned, including the operators of the furnace, will develop increased interest in their work because the spirit of research creates enthusiasm.

Washington, D. C.

Bibliography on the Physical Properties of Copper

By Paul D. Merica
United States Bureau of Standards

IN THE series of four articles on the physical properties of copper and the factors by which they are affected, completed in the last issue of *Metallurgical & Chemical Engineering*, reference was frequently made to original sources of information. Those sources are here presented as a bibliography of the subject. The segregation of references by topics will be found specially useful and convenient.

Chemistry in Japan

DR. ALCAN HIRSCH of New York, consulting chemical engineer to the Japan Dyestuff Mfg. Co., Ltd., and consulting chemist to the pharmaceutical and drug establishment of the Sankyo Co., returned March 19th from Japan. In an interview with Dr. Hirsch by a member of our staff, he said that the coal-tar dyestuff industry in Japan was getting well established and flourishing. The Japan Dyestuff Co., which he serves, is that which was organized under government auspices in 1916, and is much the largest. The second in capacity is the Mitsui Co., which addresses itself to making anthracene products, and there are about ten other small concerns making a limited number of colors.

Among the products of the Japan Dyestuff concern are, as intermediates, aniline, phenol, naphthylamines, toluidines, nitrophenol, tolidine, methyl-anilines, naphthols, H-acid, dianisidine and Micheler's ketone. Among the colors produced on a commercial scale and on the market are benzo fast red A, congo red, benzo purpurine, methanyl yellow, chrysophenine yellow, Nippon direct black, Nissen dark blue, Nissen indigo (type), synthetic indigo, Nippon direct blue, Nissen black, methylene blue, methyl violet and rhodamine B. The Nissen colors are originals, developed in their own laboratories, and are especially designed for Far Eastern requirements. The company also refines its own crudes from by-product coke ovens and makes its own sulphuric acid, oleum, hydrochloric and nitric acids, electrolytic caustic soda and chlorine; and it has a concentrating plant for the recovery of sulphuric acid.

The plant is located at Osaka, on the Ajikawa River, which provides water communication with the Inland Sea and the Pacific Ocean. The crudes are all brought by water transportation. The company employs about 2,000 men. Mr. H. Nakaya is president, the present managing director is Dr. Miyoshi and the general superintendent is Mr. Sakai. Dr. K. Shimomura, the former managing director, resigned on account of ill health, but continues to devote a part of his time to the company in a consulting capacity.

The Mitsui Company confines itself to anthracene products and makes alizarine reds, blues and greens. The native dyestuff industry in Japan is somewhat similar to that in the United States. There is a shortage of cotton vat dyes, they seem to be ahead of us in anthracene products, and the synthetic indigo industry is growing. The prices range comparatively about the same in both countries.

The Sankyo Company makes chiefly pharmaceutical preparations and drugs and it will have a special interest for New York chemists in that Dr. Jokichi Takamine is president. Mr. M. Shiohara is managing director. This plant is located at Shinagawa, and operates the government subsidized pharmaceutical and drug establishment known as Naikoku in connection with its own works. They produce a large number of preparations, including phenol, phenolates and phenol derivatives, aniline, salicylic acid, salicylates (including sodium acetyl salicylate, phenyl salicylate, theobromine sodium salicylate, etc.), acetanilid, phenacetine, cocaine hydrochloride, salvarsan, neosalvarsan, formaldehyde, taka-diastase, chloral hydrate, tuberculin and still more, together with ointments, tablets, pills and compounded medicines.

Dr. Hirsch was full of enthusiasm over the National Exposition of Chemical Industries which was held at Uyeno Park, Tokio, from September to November inclusive, 1917. The government gave its official buildings for the purpose, to which a considerable number were added to provide room for the exhibits. Admission was ten sen (five cents) and all school children were taken

CHEMICAL PLANT OF SANKYO & COMPANY, FUJINAGAWA, TOKYO, JAPAN

to see it. A feature that impressed Dr. Hirsch emphatically was the way in which this exhibition brought chemistry home to the people at large. Artistically it was made very attractive and the uses of products were pictorially represented on back drops in booth structures and with wax mannikins. For instance, the Tokio Gaslight Company had a great pile of coal upon which stood a huge, many-armed-god of fire, fully fifteen feet high. Strands of red gauze were blown up from the coal underneath the figure, which gave an impression of flames. In the hand of each of the many arms was held a pictured plaque, indicating the uses of gas and coal products while ranged in front were many of the products themselves. The use of mannikins in the representations of the many industries gave a human touch to the show that made everyone feel that he understood at least something about it.

It is obvious that the Japanese are resolved to make their chemical industries permanent, and it is doubtful if any method could have been devised to make the people feel it to be a part of themselves more effectively than by their great exposition.

The Design and Operation of a Small Kjellin Furnace*

Manufacture of Electric Steel for Stamp-Mill Shoes and Dies on the Witwatersrand, South Africa

By GEORGE H. STANLEY and W. BUCHANAN

THE design of an induction furnace is very similar to that of a single-phase, core-type, alternating-current transformer, subject to the limitations of non-sandwiched windings and a horizontal position of the secondary. While it is most important with a transformer to generate a minimum of heat and circulate oil or water quickly to carry off the small amount necessarily generated, in a furnace the main object is to convert the maximum of the supplied energy into heat, and prevent its loss by the use of a non-conducting casing.

The action of a current in producing magnetism is of a reciprocal nature. Any change in the number of magnetic lines passing through a closed conducting loop produces an electric current in such circuit, the strength of which is directly proportional to the rate of change of the magnetism, and inversely to the impedance of the circuit. The relation for alternating currents corresponding to Ohm's law for direct currents is

$$E = I\sqrt{R^2 + \omega^2 L^2}$$

where E is the electromotive force,
I is the current produced in amperes,
R is the resistance of the circuit in ohms,
ω is the rate at which the current changes (or angular velocity),
L is the coefficient of self-induction of the circuit.

The coefficient of self-induction of the circuit may be otherwise thought of as the number of magnetic lines produced through a circuit when unit current flows through it.

Conductivity of Secondary

No very precise data appear to be published regarding the electrical resistance of different grades of steel at very high temperatures. It was therefore assumed that the temperature coefficient determined by Fleming and Dewar for pure iron at low temperature would give sufficiently accurate values for molten steel. This coefficient gives the resistance R at any temperature t deg. C., by the relation

$$R = R_0(1 + 0.00625\ t)$$

where R_0 is the resistance at zero Centigrade. The working temperature of the furnace was estimated to be about 1550 deg. C., so the resistance when hot appears to be 10.7 times the value at 0 deg. C.

There is even greater uncertainty regarding the value R_0 for high carbon steel, the resistance of which seems to vary from eight to twelve times that of copper. Ten times the resistance of copper was taken as likely to give an approximate average value, and the specific resistance of the heated metal figured to be $0.64 \times 10.7 \times 10^{-6}$ ohms per cubic inch. The circumference of the channel being 157 inches gives a resistance of 0.0107 ohms per square inch of cross-section. The minimum metal retained in the furnace between heats—900 lbs.—with about 22.5 sq. in. section has a resistance of 0.00048 ohms, while the maximum contents of 2900 lbs. with 72 sq. in. cross-section has a resistance of 0.00015 ohms.

Energy Required

Published data regarding the amount of energy required to melt one ton of steel in the electric furnace show a great deal of variation, depending upon the size and type of furnace. It seems to be the general opinion that the induction type takes rather more power than the corresponding arc furnace, and for the small size considered it appeared as if 900 kw.-hr. would be required per short ton to melt cold steel scrap. As, however, it was intended to pre-heat the scrap in the furnace attached to the mold-drying stove, it was expected that the actual expenditure of electricity per ton of product would be somewhat less than 900 kw.-hr., and the whole plant was designed to be able to give this amount. To supply 900 units every eight hours necessitates an average input of 112.5 kilowatts. Further, since this amount is not possible during the first hour or so when the small quantity of metal in the channel offers a maximum resistance, it becomes necessary to be able to give at least 120 kilowatts continuously with a full furnace. This energy is absorbed with $\sqrt{\frac{120{,}000}{0.00015}}$ or 28,300 amperes, the phase voltage required being

*The second instalment of a combined abstract of two papers: Electric Furnace Manufacture of Shoes and Dies on the Witwatersrand, by Geo. H. Stanley, *Jour.* Chem., Met. and Min. Soc. of S. Africa, Sept., 1917, and The First Electric Steel-Melting Furnace in South Africa, by W. Buchanan, *Jour.* S. African Inst. of Elec. Eng., Sept., 1917. This part of the papers relates to design. Features of operation were presented in the first article.

$28,300 \times 0.00015 = 4.24$ volts. It may be noted that unless the voltage be increased at light load, the energy supplied to the 900 pounds of metal would be 37.5 kilowatts, while it has been found that about 30 kilowatts at full temperature is lost by radiation.

Magnetic Field

One of the most serious drawbacks to the use of the induction type of furnace is its low power factor (down to 0.25) when used with current of the commonly available frequency of fifty alternations. The reason for this is the excessive amount of magnetic leakage caused by the necessary distance separating the primary from the secondary winding, thus demanding a large component of current at full load which absorbs no power, but simply produces a useless magnetic field.

To calculate the value of this leakage field accurately is practically impossible; but approximations can be made to give results near enough for the fairly close determination of transformer dimensions. The simplest result is obtained by considering the primary coil together with the secondary ring as being removed from the vicinity of the iron core and as equivalent to two parallel and concentric cylinders carrying current flowing in opposite directions; for which case Clerk-Maxwell has mathematically determined the value for the inductance L as

$$L = l\left(4 \ln \frac{d}{a} - 1\right)$$

where L is the inductance of the field,
l is the length of the cylinder in centimeters,
d is the distance between the cylinders,
a is the radius of a circle equivalent to the cross-section of the conductors.

In the case in point, l is the average circumference of primary and secondary, and is therefore $\frac{1}{2}\pi(50 + 22)$ or 112.5 inches, which equals 286 cm.; d is 14 inches and a is assumed to be 4 inches. Therefore

$$L = 286\left(4 \ln \frac{14}{4} + 1\right) = 1720$$

It will readily be seen, however, that the presence of the laminated core reduces the magnetic resistance of the primary leakage path by about one-third, and thus increasing the above value 10 per cent, giving L as 1892.

The value L was also determined by the more accurate but somewhat laborious method of determining the main leakage paths for both coils, the summation for unit current giving the leakage induction per turn.

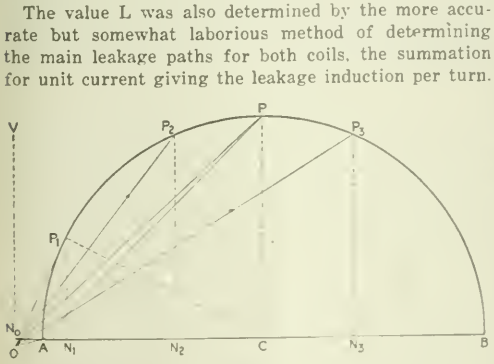

FIG. 1

In this procedure the dividing line of equal magnetic potential for primary and secondary is first calculated; then the mean length of path is determined for a small area, the flux through which can thus be obtained. The same process was repeated for all other sections. The value thus obtained for L was 1870, but since in any such summation the value cannot be too high, certain unobserved paths being left out, L = 1900 is taken as the most likely value. To bring L to henries, or practical units, the result has to be multiplied by 10^{-9}, thus the reactance is $2\pi \times 12.5 \times 1900 \times 10^{-9}$ which equals 0.00015 ohms. (12.5 is the number of cycles in the current to be supplied to the furnace.) This value happens to be exactly the same as the ohmic resistance, so that the tangent of the angle of lag between the resultant current and the applied voltage is unity, the angle is 45 degrees, and the power factor is cosine 45 deg. or 0.707. The magnetizing component of applied voltage with 28,300 amp. as before is 4.24 volts, and the resultant is $4.24\sqrt{2}$, or 6 volts.

In order to obtain the power factor of the primary circuit it is necessary to determine the magnetizing and power component of the open circuit current required by the laminated core. For this purpose a value of 6.3 volts per turn of primary winding is taken—5 per cent increase over the 6 volts computed above being allowed for overcoming the resistance of and forcing the magnetizing current through the primary coil. The magnetic flux passing round the rectangular core, and common to both primary and secondary coils, is given by the relation

$$\varphi = \frac{e \times 10^8}{4.44 \times f}$$

where φ is the magnetic flux,
e is the volts per turn in the primary winding,
f is the cycles of the current;

in our case,

$$\varphi = \frac{6.3 \times 10^8}{4.44 \times 12.5} = 11{,}300{,}000 \text{ lines}$$

on the usual assumption of a sine-shaped wave.

Open Circuit Current

The following tabulation shows the method of arriving at the open circuit current for a magnetic flux of 11,300,000 lines in the core:

Part of Core	Cross-Section, Sq. Cm.	Magnetic Density	Ampere-Turns, per Cm	Length of ϕ Path, Cm.	Ampere-Turns
Limb, inner	950	11,800	6.6	80	528
Limb, outer	950	11,800	6.6	80	528
Yoke, upper	1150	9,800	4.0	135	540
Yoke, lower	920	12,300	8.0	130	1040
Four joints	980	11,500	9200.0	0.1	920
Total					3556

Since the above magnetic density is the peak value, the ampere-turns are also the maximum. Assuming the current to be a sine wave, the peak is $\sqrt{2}$ times the effective value, and the latter is given by dividing 3556 by $\sqrt{2}$. Thus 2500 amp. is the magnetizing current if there were only one turn on the primary coil.

The loss due to hysteresis and eddy currents in the core, assuming the steel to be of good transformer quality, should not exceed 5 kw. at the magnetic density

and frequency stated above. The power component of open circuit current is thus $\frac{5000}{6.3}$, or 800 amp., and the total open circuit current is $\sqrt{(2500)^2+(800)^2}$ which equals 2620 amp.

The current on absolute short circuit with 6.3 applied volts (neglecting primary resistance) is $\frac{6.3}{0.00015}$, or 42,000 amp., the power factor being, of course, zero.

Other values for the relation of current to power factor may be obtained by calculation on varying the furnace resistance and assuming the inductance to be a constant. The latter assumption is very nearly true. Thus, when the furnace is one-quarter full of metal, the equivalent radius for the secondary is one-half that originally assumed. The mean value of a for the combination is then $\sqrt{\frac{16+4}{2}}$, or 3.16. Using this value in the formula instead of 4 gives L = 1820, instead of 1720 for full channel.

Instead of calculating all individual values of the power factor, it is very convenient and sufficiently accurate, with such a very leaky transformer, to use the circle diagram of the equivalent induction motor. This is shown in Fig. 8. In this diagram N_0A is the magnetizing component and N_0O is the power component, drawn to scale and to proper phase; therefore, OA represents the open circuit current to scale. The value of the absolute short circuit current is OB and the semicircle APB on AB gives the locus of the current in value and phase for any chosen voltage. Thus, for a secondary current represented by AP_2 the primary current is OP_2 $\frac{}{n}$ (where n is the number of turns in the primary winding); further, P_2N_2 represents the power component of the furnace current, and $P_2N_2 + N_0O$ divided by the length OP_2 gives the value of the primary power factor; that is, the power factor equals the cosine of the angle OP_2N_2 or the equal angle P_2OV. The highest power factor is at the point where this angle is a minimum: obviously given at point P_1 where OP_1 is a tangent to the circle. In our particular case, OP_1 is almost exactly 10,000 amp., and the power factor reaches 0.91.

Power Factor

The maximum true power consumed in the secondary is given at point P vertically above the center of the circle. This being equal to the radius, its value is ½ (42,000 — 2,500), or 19,750 amp. This value when multiplied by the applied voltage 6.3 gives 124 kw. The furnace current represented by AP is then $19{,}750 \times \sqrt{2}$, or practically 28,000 amp.; the corresponding primary current OP is 30,300 amp., and the primary power factor is $\frac{19{,}750 + 800}{30{,}300}$, or 0.675.

It will be clear from the diagram that any attempt to overload the furnace by adding metal, thus reducing the resistance of the secondary and increasing the primary current beyond about 30,000 amp. would result in less heat being obtained, although the generating plant would get hotter, owing to its giving a higher volt-ampere output. The two points P_1 and P_2 are chosen to illustrate this important feature. In both positions, the true power absorbed by the furnace is 113 kw., but, while this is obtained at P_2 with 23,500 amp. at 0.8 power factor, the same absorption at P_1 requires 35,500 amp. at only 0.53 power factor.

There can never be any advantage in working the furnace outside the limits defined by the first quadrant; in fact, it can seldom be economical to push the current even to within 10 per cent of the maximum power value when the loss and the heating of the generators are considered. When the input current is but 27,000 amp., the power available for heating is still 121 kw., or only 2.5 per cent from the maximum, but the power factor reaches 0.74. The exciting current required by the generators in this case would be considerably less than when giving 30,000 amp. at 0.68 power factor.

Pinch Effect

One consideration which forms a limit to the minimum amount of metal left after each cast is the pinch effect, which is due to the attractive force existing between parallel conductors carrying like currents. The secondary conductor, being fluid, is liable to be broken by such pressure. In the event of the cross-section not being absolutely uniform all around, the break occurs at the place of least cross-section, where the current density is greatest. This phenomenon has been investigated by Dr. Hering, who gives for an open rectangular channel, whose depth is twice its width, the critical current density as 895 $\sqrt{\frac{G}{H}}$ in amperes per square inch, G being the specific gravity of the molten metal, and H the depth of channel in inches. For example, in a channel 8 in. by 4 in. and G = 7, the critical current density is 835 amp. per sq. in. of original section, or a total of 26,800 amp.

Besides this internal stress there is a bodily force acting on the molten conductor, due to the repulsive effect from the unlike current of the primary. The magnitude of this force, with 30,000 amp. in conductors 14 in. apart, is 2.83 lb. per in. of circumference. With a full channel of 72-sq.-in. section, the same pressure would be produced if the molten metal revolved at a speed of about 14 revolutions per minute. The elevation of the outer edge when the metal is very fluid has no doubt given rise to the mistaken idea that the metal revolves bodily.

Primary Coil

The choice of a suitable primary winding was determined by the best output obtainable from the generators, and limited by the size of conductor available, which consisted of a finely stranded rectangular strip, having a net area of about 0.24 sq. in. With two conductors in parallel, a current of 600 amp. could be carried without undue heating, provided a moderate air circulation was available. The coil was wound, therefore, with 56 turns, a tap coming out at 45 turns connected to three terminals, so that changing from full coil to tap, or the reverse, could be carried out without loss of time. When working on full coil and a furnace

current of 28,000 amp., which corresponds to 30,300 amp. through a single-turn primary, the primary winding requires $\frac{30,300}{56}$ or 540 amp. at $6.3 \times 56 = 353$ volts.

If working on the tap, 670 amp. at 284 volts are necessary; some scope is thus provided for working the generators to the best advantage. The resistance of the coil at 200 deg. C. is 0.006 ohms; the loss at 540-amp. input is thus 1750 watts. The electrical efficiency, including 5000 watts core loss, is equal to the true power consumption in the secondary divided by the same figure increased by the core and ohmic losses in the primary. This amounts to $\frac{124}{124 + 1.75 + 5.0} = 95\%$ at maximum power. This is much higher than would be obtained with an induction motor for a similar output.

Pre-heating of Scrap

It has already been mentioned that normally the scrap steel is raised to a red heat in a coal-fired furnace before being fed into the electric furnace, and it will be obvious that where coal is reasonably cheap it must pay to pre-heat as much as possible and thus increase the output for a given supply of electricity. The limit to such pre-heating is fixed by the excessive oxidation of the steel at high temperature when exposed to direct action of the heated gases in the reverberatory furnace, although this may be prevented to a great extent by keeping a smoky or reducing flame over the metal.

It is given in textbooks that about 360 kw. hours of energy can heat and melt one ton (2000 lb.) of steel at about 1450 deg. C. if it could be applied without loss. The specific heat of cold steel is about 0.115, and it is usually assumed that it increases 1 per cent per 10 deg. C. at 1600 deg. C. it would, therefore, be about 0.3, so if the metal is heated, say, 200 deg. above its melting point, the added energy is 64 kw. hours per ton. If the metal is put into the furnace at, say, 480 deg. C. instead of at 30 deg., the average specific heat being 0.115×1.24 or 0.14, the energy saved is 65 kw. hours per ton, amounting to fully 15 per cent of the above 424 units.

It has been found in operation that a supply of 25 kw. to the furnace, in addition to the 5 kw. taken by the transformer, is sufficient to provide all loss by radiation and conduction with a furnace temperature of about 1600 deg. C.; but in actual working, owing to charging and testing, the energy required amounts to about 670 units per ton when casting about 2200 lb. every eight hours; being reduced to about 600 units when casting the same quantity of metal every six hours.

During August the energy supplied to the furnace was 58,656 kw. hours; there was produced 68.6 tons of net castings, the estimated metal melted being 76.3 tons, showing 770 units per ton melted. This energy included the amount required to dry and prepare three new furnace linings.

Frequency Converter

The current conversion is effected by a motor with a generator on each side directly coupled to give the required single-phase current, the armatures being connected in series. The only available generators were "inductor" alternators of a rather out-of-date type, and were converted from 25-cycle into 12.5-cycle machines by altering from six to three poles per side. When giving an output of 600 amp. at 320 volts, with a power factor of 0.68, the true power is 130 kw., the armature drop 14 volts, and the exciting energy for both generators 60 amp. at 75 volts. The output desired from the motor was 220 b.hp., this being required when the generators are giving 130 kw. with an estimated efficiency of 80 per cent; unfortunately, the only motor that could be obtained was one that had originally been built to give 820 b.hp., so that if used as it stood the efficiency would be poor and the power factor very low when working at about 220 hp. Fortunately, it was not very difficult to alter the stator winding from a rather inefficient parallel winding to one in which these windings were connected in two series. Although the motor must work with little rise in temperature, its efficiency is now probably 4 per cent lower than would be obtained with a motor designed to give, say, 250 hp.

Operating Tests

The following readings are taken from the running log. The actual value of the power factor at any particular load could only be obtained by using a power factor meter; but, instead, the volts, amperes and wattmeters are ready every half hour, which gives in practice sufficiently accurate results:

Full Primary Winding (56 Turns)			Primary on Tap, (45 Turns)		
Voltmeter	Ammeter	Wattmeter	Voltmeter	Ammeter	Wattmeter
296	300	240	310	402	18
316	312	282	300	392	66
316	320	318	296	418	120
312	322	360	290	438	168
306	318	408	275	470	222
310	319	450	275	480	276
			265	498	330
Av. 310	315		258	516	378
Kva., 97.65			250	540	432
Kw., 84			253	555	480
Power factor, 86%					

In the second case, the watt reading shows a nearly constant difference, so the average kw. is 103. Considering this to be constant, which it appears very nearly to have been, the average kv.-a. over each hour is 120 at 400 amp., 124 at 438 amp., 131 at 483 amp., 134 at 516 amp., and for the last half-hour 138 at 549 amp., the corresponding values of the power factor are 0.86, 0.83, 0.79, 0.77, 0.75; the latter is the value for the equivalent of $549 \times 45 = 24,700$ amp. in primary for a single turn winding.

During the month of January, 1917, the furnace meter registered 44,940 electrical units, while the meter at the transformer substation showed 71,800, giving an overall efficiency of 62.6 per cent. For August, the furnace received 58,656 units, and the substation meter registered 89,700, giving on the greater average output an efficiency of 65.5 per cent.

Operating Costs

Working costs are somewhat high on account of the small scale of the operations, labor in particular being a very big item. In fact, the same number of hands could probably turn out two or three times the present output with a larger furnace. Three eight-hour shifts are worked, and each of these requires an electrician in charge of the electrical plant and a furnaceman or molder in charge of the furnace. For this latter it has

been difficult to secure suitable white workmen, and colored labor is employed, therefore, on some shifts under supervision of the electrician. Consequently, the number of white furnacemen on the pay roll varies between one and three. The actual furnace charging is done by "Cape boys," of whom five or six are employed in all, and about fifteen natives are used in breaking up scrap and miscellaneous labor. All are under the charge of a works manager, so that the wages bill and supervision fees amount to about £400 ($1940) per month. Electric power is the next big item, and amounts to close on £200 ($970) per month, and the cost of scrap at £1 ($4.85) per ton is third in order of magnitude.

The largest output so far was obtained in July, 1917, when 73 tons of castings were produced at a works cost of less than £14 ($67.90) per ton. In August nearly 69 tons were made, so it is quite safe to assume an average output of 60 tons per month. For this the costs would be approximately as follows:

Scrap, 70 tons, @ £1	£70	$339.50
Pig iron, 1½ tons, @ £20	30	145.50
Aluminum, 30 lb., @ 2/-	3	14.55
Magnesite (calcined), 2 tons, @ £18	36	174.60
Miscellaneous stores	15	72.75
Repairs and renewals	5	24.25
Tools, etc	200	970.00
Electric power	30	145.50
Cartage	20	97.00
Miscellaneous sundries	400	1940.00
Salaries, wages, and supervision fees	£824	$3996.40
Per ton nearly	14	66.50

Economic Considerations

In concluding this account it may not be out of place to call attention to the exceptional opportunity offered by present conditions and prices to make a serious commencement with the iron and steel industry.

Apart from the plant described, small as it is, there are only two other concerns turning out such steel in any quantity. Both work only on scrap, and only one of these has melting furnaces, the other merely reheating and rolling. Both together are quite inadequate to supply the local demand if importation from oversea became impossible. Further, the supply of suitable scrap though large is not unlimited, and in some directions there is an actual shortage of raw material already. So in this direction also the country is likely to be thrown on its own resources before long.

From the point of view of the various iron foundries also, the position is much more serious and must give rise to careful consideration of the possibility of local production. Pig iron of first quality at present approximates in price to £25 ($121.25) per ton, while the prewar price was about £9 ($43.65). At first sight even the latter figure seems attractive enough to encourage local production, but it must be remembered that the whole South African consumption—as pig—is comparatively small and a large output would only be disposable in the form of steel. Even as cast iron, however, the present requirement is enormously greater than before the war; much casting work is being done for the mines and other consumers which formerly was imported, and if only the iron were available at reasonable price, a large industry could be created in the manufacture of pipes and other agricultural machinery. But a very much greater tonnage could be absorbed in the form of steel, and without attempting to cater to all the large and varied requirements now imported, comparatively simple products could be made.

Synopsis of Recent Metallurgical and Chemical Literature

Potash from Blast Furnace Gas.—Two papers read before the Cleveland Institution of Engineers (England) and published in *The Iron and Coal Trades Review*, Jan. 18, 1918, deal especially with cleaning blast furnace gas and the recovery of potash. The first paper, by A. Lennox Leigh, described an installation of a gas-cleaning plant at the North Lincolnshire Iron Company's works. Savings were effected on boilers and stoves by the use of cleaned gas. The author states that so far as a general statement for all furnace plants can be made of the consumption of gas under different conditions, the cleaning of all the gas and its use for boilers and stoves shows a better result than cleaning a portion and using this in the blowing and power gas engines required for the furnace, when taking into account the other economies, the increased value of the cleaned gas and the extra capital outlay for a gas-engine installation. To indicate this the following approximate gas distribution can be compared; it will be noted in the figures given, the reduction of the amount of cleaned gas used for boilers is taken as 25 per cent, not 50 per cent; the reason for this is because the evaporation with uncleaned gas in the plant mentioned is probably lower than in most districts, and an attempt is made to give as general a comparison as possible; any of the figures may have to be decreased or increased for particular circumstances, but to make the comparison of more value it ought to be as near as is possible with average conditions:—(1) Uncleaned gas with boilers and steam engines; (2) cleaned gas with boilers and steam engines; (3) part of gas cleaned for the blowing and power gas engines required for the furnace; (4) cleaned gas with blowing and power gas engines.

	1 Per Cent	2 Per Cent	3 Per Cent	4 Per Cent
Stoves	40	30	40	30
Blowing and power	40	30	15	15
Loss	10	10	10	10
Total required	90	70	65	55
Uncleaned spare gas	10	..	35	..
Cleaned spare gas	..	30	..	45
	100	100	100	100

The author's summary of advantages is as follows:

(1) Economy in gas for boilers.

(2) Economy in gas for stoves.

(3) Fewer stoves required and probably fewer boilers.

(4) Better control of furnace operations and saving in cleaning stoves, boiler flues, etc.

(5) Additional source of income from the larger volume of spare gas of an increased value for the production of cheap power and coal economy.

(6) Recovery of potash as a by-product.

The second paper, by Kenneth M. Chance, dealt with the commercial aspects of the situation. He said with the present rate of pig iron production in England it may be safely estimated that not less than 200,000 tons of potash are being fed into the blast furnaces each year. Of this, in round figures, three-quarters (or 150,000 tons) passes through the furnaces and away in the slags in insoluble form, and one-quarter

(or 50,000 tons) is volatilized and carried from the furnaces in the gas in the form of carbonate, chloride or cyanide, usually a mixture of all three. Of this 50,000 tons, a small proportion is carried down into the dust catchers and down-comers with the heavy dust, and another small proportion is recovered from the stoves and boiler flues, after the combustion of the gas, in the form of sulphate of potash, into which it has been converted during the process of combustion. The remainder, which may be estimated as being in the neighborhood of four-fifths of this 50,000 tons, escapes with the gas up the chimneys and is liberated into the atmosphere. Of all the potash charged into the furnaces, therefore, at the present time, not more than 5 per cent is recovered, and of that 5 per cent quite a considerable proportion is thrown away with the heavy dust as having no value. The British Cyanides Company, Ltd., and the North Lincolnshire Iron Company have carried out a long series of experiments on a practical scale and have devised two methods of recovery. One process aimed to volatize the potash from the furnace, as carbonate is not recommended as a commercial method. A simpler and more economical method of recovering the potash charged into a furnace manufacturing ordinary pig-iron is by adding to the charge an alkaline chloride, of which common salt is the one most readily available. This has the effect of converting the silicates of potash into chlorides, which are volatilized at ordinary working temperatures into the gas in that form, substituting soda for potash in the slags, and there is ample evidence to show that, generally speaking, this method can be relied upon to render available for recovery from 70 per cent to 80 per cent of the potash charged into the furnace in contrast to the bare 5 per cent now recovered.

The author stated that a company has been formed entitled the British Potash Company, Ltd., the shareholders in which are the two firms mentioned, John Lysacht, Ltd., and the government. In the constitution of this company particular attention has been paid to the importance of insuring that its financial strength shall be sufficient to establish a national potash industry capable of holding its own against external competition, and, until this has been secured, dividends upon the share capital are limited to 6 per cent per annum. The whole of the knowledge and experience gained by these firms, together with their inventions relating to the recovery of potash, have been placed at the disposal of the potash company in consideration of the right to subscribe at par for half the shares in that company, and no firm or individual has either asked or received any other consideration of any sort or kind whatever for money expended or services rendered up to the formation of this company. The remaining half of the shares have been taken at par by the government. The shares owned by the private interests, after provision has been made for ample reserves, are to receive by way of dividend out of profits a certain fixed sum per ton of potash produced each year, and the balance of the profits made by the company will be distributed as dividend on the government shares. The proposition which the company lays before the potential suppliers of raw material is that, subject to such arrangements as to detail as will insure the raw material being supplied in such a form that the potash can be economically recovered from it, their raw material shall be purchased by the potash company at a price which will insure them an immediate profit per ton of potash contained in it which is identical to the profit per ton payable by way of dividend on the shares in the potash company subscribed by the private interests. These dividends on the privately owned shares can only be paid out of profits earned subsequent to the establishment of these large reserves, whereas the profit to the suppliers of the raw material is part of the purchase price of that material. That sum in the case of chloride of potash is 25s. per ton, and is equivalent to a potential profit of from 4½d. to 9d. per ton of pig iron.

This is a figure of profit on a by-product of the manufacture of pig-iron and not the purchase price of that by-product, but it is obvious that no company can guarantee a profit on the raw material which it purchases unless it can make a profit on the finished commodity that it has to sell, and therefore, just as in the case of the potash company, this profit of 25s. per ton to the privately owned shares varies upwards and downwards to a certain extent as the cost of production decreases and increases, so arrangements will have to be made with those who supply the raw material that there shall be variation upwards and downwards of this figure of 25s. per ton according to the effect which the form in which this raw material is produced has upon the cost of manufacture of the finished product. Under this arrangement, the state is in a position to insure that the most rigid economy in manufacturing is inforced, and, as their success will depend entirely upon their obtaining ample supplies of suitable raw material at low prices, the potash company will be bound to train and maintain a staff of skilled engineers and research chemists whose duty it will be to assist the suppliers of the raw material to produce the maximum quantity at the minimum cost and to keep their plants running at the greatest possible efficiency. As also the cost of transit from the source of supply to the central factories will be a large item in the cost of manufacture, the potash company will erect a central factory in each district which will undertake to supply sufficient raw material to keep that factory in full operation. After careful consideration it has been determined that the smallest unit consistent with economy is a factory whose output will be not less than 25,000 tons of chloride of potash per annum. The first of these factories has been erected at Oldbury, and is in a position to commence manufacturing operations, and it is the hope and belief of those whom, as managing director of the potash company the author represents, that the company shall be compelled to erect three or four similar factories in other districts, the most important of which is obviously Cleveland. The development of this industry will be watched with interest

Pyrometry

Calibration of Optical Pyrometers.—Wien's distribution law has been universally used in the interpretation and extrapolation of experimental results in the calibration of optical pyrometers such as the Le Chatelier, Wanner, Morse, Holborn and Kurlbaum pyrometers, or the Shore pyroscope which measure temperature by measuring the intensity of radiation of a definite wave

length emitted from a theoretical black body. This law is stated as follows:

$$\circ(\lambda, \theta) = \frac{Ce^{-\frac{c}{\lambda\theta}}}{\theta^5}$$

where $\circ(\lambda, \theta)\ d\lambda$ is the intensity of radiation of a black body at absolute temperature θ produced by waves of length between λ and $\lambda + \delta\lambda$ and C and c are constants. F. E. Wood criticizes this formulation in the *Philosophical Magazine*. Vol. 35, page 190 (Feb. 1918, from a mathematical point of view, and shows it to be inconsistent with other results following from Wien's assumptions. He derives a new law, which is shown to be consistent with correlated formulae as follows (notation as before):

$$\circ(\lambda, \theta) = \frac{Ce^{-\frac{c}{\lambda\theta}}}{\lambda^5}$$

Iron and Steel

Metallurgical Treatment of High Speed Steel—J. L. Thorne recently presented a paper before the Steel Treating Research Society in Detroit, giving considerable information on this subject. He warns the purchaser from buying steels by trade name only, since there have been instances where the composition has been materially changed without notice to the user. The high speed steels on the market now are comprised within the following limits, a third column giving a good chemical specification.

	Range	Proposed
Carbon	0.47 to 0.91%	0.65%
Silicon	0.12 to 5.00	0.12
Manganese	0.12 to 0.67	0.25
Sulphur	0.008 to 0.057	0.02
Phosphorus	0.006 to 0.051	0.02
Chromium	1.50 to 5.52	3.5
Vanadium	0.13 to 2.5	1.0
Tungsten	11.74 to 22.27	18.0

As the steel is purchased it is sampled and analysed. Close adherence to chemical specification is impossible and undesirable. Sulphur and phosphorus should be kept low; manganese as low as necessary to inspire against harmful sulphur effects, and silicon low to prevent brittle silicide segregations. The tungsten-chromium-carbon combination is of course responsible for the "red-hardness"; while vanadium, originally added merely as a scavenger, increases the elastic limit and the resistance to wear and shock. New high-speed stock should have a hardness slightly under Brinell 250 or scleroscope 35 in order that it may be machined readily. Microscopic examination is also undertaken before the material is accepted, looking particularly for forging cracks, surface decarbonization, uniform structure, segregation and ingotism.

After the tool has been formed and sent to the hardening room, it should first be given a "soaking" heat at from 1500 to 1800 deg. F. to avoid expansion strains and cracks if suddenly put into the high hardening heat. When uniformly heated, it is transferred to a high-temperature furnace, whose heat is as uniform as possible, controlled with standardized pyrometers, and allowed to remain there a certain specified time. This time is automatically registered by colored lights and warning buzzers, so that at the proper instant the tool can be removed and quenched—preferably in oil, circulated over cooling coils to maintain a uniformly low temperature. Taylor discovered that to get the maximum red-hardness this quenching temperature must be far above the critical temperature—approaching that where the tool actually softens. This hardened tool is then "drawn" in a low temperature furnace—bearing in mind that the metal progressively softens up to a point lying between 700 and 800 deg. Fahr., from which to about 1100 deg. it increases in hardness with the temperature.

In a very extensive test of nearly a thousand drills made of all available domestic and foreign high-speed steels, it was discovered that the most efficient tools exhibited a great resemblance in microscopic structure, regardless of their manufacture or heat treatment. This has led to the adoption of the so-called "standard structure" to be looked for in experimenting to discover the proper heat treatment to give a new lot of metal. Start with several samples and subject them to various temperatures for various times approximating the expected conditions; a microscopic examination will then show that one which nearest approached the standard structure. As the temperature and time of this piece is known, proceed to another set treated at temperatures and times slightly above and below the first approximation. In this way, the third series will give the exact heat treatment which will produce the desired structure. Finished tools are then run on an experimental drill press, and their work compared to that done by one of a set of control tools, and reported as so much plus or minus standard.

Malleable Cast Iron.—In a discussion of the necessary characteristics of successful production of "white-heart" castings, Mr. E. Adamson, in a paper read before the Staffordshire Iron and Steel Institute, Jan. 12, 1918, presented an interesting tabulation of the role played by the chemical composition, reproduced below:

	Si	S	Mn	Total Carbon
Separation of graphite or free carbon is *induced* at a temperature which is lower	the higher the Si	the lower the S	the lower the Mn	the higher the total carbon
The rate of separation of graphitic carbon is less the lower the temperature and	the lower the Si	the higher the S	the higher the Mn	the lower the total carbon
Combined carbon corresponding to equilibrium at a given temperature dimishes with	increasing Si	lower S	lower Mn	higher total carbon

The author remarks that it is important to note that the separation of graphitic carbon once induced will continue at lower temperatures and that graphitic carbon begins to form in the molten iron. Hot metal, for a white iron casting, must therefore be retained in the ladle a minimum time, and annealed carefully to prevent rapid precipitation of free carbon.

The facts noted in the column headed silicon were published in 1902 by Charpy and Grenet, and are understood well enough to require no further comment. The total carbon rarely amounts to less than 3 per cent; 2.75 per cent is hard to anneal, but will be harder and stronger after a longer annealing at higher temperature. While it is possible to get good "white-heart" castings with sulphur as high as 0.25 per cent, the margin of safety in annealing is much greater if sulphur is much lower, say, 0.05 per cent. A high sulphur, under-annealed casting is brittle, over annealed it will exfoliate. Manganese is not capable of masking the ill effects of sulphur, oft-repeated statements to the contrary. Phosphorus is quite safe up to 0.25 per cent.

Recent Metallurgical and Chemical Patents

Production of Metallic Nitrogen Compounds.—MATHIAS SEM, of Christiania, Norway, proposes to produce cyanamids by introducing a carbide in the form of dust, together with nitrogen into a reaction chamber. The nitrogen as well as the carbide should be preheated to about 700-800 deg. C., and before the process is started the brickwork of the furnace is also heated up. The exothermic character of the process is utilized to maintain the necessary temperature in the furnace and partly to bring about a very rapid nitrification. (1,256,935, Feb. 19, 1918).

Cyanides and Ammonia.—PAUL A. STARKE of Berkeley, Cal., patents the production of cyanides from natural gas and ammonia in the presence of a catalyzer of sodium carbonate, magnesium oxide and iron. The gases are passed through the reactive substance in a retort heated to 1,000 deg. C. The cyanides formed are recovered by lixiviation and crystalization. (1,256,272, Feb. 12. 1918). In another patent the same process is used to produce ammonia from natural gas and air. In this case a high pressure is used and a temperature of from 400 to 800 deg. C. The ammonia is absorbed as sulphate or liquefied. (1,256,273, Feb. 12, 1918).

Miscellaneous Chemical Process and Products

Sulphuric Acid and Salt Cake from Niter Cake.—A method of decomposing niter cake incidental to sulphuric acid manufacture is patented by LAURENCE T. SHERWOOD, of Connellsville, Pa. By this process the heat of combustion of the sulphur or pyrites is utilized by a simple apparatus for the decomposition of the niter cake and the decomposition of the niter cake furnishes sulphur-oxides which are used along with the sulphur-oxides of combustion in the manufacture of sulphuric acid; thus an economy of fuel is affected. (1,255,474, Feb. 5, 1918).

Electrical Insulating Compound.—WILLIAM T. CUSHING of Milwaukee, Wis., patents an electrical insulating compound, the patent being assigned to the Cutler-Hammer Mfg. Co., of Milwaukee. The composition comprises asbestos and a binder including a varnish of East India gum, China wood oil and rosin and an oxidation retarder of stearin pitch and coal tar pitch in the proportion of approximately two parts of the former to one part of the latter. (1,255,139, Feb. 5, 1918).

Purifying Barium Sulphide.—W. E. PRISK and H. R. HARRISON of Halifax, Nova Scotia, patent a method of purifying barium sulphide by arranging the apparatus so that the solution is passed alternately through a plurality of filters, containing manganese dioxide and calcium carbonate, alternately, the solution being subject to the action first of one of these materials, and then of the other, and the process being continued until all of the impurities are removed. After the solution is thus purified, it may be used for the preparation of insoluble salts of barium, such as barium sulphate, and these salts may be used commercially as desired. (1,256,593, Feb. 19, 1918).

Manufacture of Ammonium Nitrate.—REIDAR BLOM, of Rjukan, Norway, describes a process of making highly concentrated solution of ammonium nitrate or even this salt in the solid state directly by means of the dilute acid. The process is based upon the observation that solutions of ammonium nitrate are excellent absorbents for ammonia gas. Therefore the dilute solutions of ammonium nitrate obtained by neutralizing ammonia water with dilute nitric acid or in any other way may be used for absorption of ammonia gas, and the ammoniacal solution so obtained is neutralized with dilute nitric acid. By repeating at will these operations of absorption and neutralization it is possible to obtain saturated solutions of ammonium nitrate or a precipitation of the solid salt respectively the cost of evaporation thus being reduced to quite a minimum or even totally eliminated. (1,256,513, Feb. 19, 1918).

Refractory Material.—HANS M. OLSON, of Lompoc, California, patents a heat-insulating composition consisting of infusorial earth in a finely divided state, and a binder of sodium sulphate, aluminum sulphate and lime, the infusorial earth being from 75 per cent to 95 per cent of the entire mass, and the binder from 5 per cent to 25 per cent. (1,257,922, Feb. 26, 1918).

Hydrocarbon Coke.—R. P. PERRY, of Montclair, N. J., patents a process of coking coal-tar pitch and similar liquid materials by heating the material in liquid form in comparatively thin films on a moving surface. The patent is assigned to the Barrett Co. of New York City. The process is equally applicable to the residue from petroleum refining which is usually coked by continued high heating in the stills, thereby greatly shortening their lasting qualities. The apparatus patented is similar to a film dryer and delivers coke continuously by a hot cylinder rotating in a liquid bath, catching up some of this liquid, coking same and delivering it to a bin during the rotation. (1,257,959, Feb. 26, 1918).

Electrolytic Processes

Electrolysis of Foul Copper Sulphate.—F. L. ANTISELL of Perth Amboy, N. J., utilizes the following equipment for the electrolysis of copper sulphate solutions containing large amounts of such impurities as iron salts: A rectangular tank with cathodes suspended near either side, the tank itself having filling and drain pipes. Supported within the tank and between the cathodes is a smaller rectangular container containing granular gas-house carbon, and provided with independent filling and drain pipes. The sides of the container may be of rotary cut wood veneer, in case the container is to act as a diaphragm; otherwise it may be latticed or consist of wire netting. The granular carbon acts as the anode, being energized by carbon rods immersed in the container.

Using the wood diaphragm, a good deposition of copper may be had from solutions containing as low as ½ per cent copper, and at the same time increase the acid content of the solution by the use of H_2SO_4 as a depolarizer and circulating same through the anode. The cathalyte is also circulated. The voltage is reduced for several reasons. One is that the numerous points of the crushed carbon present areas of low-surface tension as well as a greatly increased surface of collection where the oxygen is easily liberated, thus reducing the

resistance between terminals. The veneer separates the anolyte from the catholyte sufficiently so that any ferrous iron in the solution will act as a depolarizer, and ferric iron cannot migrate to the cathode with correspondent reduction of current efficiency.

In case a perforated container is used, the solution to be electrolyzed is entered through the crushed carbon and drained from the outer tank. This permits a very high anodic efficiency, which is often as low as 5 or 6 per cent when depolarizing with SO_2 gas, but which attains 80 per cent in this method, with consequent decrease in voltage. The voltage of a tank using an insoluble lead anode after being in service a short time is about 1.20 volts at the anode. In addition to this is an ohmic resistance of about ½ volt (when operating at a current density of 16 amp. per sq. ft.), due to the lead oxide which rapidly forms on the anode. The counter electromotive force of the carbon anode is about 0.35 volt, at which plating begins. At 10 amp. per sq. ft. the voltage increases to 1.30, and the ampere efficiency is maintained at nearly 100 per cent. The power input is, therefore, materially lowered.

In electrolzing leach solutions containing copper and iron, it is usual to continue the electrolysis only as far as the time where the ampere efficiency drops below 80 per cent, when the balance of the copper is precipitated upon iron, at the expense of the iron, sulphuric acid, and large labor cost. With the present cell, it is claimed that solutions containing as high as 50 grams of iron per liter have been successfully electrolized. (1,239,443, Sept. 11, 1917.)

Aurocyanide Electrolysis.—U. C. TAINTON of Johannesburg, Transvaal, proposes to recover gold and silver from cyanide solutions with high base metal or low free cyanide content by the aid of an electrolytic cell illustrated in Fig. 1, having as rotating cathodes 13 a disk of wire mesh, or a thin sheet with serrated arms cut in it designed to pick up and hold metallic threads which may be introduced with the solution. The anodes 19 are of lead, encased in a non-conducting rim and porous diaphragm 22, to prevent the anode products from mixing with the catholyte and causing resolution of the precipitated metal. The anode compartments may also be partly filled with alkaline sulphate solution to prevent disintegration of the metal, and are provided with vent pipes 20 for the escape of gases generated. The rich solution enters the casing through pipe 32, and part of the metal is precipitated in the meshes of the first rotating anode as it passes through. High current density and rapid rotation will cause the incoherent deposit to become detached and carried along with the electrolyte through successive openings in the anode compartments and whirling cathodes until the solution carrying substantially all the values as finely divided metallics is drawn off through pipe 33 and settled or filtered as desired. (1,251,302, Dec. 25, 1917.)

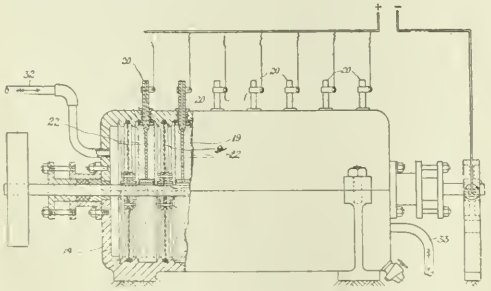

FIG. 1. ELECTROLYTIC CELL FOR CYANIDE SOLUTIONS

Nickel-Copper Separation. — GEORGE A. GUESS of Oakville, Ontario, patents a process of separating nickel from copper by the electrolysis of nickel-copper anodes in an electrolyte of nickel sulphate containing an insoluble reagent, such as alkaline earth carbonate of hydrates, preferably limestone. The reagent is kept out of contact with the cathode by means of a porous diaphragm. As the nickel and copper sulphates form at the anode, the copper sulphate is precipitated on the limestone, forming insoluble copper carbonate and calcium sulphate, while the nickel migrates to the cathode and is plated out of solution. (1,251,511, Jan. 1, 1918.)

Filter-Press Electrolyzer.—H. T. SHRIVER of West Orange, N. J., has patented improvements to the leaves of the ordinary filter-press type electrolyzer, Fig. 2, commonly used in the production of oxygen and hydrogen from water. He casts gas chambers above each plate, into which the liberated gas enters through ports 22, and from which they escape over the top of the partition 21 into continuous ducts 13 or 14, and thence to separate tanks for their reception. In this manner the electrolyte is entirely absent from the gas ducts, preventing the customary short circuiting and loss of efficiency due to this cause, since the pressure on the electrolyte is such as to keep its level continuously below the tops of the partitions 21. The supply of pure water necessary to replace that electrolyzed is introduced through the continuous ducts 29 and 30, from which it enters each section as needed through grooves 31 and 32 cast in the side of the leaves. The water enters the bottom of the section, and diffuses upward through the denser electrolyte, each section being automatically kept at the proper density and elevation by maintaining a proper pressure on the fresh water supply. (1,239,530, Sept. 11, 1917.)

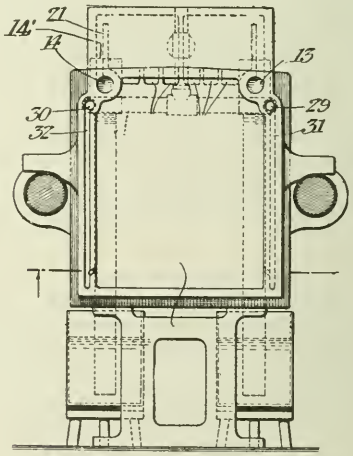

FIG. 2. OXYGEN AND HYDROGEN GENERATOR

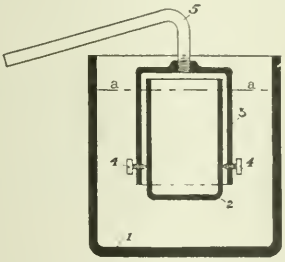
A New Experimental Retort for Dry Distillation

By F. E. Coombs

DURING the course of a long series of dry distillations it became desirable to control the temperature in varying limits, and to have means for easily and quickly opening, cleaning and closing the retort, while still hot. Nothing of this nature being available in stock apparatus the form described in this article was devised and used successfully.

The accompanying illustration shows clearly the construction of the retort and vessel for holding a bath of suitable fused heating means. The original apparatus was put together from ordinary iron pipe and fittings and worked satisfactorily. It is, of course, a better plan to make this outfit from pattern as a casting, for which either iron, brass, aluminium or any other preferred material may be used, according to circumstances.

The drawing shows, 1, an iron vessel to hold melted lead, sulphur or caustic soda, according to the temperature range required. This vessel is conveniently supported and heated and a thermometer dipped into the bath for control of heating.



CROSS SECTION OF RETORT FOR DRY DISTILLATION

A container, 2, with a very loosely fitting cover, 3, is filled with the assay and immersed to a point where the level of the fused bath (a) will be safely below the top of the container; the cover is firmly fixed to the container by means of three screws, 4, so that there is an approximately even space of about ¼ inch between cover and container, serving as a seal-channel, which may be made as deep as the conditions of the work demand. That is to say, if a distillation only is required and the internal pressure is not to be much above the atmosphere, both container and cover may be fairly shallow; but if gases are to be collected, or the vapors forced against material resistance in the way of absorbers, etc., then proportionate depth of seal must be provided in designing the container and cover.

A gooseneck, 5, is screwed into the top of the cover, and in the case of small apparatus this will be used as a handle and is held in the usual ringstand clamp when in use in the bath.

A section of 4-in. pipe 7 in. long will hold about 20 lb. of melted lead and can be brought to and kept in fusion with a large Bunsen burner. A bath of this size will permit a container about 3 in. by 2½ in. to be immersed, cold, without "freezing" the lead if brought well above the melting point.

In tests with substances whose heat-reactions are not definitely known, this form of retort saves breakages of condensers and tubing, for swelling of the assay and stoppage of the gooseneck simply forces exit through the seal. It goes without saying that the retort and all of its parts must be dry when placed in the hot bath, or there will be steam explosion and scattering of lead or hot material. Further, in bringing a solidly filled bath of lead to fusion, melt from the top, to avoid expansion under the solid lead and danger of cracking the container. Or the alternative may be used of running a small diameter wooden or metal rod to the bottom of the bath before setting it aside to solidify, so that a relief channel may be formed from top to bottom to take care of expansion when again fusing.

The retort can be taken apart while practically red hot and there is little temptation to use water on it for cooling. It is accessible for perfect cleaning and the cost is insignificant. As 1 in. of lead is equivalent to about 11 in. of water, a seal of an inch or two is enough for ordinary purposes, including collection of gas over mercury trough, potash bulbs and open scrubbers.

Crown Willamette Paper Co.,
Floriston, Cal.

Measuring Coke Oven Gas Used in Soaking Pits

INCREASING quantities of surplus gas from by-product coke oven plants are being consumed in various processes in steel mills and it is desirable to have an accurate and reliable measurement of this gas. For this purpose the Thomas meter has been applied, which measures the quantity of gas in standard units, such

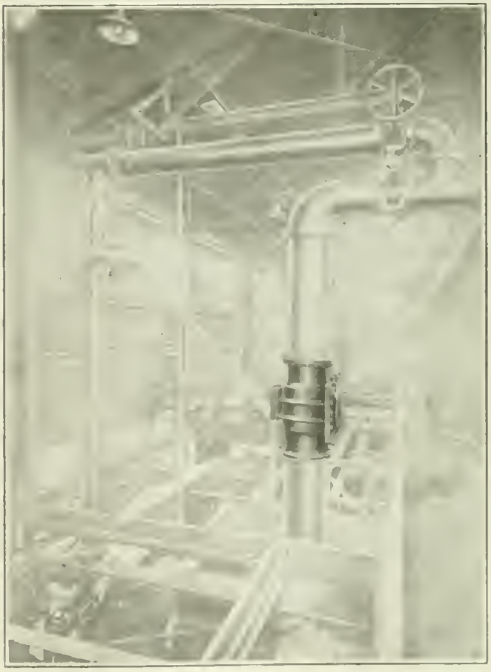


FIG 1. HOUSING INSTALLATION, BRIER HILL STEEL CO.

as cubic feet at 30-60, without any calculations or corrections for pressure and temperature, although these may vary through wide ranges. The total quantities (in cubic feet) are shown on an integrating meter and the rate of flow is shown graphically on a curve drawing instrument. The graphic chart obtained from this instrument is very useful to the superintendent of a coke oven plant, showing him at a glance the amount of gas being used for fuel in the coke ovens over any period, with variations in quantities clearly indicated.

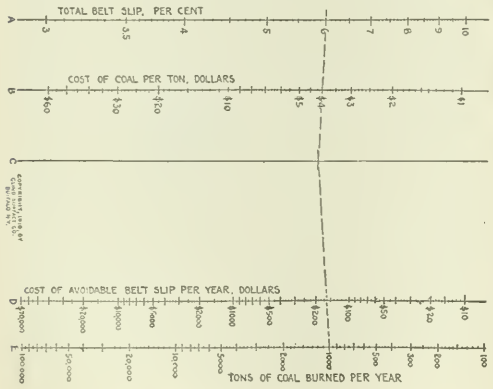
The meter is installed in a housing which replaces a portion of the gas pipe line as shown in the accompanying illustration of an installation at the Brier Hill Steel Company, Youngstown, Ohio. The principle of the Thomas meter is that it measures the heat capacity of a gas electrically. The amount of electric heat necessary to raise a standard unit two degrees is used as a measure of the gas flowing through the meter. The electricity for heating the gas can be conducted on comparatively small wires, consequently the meters showing the amount of gas used can be placed in the superintendent's office or other desired location, which may be several hundred feet from the meter proper.

The graphic chart shows him at a glance just how much gas is being used at any time in the soaking pit building. The complete Thomas meter and recording panels are made and installed by the Cutler-Hammer Manufacturing Company of Milwaukee, Wis.

The Cost in Coal of Avoidable Belt Slip

TO show the extent of the loss of money through slipping of the main belt alone a chart, supplied us through the courtesy of the Cling-Surface Company, Buffalo, N. Y., is shown herewith, upon which this is easily ascertained. By glancing up and down column "D" of this chart it is evident that the "cost of avoidable belt slip per year in dollars" may vary all the way from the smallest sums into the thousands of dollars.

Where the power in the first place is generated by a steam engine and is then transmitted to a generator or to the main shaft through a main belt it is evident that the "entire coal pile" passes through that in the form of energy, literally speaking. If the belt slips, which it should not do, a certain portion of the coal pile does not



TOTAL BELT SLIP, PER CENT
COST OF COAL PER TON, DOLLARS
COST OF AVOIDABLE BELT SLIP PER YEAR, DOLLARS
TONS OF COAL BURNED PER YEAR

FIG. 1. CHART FOR DETERMINING COST OF BELT SLIP

"get through," but is lost into the atmosphere in the form of waste heat. A main belt is merely a "link" connecting the engine with the generator or with the machines themselves. In fact, every belt that transmits power is a connecting link and the efficiency of that link depends largely upon the freedom from slippage and the avoidance of strain on the shafts. Slipless, easy-running belts are most desirable.

To give a clear idea as to the meaning of "total belt slip per cent" take the following example: You find by means of a revolution counter that a given driven pulley is rotating only 940 times per minute. You figure that without slip it should rotate 1000 times per minute. Sixty revolutions per minute, therefore, are absolutely lost. Dividing this 60 by the r.p.m. that pulley should make you get 0.060, or 6 per cent, which is the "total belt slip." After having made this determination it is a simple matter to apply it to the chart and determine the money loss per year due to such slip.

Furthermore, belts which do not slip do not require tension and can be run easy or slack—every belt thus relieved of its tension reduces by that much the total plant friction load and this means also a longer-lived belt, cool bearings, less oil used, less time of men and machines lost during repairs and more power at the machines, for friction represents lost power.

A New End-Suction Centrifugal Pump

A new design of centrifugal pump manufactured by the Wheeler Condenser & Engineering Company, Carteret, N. J., is of special interest because of the unusual position of the suction opening. This opening, it will be noted, is directly beneath and parallel to the end bearing. In this position it is out of the way, yet it is in a convenient place for the erection men, for inspection, for upkeep, etc.

This arrangement makes it possible to place a pumping unit in a room of small ground area—considerably

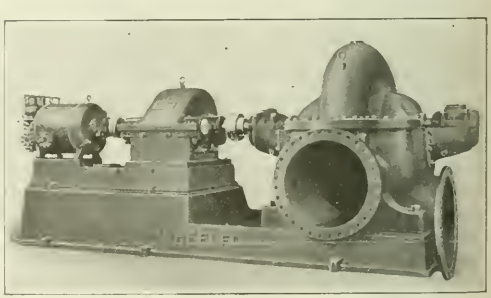


FIG. 1. ASSEMBLED VIEW OF END-SUCTION PUMP

smaller than where the suction end is opposite the outlet end, as is the most common practice. In many cases this also facilitates the making of pipe connections, saving elbows and reducing the length of piping.

The capacity of the particular pump shown is 45,000 gal. per min. against a head of 20 ft. The diameter of the outlet pipe is 36 inches. The speed of the pump is 240 r.p.m. and is coupled by a 10 to 1 reduction gear to a steam turbine, whose speed is 2400 r.p.m.

Personal

Messrs. G. W. AKERLOW and J. M. LUNDQUIST have opened an office as consulting and mechanical engineers in Denver. They will handle mill design, special machinery and oil shale refining plants.

Mr. WATSON BAIN, professor of applied chemistry at the University of Toronto, has been granted leave of absence for the duration of the war. He is going to Washington, D. C., where he will be on the staff of the Canadian mission.

Dr. JOHN E. BUCHER, professor of chemistry in Brown University, has been granted leave of absence for the second semester of the academic year, in order to devote himself to experimentation in chemical processes in the industry. He will continue to direct the work of certain advanced students in the university laboratory, but will be relieved of all teaching during the remainder of the year. Dr. Robert F. Chambers, a Brown graduate, will be acting head of the department during the second semester.

Mr. W. C. CAPRON has been advanced from the position of assistant chief engineer of the Washoe Reduction Works to that of mechanical superintendent of the same plant. A number of other changes in the engineering staff of the Anaconda Copper Mining Company have followed this change. Mr. C. D. WOODWARD has been transferred from assistant chief engineer of the Great Falls reduction department in Butte, where he will be chief electrician of all the Anaconda properties in Montana. Mr. Woodward is succeeded in Great Falls by Mr. GEORGE TYRON, formerly chief draftsman of the Washoe Plant. Mr. H. W. RUTHERFORD, designer, becomes superintendent of construction for Stack, Cottrell Treaters and Arsenic Plant, Washoe Reduction Works, succeeding Mr. W. E. MEALS, who becomes chief draftsman.

Dr. F. E. CARRUTH, formerly connected with the chemical division of the North Carolina Experiment Station, has become associated with the Schaefer Alkaloid Works, Maywood, N. J.

Mr. E. R. CRUTCHER, superintendent of the Judge Smelter, Park City, Utah, has resigned and will go to South America. He is succeeded by J. F. ELLSWORTH.

Mr. A. A. HAWKES has been named to succeed J. M. GOETCHIUS as vice president and director of the General Chemical Co. Mr. GOETCHIUS resigned in order to give his services to the Government.

Mr. HERBERT LONGSTAFF has been appointed St. Louis manager for the Asbestos Protected Metal Co., of Pittsburgh, Pa.

The following changes and additions have recently been made in the sales organization of the Pfadler Co., Rochester, N. Y.: Mr. W. E. FOSTER now represents them as manager of the Atlantic Coast Sales Division; vice, F. L. CRADDOCK, with headquarters at the New York office, 110 West Fortieth Street. Mr. PHILIP S. BARNES, formerly with the Avery Chemical Company, of Lowell, Mass., is now associated with the sales department as consulting chemical engineer, with headquarters at the New York office. On April 1st the Chicago office will be removed from the Schiller Building, where it has been for a number of years, to 1442 Conway Building. Mr. R. B. KILMER is in charge.

Dr. C. L. REESE, of E. I. du Pont de Nemours & Co., has been named chairman of the committee on dyestuffs and intermediates of the Chemical Alliance.

Mr. H. D. SAVAGE, manager of sales, has been elected vice president of the Locomotive Pulverized Fuel Company. He will also continue as vice president of the American Arch Company.

Mr. LEWIS SEARING, of the Denver Engineering Works Co., has sold his half interest in the Denver Engineering Works Co. to the Hardinge Conical Mill Co. Mr. Searing will terminate his connection with the company on June 1.

Dr. WILLIAM P. WOOD, assistant professor of chemical engineering at the University of Michigan, has resigned, to join the Signal Corps of the Army.

Current Market Reports

The Iron and Steel Market

There has been no revival of activity in the pig iron and finished steel markets since the reaffirmation of prices for another three months, to July 1, with slight revisions in pig iron and scrap prices. There was no particular reason to suppose that the market would increase in activity. There is heavy Government buying, heavier perhaps than early in the year, but this is not considered market activity, all such buying being practically in the form of allotments.

As to commercial steel buying, it is to be borne in mind that the steel mills are carrying on their books more than 12,000,000 tons of purely commercial business, entirely apart from war orders, direct from the Government, or indirect. These obligations represent something like normal requirements of regular buyers, chiefly jobbers and manufacturing consumers. These buyers have no occasion to enter into additional engagements, for distant deliveries, as conditions are not such as to enable them to gage their consumptive requirements far in advance. The incentives to forward buying that frequently exist are altogether absent now. There is no definite prospect of there being higher prices in future. There is no particular advantage in buying early to secure a place on order books as deliveries will be regulated by Government requirements and the Government's views as to the usefulness of the buyer's industrial operations. There may be lower prices fixed by the Government, in which case the buyer is protected, but the Government edict in this respect does not cover the buyer against declines in the open market, below the set prices, produced by open competition, and of such competitive selling there is a distinct possibility.

An additional cause for the dullness in the open market is the fact that new projects are lacking. The commercial requirements in steel, such as they are, come from regular buyers, who are already covered, and do not hinge upon new projects.

DELIVERIES MUCH HEAVIER

Transportation conditions have been steadily improving, and a double result follows. Shipments from mills are heavier, and material long delayed *en route* has been reaching the buyer, so that while shipments have increased, deliveries have increased still more. This is beginning to tell upon the situation, and the majority of buyers of finished steel products find themselves in much more comfortable position. It is quite possible that within a few weeks many buyers will request mills to reduce shipments.

Production of finished steel has not increased as much as shipments. At practically all mills in the past few weeks there has been a reduction of stocks accumulated in January and February, and in nearly all cases it is desired to reduce the stocks greatly, as much of the tonnage is sadly in the way, having accumulated by force of circumstances and not by design. Shipments of finished steel during the fore part of April may be estimated at about 90 per cent of capacity, and production at 80 to 85 per cent. Capacity having increased very materially of late, shipments are now at approximately the average rate that obtained in 1916, when the existing capacity was fully employed.

Pig iron production has increased very sharply in the past few weeks, from a rate of 25,000,000 tons a year or thereabouts in the early part of February to a present rate of close to 40,000,000 tons. The greatest production in a calendar year has been 39,400,000 tons, in 1916, while through the completion of 17 new furnaces since 1916 capacity at present is about 43,000,000 tons.

There remains some shortage of coke, but only in spots. Shipments of Connellsville coke have greatly increased and are now approximately equal to the requirements of the furnaces still tributary to the region. These requirements are materially less than formerly, by reason of the com-

pletion of so many by-product ovens, and further decreases are to occur as additional by-product ovens are completed. Since the beginning of 1917 by-product capacity has come in to the extent of about 4,500,000 tons a year, while new plants scheduled for completion within the next few months will add fully 6,500,000 tons more, making an addition of considerably more than 10,000,000 tons since the end of 1916, yet in 1916 there was coke sufficient for the production of 39,400,000 tons of pig iron, and the present blast furnace capacity, as just noted, is only about 43,000,000 tons. While Connellsville coke sold at $10 to $15 a ton before the Government set the price at $6, it is quite possible that coke will eventually seek a market at much below the Government limit.

Prices in Future

The only changes made in prices to rule from April 1 to June 30 were a reduction of $1 a ton in basic iron and reductions of $1 a ton in all descriptions of scrap upon which prices had been fixed. Basic iron dropped from $33 to $32, at furnace, and this brought Bessemer down from $36.30 to $35.20, as Bessemer is set at 10 per cent above basic.

It was made clear by the War Industries Board that the chief reason a general reduction in steel prices was not sought at the conference late in March was that the producers had had a hard time in the winter, with very irregular operations and consequently particularly high costs. The board's idea seemed to be to give the industry three months time without change in prices, and then consider conditions afresh. With the much steadier operations now possible costs are bound to decrease, although it is to be noted that wages were advanced about 10 per cent, effective October 1, just after the original price agreement was reached, and April 15 an additional advance of about 15 per cent becomes effective. Wages will then be very nearly double what they were in 1915, and almost triple what they were in 1898, as a result of five years of industrial depression.

On the one hand there is a distinct possibility of general, though not great, reductions in iron and steel prices July 1, by action of the Government, while on the other hand there are distinct possibilities of market declines through open competition, it being quite clear that all war requirements combined can hardly engage more than one-half the total productive capacity, while the strictly peace demand that remains can hardly be expected to absorb the other half. At the same time the general attitude of producers is that the set Government prices, prescribed as maximum, should in the general interest be regarded as minimum likewise.

For the long future, it is becoming clearer week by week that no return to former costs in the iron and steel industry is to be expected. Labor is on a different basis, and working conditions in the industry must be made such as to attract native born labor. Steel prices after the war may be, and probably will be, lower than at present, but no return to levels obtaining previous to the war can possibly be expected in view of conditions as they have lately been shaping themselves.

Non-Ferrous Metal Market

Monday, April 8—There has been practically no change in the tin situation and copper is moving steadily with demands being fairly well taken care of. The lead situation has eased up considerably and supplies are plentiful. Spelter continues weak.

Copper—Transportation facilities have improved and fewer delays have resulted. Consumers are being well supplied at present and although the demand from the Government and the Allies is expected to be increasingly heavy, the producers are expected to be able to meet them. The price remains at 23.50c. for producers and 24.67½c. for jobbers. Smelter production is estimated at 200,000,000 lb. per month.

Tin—Spot stocks are very low and few supplies are for sale. The market is very difficult and while it is not impossible to pick up small odd lots here and there, they are very scarce and are 99 per cent material. China is about the only source of supply at present and spot is held at around 90 cents with futures at 80 cents.

Lead—Lead is slightly lower and has sold in the New York market for from 7 to 7¼ cents. In E. St. Louis the price has been 6.90 to 7.17½ cents. The large producers are well sold up but supplies have been more freely offered by the small producers.

Spelter—Spelter continues to decline and has dropped to 6.90 to 7.00 cents E. St. Louis and 7¼ cents New York. The lower price will probably further decrease production.

Palladium, oz.	150.00
Cobalt, lb.	3.25-3.50
Magnesium, lb.	2.00
Quicksilver, Cal.	120.00
Quicksilver, Mexican	115.00

Chemical Market

Coal Tar Products: The market was particularly quiet in most of the important items during the interval. Prices were somewhat easier in the crudes, due to the more liberal offerings and the falling off in the demand.

Benzol: The demand is confined mostly to spot material, but there is a fair volume of business passing on contract over short terms. It is said that some large contracts have been closed at a concession.

Toluol: Some large quantities have been released by the governmental authorities of late, for use in intermediates and dyes. The government appears to be determined not to permit offerings on the open market, although there are small quantities available from time to time.

Phenol: Offerings have been considerably augmented and with the demand quiet prices are slightly easier.

Naphthaline: While the demand is not pressing, offerings are light and prices are fairly well maintained.

Aniline Oil: The demand has been quite active of late and though there are resale lots available at a concession in price, producers are quite firm in their ideas.

Beta Naphthol: There has been an active demand for the technical material, but prices have held steady and unchanged, as there are large quantities available.

Benzoate of Soda: The consuming demand has not, as yet, been heavy, and, though there is some fluctuation in price, in general the position is unchanged.

Phthalic Anhydride: Some of the important factors are energetically endeavoring to secure business, and prices have depreciated under the strong competition in the market.

H. Acid: There are large quantities on the market, with the demand more or less routine and prices unchanged.

Resorcin: Considerable competition has developed and with only a moderate demand prevailing prices are easier.

Salicylic Acid: Is weak with the demand light because of inability to secure export licenses.

Sulphanilic Acid: Is not in heavy demand, but there are only a few producers and prices are unchanged.

Benzyl Chloride: There are only a few producers offering at present because of the scarcity of toluol, and prices are inclined higher.

Benzidine Base: Is only fairly active and prices are unchanged with a moderate production.

Heavy Chemicals: The feature of the market during the past two weeks has been the recovery of caustic soda from the low point recorded in our last issue. Material shipped to this point had accumulated to such an extent that pressure was brought on owners with view to releasing cars and as a consequence caustic was offered at concessions. Aside from this movement the market has been quiet and the trade has as a rule been disappointed with the amount of trading that has come to hand.

Caustic Soda: From a price of below 4c., the market has

advanced to the 5c., level with trading noted at this figure spot and contracts closed basis works freight as high as 5½c. Several important consumers have entered the market of late and in addition to this several of the producers have been buyers with the result that the market has presented more activity than at any period since last October when the famous slump occurred. The spot market has been fairly well cleaned up and offers have been rather restricted of late with the producers well in control of the situation once more. An interesting feature of the market during the fortnight was the announcement of several producers who are now quoting 3½c. basis 60% works for 1919 business. This price is considered high by consumers but producers claim the increased cost of labor, coal, lime and other incidentals warrants such a level. Business is reported to have passed at the level mentioned.

Soda Ash: This market did not respond to the upward trend in caustic until the past few days when an active inquiry developed for barrels and after a low period of selling the market advanced again to 3.10 and 3.15 f.a.s. The inquiry of late has been principally for export barrels. Bags have been neglected with trading at from 2.50 to 2.60. Dense ash has been tight at 3.75 double bags New York.

Copper Sulphate: Resales have depressed what should in the ordinary course of events be a rising market. Nichols 98/99% large crystals have sold as low as 8.50 although business has passed at 9c. and perhaps a trifle higher from certain quarters.

Cyanide of Soda: Some buying has been reported and the market was at one time up to 40c., but at the moment of writing 38c. can be done for domestic material.

Acetic Acid: This has been one of the features of the chemical market. Sales have occurred at such a wide variance that prices mean nothing. Locating supplies seems to be the main accomplishment and a consumer will pay most any price the seller demands. Prices really mean nothing as they change from hour to hour.

Sulphuric Acid: An easier feeling has prevailed owing to the fact that quite a few cars of 66 brimstone acid have appeared on the market ranging in price from $35.00 upward. Even at these prices buyers have not appeared interested. Sixty degree material has been offered at $25.00 sellers tanks works. Sixty-six brimstone acid is held at $40.00 drums works.

Oleum: This market has followed sulphuric and resales have been made at $70.00 drums and $65.00 tanks works.

Nitric Acid: As a result of the strong nitrate of soda situation the market is firmer and resale material at 8¾c. has been eliminated and little under 9c. can now be obtained.

Nitrate of Soda: Definite word from the government fixing the price at which nitrate of soda may be sold is expected. In the meanwhile the government frowns in resales but these have been occurring at prices ranging from 5.20 upward at various points. The market looks rather uncertain with a probability of higher prices.

Aqua Ammonia: Despite the government's desires there has been considerable trading but the trade is rather inclined to go slow and prices are somewhat lower than when last reported. Business has passed in 26 degree material at 25c. to 27c.

Sodium Nitrite: No particular activity is noted and resales have occurred at 33c. to 35c. A new producer offers contracts at 30c. f.o.b. works.

Bichromate of Soda: The market has been manipulated to a prouounced extent and short interests have been covering whenever possible without risking too much of an advancing market. Sales have occurred between 22c. and 25c., spot and works, and there is no telling what may happen from day to day.

Citric Acid: This has been probably the most fluctuating item in the chemical trade during the interval. An advance of 22 points was scored in one day. The product sold as high as $1.00 but at the moment of writing domestic material is available at 88c.

Acetic Anhydride: Consumers working on government requirements may secure material at $1.15 but outside consumers are compelled to pay from $1.50 to $1.60 for spot supplies.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

ALABAMA

BIRMINGHAM.—The National Steel Products Company is making rapid progress in the erection of a large new local plant to be devoted to the manufacture of steel castings. At the recent meeting of the board of directors, E. M. Kilby, who is vice-president of the Kilby Frog & Switch Company, was elected president of the National company.

ARIZONA

CHLORIDE.—The Hackberry Consolidated Mining Company is considering plans for the construction of a new mill for the treatment of its lead-zinc ore. The company is engaging in extensive development work at its properties.

COLORADO SPRINGS.—Poston & Blumfield have recently acquired extensive copper properties in the Squaw Peak district, near Clarksdale, and are planning for early development.

PRESCOTT.—The Copper Valley Mining Company, recently incorporated, and which acquired the Ehle claims in Skull Valley, has commenced development work, and it is said the company is contemplating the erection of a mill.

TOMBSTONE.—The Broskaw Mining Company is making rapid progress in the installation of compressors and other mining machinery at its properties. The company is considering plans for the construction of a new mill for the treatment of vanadium ore.

TUCSON.—The Pima Smelter & Refining Company, recently incorporated with a capital of $1 000,000, is planning for the removal of its furnace plant now in operation at Socorro, New Mexico, to a site now under consideration near the city. The company has already placed orders for its converter equipment.

MAMMOTH.—The E. W. Childs molybdenite properties on Copper Creek, near Mammoth, have been taken over by new interests for a consideration said to be about $200,000, and extensive development work is planned. In the past, the milling of the ore has been considered rather difficult, due to its copper contents, but it is planned to employ a new process whereby the copper will be eliminated by means of hydrochloric acid, and thereafter saved by electrostatic deposition, the molybdenum being left available for concentration by flotation.

ARKANSAS

HARRISON.—Ika Kilgore is having plans prepared for the construction of a new 100-ton concentrating mill for the handling of ores from nearby lead and zinc mines.

HOPE.—Operations have been inaugurated in the new plant of the Hope Fertilizer Company recently completed. It is planned to operate both the new and the old plants to supply the large demand for this product.

ROGERS.—M. F. Gurler, of Tulsa Okla., and H. C. Holderman, Joplin, Mo., have leased approximately 2,000 acres of local property and are planning to develop the copper deposits.

RUSH E. L. Standley, operating a local plant for the manufacture of ore concentrating equipment, is planning for the establishment of a branch works at Yellville.

CALIFORNIA

FRESNO.—The San Joaquin Light & Power Corporation has made application to the State Water Supply Commission for permission to appropriate a water flow on the Kern River for a new hydroelectric power plant. The proposed station will have a capacity of about 20,000 horsepower, and is estimated to cost $1,000,000.

MARICOPA.—The Trojan Oil Company is making rapid progress in the construction of a large new refining and absorption plant for the extraction of gasoline from gas in the Aaktop field, near Calgary.

MARTINEZ.—The Butters Chemical Company is rushing to completion its new local electrolytic zinc plant, and it is expected that operations will soon be inaugurated.

MARTINEZ.—It is reported that huge additions will be made to the local plant of the Hercules Powder Company, including several additional nitric and sulphuric acid units, and seven more units for the manufacture of T.N.T. The company holds large contracts from both the Army and Navy Departments and it is understood that the new works will give employment to about 4000 hands.

OROVILLE.—The Western Ore Company is planning for the construction of a new concentration plant at its chrome claims at Lime Saddle, near Oroville.

SANTA ROSA.—The American Products Company has recently been organized to operate in Sonoma County, and will engage in the manufacture of printing inks and dyes.

COLORADO

DENVER.—The Queen City Foundry Company is planning for the immediate installation of a new one-ton Booth-Hall electric steel furnace, to replace the converter equipment now in use. The furnace which is rated at 300 kva., has a holding capacity of three-quarters to one ton. The Denver Gas & Electric Company will supply energy for the operation of the furnace.

GEORGETOWN.—The W. J. Chamberlain Ore Company has announced that it will close and dismantle its sampling works at Georgetown, Breckenridge and Blackhawk. It is said that the shutdown is due to the high cost of operation.

DELAWARE

DELAWARE CITY.—The United States Government, Ordnance Department, is said to be negotiating for the purchase of a large tract of land at Port Penn, near Delaware City, for the construction of a large new shell-loading plant. The plant will give employment to about 5000 hands.

WILMINGTON.—The E. I. duPont De-Nemours Company is planning for the manufacture of pipes and auxiliary equipment used in munitions works, in the plant of the B. F. Shaw Company, Second and Lombard Streets, recently acquired.

CONNECTICUT

FORESTVILLE.—A portion of the plant of the Bryce Manufacturing Company, Fredericks Street, manufacturer of ball bearings, etc., was recently destroyed by fire. The loss is estimated at about $50,-000.

WATERBURY.—The American Brass Company has recently awarded a contract for the construction of a new one-story brick, steel and concrete addition to its plant, about 50 x 105 feet. The Sperry Engineering Company, New Haven, is the contractor.

GEORGIA

MACON.—Contract has been awarded by the Macon Gas Company for the construction of a new addition to its gas works to provide an increased capacity of approximately 10,000,000 cubic feet per month. The addition is estimated to cost $40,000, and is expected to be entirely completed by September 1. The Parker Russell Mining & Manufacturing Company, St. Louis, Mo., is the contractor.

IDAHO

KELTON.—The Mercher Mining Company is planning to inaugurate operations in its new 100-ton concentrating plant before the close of the month. This will also include flotation.

MURRAY.—The Miners Smelting & Refining Company has recently completed its organization plans and is contemplating the construction of a new plant on Coeur d'Alene Lake. C T Kennan, Murray is interested in the company.

BOISE.—The Northwestern Development Company has commenced the operation of the Ranger copper claims, about twelve miles east of Salmon, Lemhi County. The company is considering plans for the construction of a large new concentrating plant.

ILLINOIS

CHICAGO.—J. L. Sparks, West Grand Avenue, is making rapid progress in the construction of a new one-story foundry, about 50 x 75 feet, at 1723 Carroll Avenue. The structure is estimated to cost $10,000.

CHICAGO.—The plant of the Phoenix Hermetic Company, manufacturer of glass jars, etc., was recently partially destroyed by fire, with loss estimated at $18,000.

CHICAGO.—A new one-story foundry, about 175 x 225 feet, is being erected at Hegewisch, Ill. by the Western Steel Car & Foundry Company, One Hundred and Thirty-sixth Street. The structure will cost $50,000.

CHICAGO.—The Illinois Steel Company has completed the erection of extensive additions to its Gary plant, including four additional furnaces, ore docks, rolling mills, and a Bessemer duplex plant. These mills are now the largest single unit of iron and steel producers in the world, and the plant has been increased by about fifty per cent since the war. The entire work is estimated to have cost approximately $20,000,-000.

DECATUR.—The Leader Iron Works is making rapid progress in the construction of a new one-story addition to its plant, about 50 x 200 feet, to cost $10,000.

INDIANA

INDIANA HARBOR.—The Mark Manufacturing Company is planning to inaugurate operations in its new 80-inch plate mill at its North Harbor steel works at an early date. Construction work on other additions to the plant is progressing rapidly; the billet and blooming mills are expected to be completed within the next month, and the company will soon place in operation four open hearth blast furnaces. It is also expected to complete the construction of the coke ovens before the end of the year. About 4,000 hands will be employed for initial operations.

EAST CHICAGO.—The Green Engineering Company, South Kennedy Avenue, has had plans prepared for the construction of a new one-story foundry. The structure will be about 45 x 100 feet, and is estimated to cost $50,000.

IOWA

OTTUMWA.—The plant of the Morey Clay Products Company was partially destroyed by fire on March 19, with loss estimated at $25,000.

KENTUCKY

WINCHESTER.—The Ken-See Mineral Company, recently incorporated with a capital of $25,000, is planning for the development of fluorspar lands near Marion. The company will commence the installation of the necessary equipment at an early date. Fielding H. Yost is president.

LOUISIANA

LAKE CHARLES.—The Lambert Chemical Company, St. Louis, Mo., has broken ground for the construction of the first unit of a large new manufacturing plant. The company recently acquired a local tract having a frontage of 800 feet as a site for the location of the works.

NEW ORLEANS.—The E. Z. Opener Bag Company has acquired property fronting on Toulouse, Scott and Cortez Streets, about 120 x 329 feet, comprising five-story and four-story factory buildings and warehouse, and is planning for extensive improvements and the installation of new equipment to cost about $50,000, for the manufacture of paper bags. H E Westervelt is president

NEW ORLEANS.—The United States Sulphur Company, Inc., has filed notice of a change in its corporate name to the American Brimstone Company, Inc.

SHREVEPORT.—The Equitable Window Glass Company, Buckhannon, W Va., has taken over the plant of the National Window Glass Company, Cedar Grove, near Shreveport, for the establishment of a new manufacturing plant.

SHREVEPORT.—The Marine Oil & Refining Company is rushing to completion the erection of a new refinery at Cedar Grove, near Shreveport, and it is expected that operations will be inaugurated at an early date.

MASSACHUSETTS

CONCORD JUNCTION.—The plant of the Whitman & Pratt Rendering Company was recently totally destroyed by fire on March 21, with loss estimated at $150,000. A large quantity of fertilizer and many hundreds of cases of soap were also destroyed.

WORCESTER.—The Crompton & Knowles Loom Works, 93 Grand Street, have commenced the construction of a new one-story addition, about 55 x 185, at their plant. The structure is estimated to cost $20,000. E. D. Ward, 82 Foster Street, Worcester, is the contractor.

GREENDALE.—Fire, caused by an explosion, damaged the plant of the Shepard Manufacturing Company, manufacturer of ferrotype plates, to the extent of about $10,000, on March 28. The company had been engaged on some important work for the Government.

MICHIGAN

ALMA.—Operations have been inaugurated in the new local plant of the Ex-Cell-All Paint Company, and it is said that plans are under consideration for additions. The company was formerly located in Big Rapids and Marion.

DETROIT.—A new one-story plant, about 25 x 100 feet, will be erected by the General Aluminum & Brass Manufacturing Company, St. Aubin Street. The structure is estimated to cost $30,000. Contract has been awarded to the Austin Company, Cleveland, Ohio.

HOUGHTON.—The new 10,000 kw. power plant of Calumet & Hecla is rapidly nearing completion at its works on Lake Linden.

TWIN BRIDGES.—The Crystal Lake Mining Company is making rapid progress in the construction of a new concentrating mill at its properties.

MINNESOTA

BRAINERD.—The Brainerd Gas & Electric Company is planning for the construction of a new addition to its gas generating plant to cost about $10,000. It is planned to have the structure ready for operation by June 30.

ST. PAUL.—Plans are under consideration by the Gas Traction Foundry Company for the construction of a new one-story foundry, about 100 x 300 feet. The structure is estimated to cost about $65,000.

MISSOURI

ST. JOSEPH.—The plant of the Berry Foundry Company, Fifth and Oak Streets, was partially destroyed by fire recently, with loss estimated at $75,000. The company was engaged upon Government contracts. G. D. Berry is president.

ST. LOUIS.—The Tri-City Steel Company is planning for the construction of a new one-story steel rolling mills, about 100 x 200 feet, at Madison, Ill.

ST. LOUIS.—The Certain-teed Products Corporation has acquired a tract of land comprising about six acres on Union Avenue, between Brown Avenue and the Terminal tracks, as a site for the construction of a new plant for the manufacture of paints. The plant will be a four-story concrete building, and will have a capacity of about 4,000,000 gallons per year. Plans are now in course of preparation by Klipstein & Rathman, St. Louis.

ST. LOUIS.—The St. Louis Coke & Chemical Company is planning for the erection of a large new plant, including a by-product coke oven and two blast furnaces, on a site comprising about 300 acres recently acquired, near Granite City, Ill. The property was purchased for a consideration said to be in the neighborhood of $200,000. The new works will engage in the manufacture of toluol, ammonia, naphtha, benzol, metallurgical and domestic coke, gas, etc., and the project is estimated to involve an expenditure of approximately $5,000,000. L. E. Fisher is vice-president and general manager.

KANSAS CITY.—The Patent Vulcanite Roofing Company has had plans prepared for the construction of a new one-story addition to its plant on Twelfth Street, about 90 x 150 feet.

MONTANA

SALTESE.—The Tarbox Mining Company is planning for the early construction of a new 300-ton concentration mill. Richard Daxon is manager.

NEBRASKA

OMAHA.—The L. V. Nicholas Oil Company is having plans prepared for the construction of a large new refinery, to have a capacity of 1,000 barrels daily. The company has awarded a contract for the construction of a new 100,000 gallon tank to be located on property recently acquired at Twenty-fourth and Hickory Streets, comprising approximately nine acres.

NEVADA

MINA.—Frank Manson, connected with the Western Ore Purchasing Company, has acquired the old Candelaria silver mine, and is planning for the construction of a new 150-ton mill.

NELSON.—The Allard Mining Company is planning for the installation of a new tube mill and centrifugal amalgamator at the Carnation mine, for the treatment of high-grade ore.

NEW MEXICO

MOGOLLON.—The Socorro Mining Company has commenced the construction of its main mill building at its plant. Immediately upon completion of the structure, machinery will be installed, deliveries of which have started.

NEW JERSEY

NEWARK.—The Central Dyestuff & Chemical Company, Plum Point Lane, is having plans prepared for the construction of a nef reinforced-concrete addition to its plant. Marshall N. Shoemaker, 810 Broad Street, Newark, is architect.

NEWARK.—The Mono Service Company, Verona Avenue and Oraton Street, has taken out a building permit for the construction of a new brick factory, to be used as an addition to its paper products manufacturing plant. The works will cost about $15,000.

NEWARK.—The Heller & Merz Company, Hamburg Place, manufacturer of chemicals, etc., has had plans prepared for alterations and improvements in its plant.

NEWARK.—Fire, on March 24, caused by an explosion, destroyed three buildings at the plant of the Butterworth-Judson Corporation, Avenue R, manufacturer of chemicals, with total loss estimated at $200,000. The company is working on large Government contracts.

EAST ORANGE.—The Dunbar Sulphur Candle Company has filed authorization papers to operate at 65-67 Midland Avenue for the production of sulphur candles. William C. Lentz, 247 Clinton Avenue, West Hoboken, heads the company.

PLAINFIELD.—The Crescent Color Company, West Front Street, manufacturer of dyestuffs, etc., has commenced the construction of a new addition to its plant. The structure is estimated to cost $20,000.

MILLBURN.—Fire, on March 27, partially destroyed the plant of the Fandango Paper Company, Main Street, with loss estimated at $10,000.

TRENTON.—The Panther Rubber Manufacturing Company, of Stoughton, Mass., has recently purchased a factory building at the foot of Perrine Avenue for a consideration of about $25,000, and is planning to remodel and equip the plant for the manufacture of its products.

CAMDEN.—R. M. Hollingshead & Company, Ninth and Market Streets, manufacturer of soaps, greases, etc., have had plans prepared for the construction of a new three-story brick addition to its plant, about 60 x 150 feet, to cost $10,000.

NEW YORK

NEW YORK.—The Consolidated Metal Manufacturing Company, 130 Washington Place, has had plans prepared for the construction of a new one-story brick chemical manufacturing works to be located at Gold and Tillary Streets, Brooklyn.

NEW YORK.—The Central Smelting & Refining Company, 220 Rider Avenue, has filed plans for the construction of a new factory building, to be located in Canal Street, near Dairymple Avenue, Woodhaven, L. I. The estimated cost of the structure is $25,000.

NEW YORK.—The Knowles-Bradley Company, 88 Wall Street, refiners of saltpetre, has awarded a contract for the construction of a new five-story brick plant, about 100 x 165 feet, in Coffey Street. The works will cost about $36,000. H. G. Larzelere, Sycamore Park, New Rochelle, is the contractor.

COLLEGE POINT, L. I.—The L. W. F. Engineering Company, manufacturer of aeroplanes, has recently filed plans for the construction of a new one-story brick addition, about 210 x 250 feet, to its plant at Third Avenue and Eighth Street. Contract for the structure, which will cost about $15,000, has been awarded.

MOUNT VERNON.—The Triplex Safety Glass Corporation of America has acquired a tract of seven acres of land along the New York, New Haven & Hartford Railroad, for a consideration said to be $80,000, as a site for the construction of a new glass plant.

BUFFALO.—Fire, on April 2, caused by an explosion, destroyed a portion of the plant of the National Aniline & Chemical Company, Abbott Road, with loss estimated at $50,000.

OHIO

CLEVELAND.—The General Chemical Company, Warner Road, has awarded a contract for the construction of two new additions to its plant to cost about $20,000. A. A. Lane Construction Company, 1836 Euclid Avenue, Cleveland, is the contractor.

CLEVELAND.—Fire recently destroyed a portion of the plant of the Lennox Chemical Company, which was engaged in the manufacture of anesthetics for the American Red Cross. Quantities of acids and gas being manufactured for the Government were also destroyed. The loss is estimated at $100,000.

CLEVELAND.—The Lake Erie Smelting & Refining Company has filed plans for the construction of a new foundry addition to its plant at 3363 East Seventy-fifth Street. The structure will cost $18,000.

MASSILLON.—The plant of the Massillon Electric & Gas Company was partially destroyed by fire on April 3, with loss estimated at about $250,000.

NEWARK.—The Holophane Glass Company has awarded contracts for the erection of a large new experimental plant on Oakwood Avenue, comprising tank, lehr, and general factory buildings. It is expected that the plant will be ready for operation before the end of the summer.

SPRINGFIELD.—The Ohio Steel Foundry Company is planning for the construction of two new additions to its plant near Lagonda one to be one-story about 30 x 120 feet, to be used as a core room, and the other about 30 x 100 feet, to be used as a blast and repair shop. A new electric furnace will also be installed, of three-ton capacity.

OKLAHOMA

ELK CITY.—The Lucky Elk Mining Company has completed its organization plans, and will commence the development of about 40 acres of lead and zinc lands recently acquired.

PICHER.—The Picher-Oklahoma Mining Company is planning for the immediate construction of a new 800-ton mill at its properties. R. P. McReynolds is general manager.

PICHER.—The Crystal Mining Company is planning for the construction of a new 250-ton mill at its properties. B. B. Dancy is president.

OREGON

GRANTS PASS.—The Almeda Mining Company has awarded a contract for the construction of a new reduction plant at its copper-gold mine on Rogue River, near Grants Pass, the concentrator to have a capacity of 200 tons, and the blast furnace being of 150-ton capacity. The estimated cost of the plant is $200,000.

PENNSYLVANIA

GLENDON.—Fire, on March 25, destroyed a portion of the fertilizer plant of Berger Brothers, with loss estimated at $10,000.

PHILADELPHIA.—The Brown Instrument Company has just let a contract to R. C. Ballinger & Co. for an addition to its factory to cost approximately $50,000. This addition will be erected on the land which was purchased last fall at Wayne and Roberts Avenues, adjoining the present building.

PHILADELPHIA.—The Powers-Weightman-Rosengarten Company, manufacturer of chemicals, etc., has awarded a contract for the construction of a new one-story brick addition, about 45 x 60 feet, at 921-27 Brown Street.

PHILADELPHIA.—Charles Lennig & Company, Inc., 112 South Front Street, manufacturers of acids and chemicals, have had plans prepared for the construction of a new machine shop addition to their plant at Bridesburg, near Philadelphia, to cost about $17,000.

PHILADELPHIA.—W. H. & F. Jordan, Jr., Inc., 218 North Delaware Avenue, manufacturer of chemicals and allied products, has acquired the building at 124 Water Street, New York, for the establishment of a branch selling office. The new branch will be in charge of Warren E. Monroe.

The American Electrochemical Society and the South

THOSE who were fortunate enough to attend the National Exposition of Chemical Industries in New York last fall must have been struck with the exhibits made by Southern cities, railroads and industrial organizations. The impression was gained that not only was the South coming to the front, but that it had much to offer in substantiation of its claims for recognition. The material resources of the region were strikingly displayed, and there was tangible evidence that the South possessed and could produce a number of minerals that were much needed in this country, especially after the war disturbed foreign commerce.

We are inclined to suspect that those exhibits were real factors in the decision of the directors of the American Electrochemical Society to hold the next meeting in the South. Former invitations had not been lacking from this hospitable region, but always there seemed more pressing reasons for meeting elsewhere. This year, however, there could be no more appropriate combination, and since the decision was reached, the conviction has grown that no mistake was made.

The exigencies of war are bringing to fruition some of the cherished plans which Southern scientists and engineers have been trying for years to bring to the serious attention of the country. Confident that their region was destined to play a large part in national industry as well as in agriculture, and knowing the resources of mineral wealth and water power with which the South is favored, they were, nevertheless, unable until recently to impress the nation with the vital facts. Happily the deferred recognition is now at hand and those who have labored are to secure their reward.

No body of scientists and engineers is better able to appreciate the South's potentialities than is the membership of the American Electrochemical Society. Skilled in applying the electric current to metallic and non-metallic minerals, these gentlemen view broadly the fields of electrochemistry and electrometallurgy. They are interested in raw materials and electric energy, and since hydroelectric power offers certain marked advantages for their processes, they have a double interest in a territory that offers the combination of mineral wealth and water power. The South may well feel that in receiving this body of men and displaying to them her wealth, she is making valuable friends as well as entertaining appreciative visitors.

We have been glad to make an effort to serve both the Society and the South by presenting in this issue a summary of Southern resources contributory to electrochemistry and metallurgy. For the numerous contributions that make up the whole story, we are under

obligation to many busy men who responded to our request for coöperation. We believe the result justifies their efforts. We have here the background for a story that will be written in the future, a romance of industry in which will be woven the mineral resources, water power and engineering talent of a hospitable and chivalrous people.

Expanding Program of Nitrogen Fixation

IT HAS frequently been remarked during the course of the war that the United States is slow to get started, but once under way she will acquire a terrific momentum that will carry her through to a successful finish. The nitrate program is a case in point. For years a few knowing persons have preached nitrogen fixation in season and out, recognizing its importance to the nation in times of peace, to say nothing of its essential nature in war. But the words have fallen on deaf, or at least unappreciative, ears. Even within the period of the war there has been a failure to realize how largely we should go into nitrogen fixation, and our apparent needs now exceed by several times the most radical predictions of a few years ago.

The full program thus far announced is as follows: Plant No. 1, using the General Chemical Company's ammonia process, was built and will be operated by the Government at Sheffield, Ala. Plant No. 2, using the cyanamid process, is to be built and operated for the Government by the Air Nitrates Corporation, at Muscle Shoals on the Tennessee River, near Sheffield. Plant No. 3, according to a recent announcement credited to the War Department, is to comprise two units, located at Toledo and Elizabethtown, O. It is understood that Plant No. 4 also is to be built in the near future but the location is not yet decided upon. The two units of Plant No. 3 will have a combined capacity equal to that of Plant No. 2.

Although the location of the plants near Muscle Shoals on the Tennessee River was undoubtedly determined by the proposed hydroelectric developments there, it will be necessary to erect steam-electric plants for immediate use. Plant No. 1 will be served by the Alabama Power Co., which is now erecting a steam plant of twelve 1200-hp. Stirling boilers. Plant No. 2 will have twelve 1500-hp. boilers and two turbo-generators, one of 60,000 and the other of 7500 kw.

Truly we have been slow to get under way, but once started we are undertaking things largely. Some day the whole story will be written and it will make interesting reading.

Light in the Offing

THE appointment of John D. Ryan, president of the Anaconda Copper Co., as director of the aircraft program will be hailed with satisfaction and delight by the engineering fraternity of the country. Signs are multiplying that the Administration is profiting by the criticism of former appointments and is taking heed of sound advice and counsel. Following closely upon the announcement of the appointment of Charles M. Schwab to direct our shipping program, and Edward R. Stettinius in charge of purchasing for the War Department, the reorganization relating to aircraft production brings additional light and reassurance. Stettinius, Schwab and Ryan are synonomous with achievement and accomplishment, and are the type of men who have done things in a large way in business. We need more of their class in the conduct of the war, and it is to be hoped their number will increase. If the proposal to establish a minerals administration is carried out, it will be necessary to find a capable man to direct the work, and another opportunity will be given to make a wise selection. Some time ago when a Congressional committee reported on its investigation of delay in aircraft construction, it criticized the Administration for a policy of holding aloof from men who had special knowledge of certain branches of industry. The criticism was sound. Whether there has been distrust and suspicion of so-called big business, we do not know, but there is no doubt that we have lost immeasurably in time and production by failing to take advantage of that peculiar ability that has created and directed our largest industrial enterprises. No other nation has conceived and executed industry on such a huge scale. We have talent in abundance and variety, and of unquestioned patriotism. In our judgment it is the duty of the Administration to avail itself of such ability.

The Trend Toward Electric Brass Melting

READERS of this journal a decade and a half ago will recall that the rôle of the electric furnace in iron and steel metallurgy was then regarded as one of the most fascinating problems. Much speculation was indulged in regarding the future, but it was considered a safe prediction that the manufacture of special steels would be the line along which the electric furnace would make a successful bid for recognition. How complete that recognition has been is a matter of several years' record, for not steel alone, but pig iron as well has flowed from the electric furnace.

More recently the onward march of metallurgy has taken the electric furnace into the domain of brass melting, and the conquest bids fair to be complete. The main reasons underlying the economic change now taking place from fuel-fired to electric brass furnaces are to be found in the conservation of time, metal and fuel, improvement in the sanitary conditions of the foundry, and excellence in the strength and uniformity of alloys. The metallic loss, especially of zinc, is said to be lessened by at least one-half. With a thermal efficiency averaging perhaps seven times that of a fuel-fired furnace, the electric furnace affords a great saving even when using current from a steam-electric plant. With hydroelectric current the saving is infinitely greater. The saving of time and labor per unit of production is of material moment, especially under present industrial conditions.

There are on the market today over a dozen different electric furnaces for non-ferrous metallurgy, representing five different types, viz., induction, radiating-arc, direct-arc, resistance, and high-frequency. These are used for the production of a variety of metallic alloys which may be classified substantially as follows: (a) yellow brass with less than 3 per cent lead; (b) red brass and bearing-metal irrespective of the lead content; (c) red brass with low lead content; and (d) the aluminium mixtures.

The induction furnace is the type hitherto found most suitable for melting yellow brass with a spelter loss of one per cent or less. This is due to that characteristic of the induction furnace which permits accurate heat control, with consequent uniform temperature throughout the bath of metal. The advantage is obvious if it is desired to keep the volatilization of zinc at a minimum. Just recently the U. S. Bureau of Mines has perfected a new radiating-arc furnace which is said to be particularly suited to brass melting.

Class (b) alloys mentioned above are best melted in a furnace having a plain solid bottom devoid of all complications so that any lead which finally gets into the refractory hearth can do no harm even though it breaks through. The radiating-arc or the high-frequency furnace suggest themselves here and the former is thus much used and to some extent also the direct-arc furnace. The high-frequency furnace has not yet made its commercial appearance although it should fit in well in the non-ferrous industry, provided the cost can be brought reasonably low. Class (c) alloys give the least trouble, with comparatively low zinc content and little lead. The induction furnace lends itself to the production of red brass with low lead, less than three per cent; otherwise experience has shown that the lead may at any time percolate through the lining and damage the transformer coil. Class (d) alloys or high aluminium mixtures are formed readily with low loss in the resistance and radiating-arc furnaces. As far as known, these furnaces only are employed in this way commercially. High-nickel alloys are melted by all of the furnace types mentioned, and the best has yet to be determined. In general that furnace is being employed which gives not only the best metallurgical results, but which has also the simplest construction. Unfortunately these two features are not always coincident, as evidenced by the induction furnace which gives splendid results with yellow brass, yet its construction can hardly be called simple. Outside of the bottom-electrode type of furnace, all of the other electric furnaces which have reached the commercial stage are of fairly simple design and rugged construction.

Broadly speaking, the trend toward the electric furnace in the manufacture of brass and other alloys was heightened by the very poor sanitary conditions prevailing in many foundries where coke or oil furnaces polluted the air which the operators had to breathe. As the air remains clean with a properly chosen electric furnace, this characteristic alone was sufficient warrant for the investigation of electric melting devices. Other advantages have been found with later experience. The saving in labor is marked and the ability to keep experienced workers is pronounced. It is possible to keep better and more accurate records, have better technical supervision, turn out larger heats free from oxidizing influences, with almost absolute heat control and a very high thermal efficiency, approaching 80 per cent. All of these things observed in practice have so far induced the producer of non-ferrous alloys to install in the United States alone over 50 electric furnaces of different types, all of which are now operating and giving satisfaction to their owners. Plainly the trend is toward electric melting and the superiority of the electric furnace seems to be an accepted fact.

Will Dollar Silver Increase Production?

SEVERAL years ago it seemed that an enhanced price for silver was inevitable, since the rapidly expanding volume of the world's business was accompanied by only a moderate increase in the production of the precious metals, the shipment of gold and silver, of course, being the manner by which international credit balances could be leveled. The use of silver as a medium of international exchange received a powerful stimulus when Great Britain and the United States under war exigency embargoed the export of gold for this purpose except to certain governments. Enormously increased quantities of silver have therefore been exported from America to the Orient during 1917; China receiving twelve million dollars worth, double the quantity of 1916, and India absorbing $24,400,000, an increase of twenty-two millions. Add to this the quantities of metal coined to pay Allied troops, and the increasing amounts used in the arts, all producing an undoubted shortage of spot silver, which caused a continued rise in the price, rapidly culminating at $1.085 on Sept. 21, 1917. Cancellation of many orders on this runaway market caused a sharp recession, but the underlying demand must ultimately reappear. At the present time silver cannot be exported except under license; therefore there is no open market, and the price is held down by the lack of governmental purchases.

That Congress can act expeditiously when it so desires is shown by the fact that Senator Pittman's bill "to conserve the gold supply of the United States; to permit the settlement in silver of trade balances adverse to the United States; to provide silver for subsidiary coinage and for commercial use; to assist foreign governments at war with the enemies of the United States; and for the above purposes to stabilize the price and encourage the production of silver," was passed by both houses in short order. Debate in the Senate brought out the fact that the proposal "to assist foreign governments at war with the enemies of the United States" was the biggest factor in the whole plan, resulting from a demand by India against "the most important ally of the United States," Great Britain. Of the 350,000,000 silver dollars which are to be melted for export, Senator Owen admitted that the United States needed 50,000,000 "to take care of our jute from India alone."

The *modus operandi* of the bill as passed is as follows: The Treasury will remelt from its stock of nearly 500,000,000 ounces, 350,000,000 silver dollars, withdrawing the corresponding silver certificates from circulation and replacing them by an issue of Federal Reserve banknotes secured by United States gold notes. The mint will then proceed to re-stock the vaults by purchase of all available silver as fast as it is produced at $1.00 per ounce, again replacing banknotes by silver certificates.

Stabilization of conditions in Mexico would do much toward relieving the existing silver shortage, since in normal times she produced considerably more silver than the entire United States. However, this is apparently too much to ask; there is even little assurance that the estimated annual production of about thirty million ounces will materialize.

It is even doubtful that dollar silver will largely in-

crease the United States production beyond the present rate, which has been approximately stationary at seventy-four million ounces for the last three years despite the large increase in the market price. This idea is reinforced by a brief consideration of our present supply. About one-quarter of it comes from the refining of blister copper, which has enjoyed a fair price during 1917. As a consequence no sudden expansion in production of the red metal is to be expected. Another twenty-five per cent of the silver produced in the United States comes from the gold and silver mills. Here the full effect of the added price will undoubtedly be felt immediately in stimulating the output of the cyanide districts of Nevada and elsewhere.

The remaining production (practically half of the whole yearly output) comes from lead and lead-zinc ores. In this most important division, expansion of silver production will be much hampered by the divergent interests of the miner and smelterman. A large price for silver will tend to stimulate silver mining, but the lead smelters will continue to decline large increases in ore shipments. The smelter schedules are usually written so that the charge for treatment is assessed by paying the miner about four cents for the recoverable lead. If the lead market is high, the smelter profits. If the lead market is low, as at present, the largely increasing cost of labor, coke and usual repairs wipes out any balance on the smelter's books. Consequently, until lead prices advance in the face of increasing production, or ore contracts are rationalized, no great incentive for the smelters to increase their output of base bullion is apparent.

Iron and Steel in the South

"I WILL not say that Birmingham will furnish the world with iron, but I will say that she will eventually dictate to the world what the price of iron shall be."

The words are those of Sir Lowthian Bell—father of the present Sir Hugh Bell—on the occasion of the Iron and Steel Institute's memorable visit to the United States in 1890. Things move rapidly in the iron and steel industry, and if the prediction was to be fulfilled it ought to have been realized long ere this.

Not that Birmingham has done nothing. The state of Alabama, which is really not the whole of the Birmingham district, produced 2,953,705 gross tons of pig iron in 1917, making a new record, when most districts fell behind their output of 1916. Alabama's 1917 production was 32 per cent of the tonnage the whole country produced in 1890, when the prediction was made, and 37 per cent of Britain's production in that year, but Alabama's contribution to the pig iron output of the United States was 8.9 per cent in 1890 and only 7.6 per cent in 1917, showing a decline of 15 per cent in the proportion.

The prophecy, however, related not to tonnage but to price. As to price, it is well recalled that in 1897 Birmingham sold pig iron at prices that made producers in other districts, at home and abroad, stand aghast. The average market quotation on southern pig iron at Cincinnati in 1897 was $9.33. The freight rate from Birmingham to Cincinnati was $2.75 to May 1, 1917, and $2.25 thereafter, and allowing for this the average quoted price at Birmingham furnace would apparently be $6.91, but the computation is misleading, in that in those days freight rates were cut. On the other hand, sales were made, particularly for export, at under the quoted market, and thus it is probably not far wrong to say that Birmingham pig iron sold in 1897 at an average price of $7. Exports from the United States in that year were 262,686 tons, a large part of the iron coming from the Birmingham district. Incidentally, the present government price is $33.

Birmingham was not dictating, but was being dictated to. Furnaces lost money, and if their books did not show it the fault was in the accounting. The fates, however, had been against Sir Lowthian Bell in his prophecy of 1890. After the Institute meeting in Pittsburgh the visitors toured the country. They were in the Lake Superior iron and copper region October 15 to 18, and shortly afterward they returned home. No sooner were they safely out of the country than Alfred and Leonidas Merritt, on November 16, 1890, discovered the Mesabi range. Two years later the first Mesabi ore was shipped. The story of the range is familiar. By simple stripping operations enormous quantities of exceptionally rich ore were obtained, and it was literally sold as cheap as dirt in 1897.

There are many remarkable facts about the American iron and steel industry. Two of them are: (1) No large fortunes, made on the outside, have ever been put into the industry, except perhaps in certain isolated cases when the money was lost in unsuccessful experiments; (2) Until shares in the industry were mobilized by being listed on the stock exchange, practically no large fortunes were taken out. Yet the industry has made enormous sums of money. The deduction is obvious. Throughout its growth it has required the investment of great sums of money. The investments have very rarely been successful except when made by those who made the money in the industry, and without large earnings for reinvestment the manufacturer could not maintain the pace.

In 1897 the South sold pig iron at phenomenally low prices, and lost money. At the same time the Carnegie Steel Company sold steel at phenomenally low prices, and made money. For a time it borrowed from nearly every bank in Pennsylvania. The Southern producers could not borrow in their banks.

The Mesabi range rose and fell. The ores it is now shipping are very much less rich than those which made its reputation, for those rich ores are exhausted. With all the refinements, transportation costs are high. The Southern ores are as good as they were, and as years pass the competitive position, as regards quality of ore and coke, will improve for the South. Capital it certainly will be able to command much more freely than hitherto. Labor conditions in the United States produced by the war necessitate that in the future there must be much wider use of labor-saving machinery than there has been in the past. That probably will be to the advantage of the South, where inefficiency or scarcity of labor has exerted a restrictive influence. The South still has the natural advantages upon which Sir Lowthian Bell based his prediction. If the Mesabi range had not been discovered the course of American iron and steel development in the intervening 27 years might have been quite different.

Electrochemical Industry Essential to Winning the War

To the Editor of Metallurgical & Chemical Engineering

SIR:—The United States is now training over a million men to fight in France. Several million more will be trained. These men must have cannon, machine guns, rifles, shells, powder, cartridges, gases, airplanes, automobile trucks, and all other equipment of war in enormous quantities.

To manufacture these munitions high-grade alloy steel is necessary. For the preparation of the ferro-alloys used in making this steel existing electric furnaces are being worked to their utmost capacity. Numbers of new electric ferro-alloy furnaces are being constructed.

The vast quantities of abrasives which are so essential for the manufacture of machine guns, rifles, shells, automobile trucks, airplanes and all other machinery are almost all prepared in the electric furnace. In fact were it not for the electric furnace production of abrasives, it would be possible to produce only a small fraction of the vast amounts of machinery equipment for war purposes which are being turned out daily. The average man, unless he stops to consider the present manufacturing situation, has little or no conception of the fact that almost all fine machine work nowadays is finished in the grinder or with the use of abrasives.

For the manufacture of airplanes and auto trucks vast quantities of aluminium are required. This can only be manufactured by electrochemical processes.

Large quantities of the zinc necessary in manufacturing the brass used in the millions of cartridge cases made daily are recovered from the ore and purified electrolytically.

Many of the gases used for war purposes, i. e. hydrogen, chlorine, and bromine, are largely possible of preparation only by electrochemical means.

Many of the nitrogen compounds used for preparing the vast quantities of explosives required by our army and navy will be prepared with the aid of electrochemical and electrothermal processes.

Other basic materials such as magnesium, graphite, carbon electrodes, potassium chlorate, etc., which will be required in quantities can only be prepared with the aid of the electric furnace or electrolytic cell.

It is self evident to every thinking man that the electrochemical industry is essential to the winning of the war.

The war has resulted in a tremendous increase in interest throughout the country of all subjects having to do with chemistry and electrochemistry. The memberships of the scientific societies dealing with these subjects have increased tremendously. In view of these facts I think that your journal can well afford to emphasize the importance of the electrochemical industry to the country at large and also the fact that the interests of the electrochemical industry and the Electrochemical Society are identical, for in the Electrochemical Society are associated the men of the country who are pushing forward this work. Membership in the society affords the opportunity to stand shoulder to shoulder with the men, who foremost in their profession, are making it their business to see that the United States and her Allies receive the very best possible support from the electrochemical industry and all others related thereto.

The American Electrochemical Society is recognized as one of the livest scientific organizations in existence and is nationally renowned for the breadth of the discussions covering the papers and addresses presented at its two general meetings held each year in various parts of the country, which, combined with visits and special excursions to the more important centers of electrochemical developments are attended by the foremost electrochemists, engineers, metallurgists, chemists, manufacturers and central station men.

In existence for the past sixteen years, its membership of approximately two thousand extends throughout the entire world. Its literature is recognized as the only complete journal or "hand book" extant on the subject of electrochemistry. Its membership is open to those engaged in, affiliated with or interested in any way in electrochemistry and allied subjects.

The president of the society is Dr. C. G. Fink, well known for his development of the ductile tungsten used in the modern incandescent mazda lamp, and at present in charge of the research laboratory of the Chile Exploration Company.

The general secretary of the society is Dr. Joseph W. Richards, Professor of Metallurgy, Lehigh University, South Bethlehem, Pa., who as a member of the Naval Consulting Board is spending a large part of his time in Washington assisting with the work of this body, which by the way numbers among its members four past presidents of the American Electrochemical Society.

Electrolytic Pickling of Steel

To the Editor of Metallurgical & Chemical Engineering

SIR:—In your issue of March 15 Dr. Carl Hering makes some criticisms of work by Mr. Dodson and myself which appeared in your Dec. 15th issue, on Electrolytic Pickling of Steel. I should like to reply briefly to these remarks.

Dr. Hering's first criticism is that the chemical pickling did not last long enough, thus dissolving less iron than would normally be dissolved. In a former article[1] the object was to carry out the process in such a way as to make the electrolytic method appear to the best advantage; in this article, to the least advantage, as stated in the first paragraph, with the idea that actual practice would lie within these limits. For this reason the pickling was not continued beyond the point stated, where the scale was all removed except some very fine particles that could be completely cleaned off by brushing.

[1] Tr. Am. Electrochem. Soc 31, 181 (1917).

The second point is that in the chemical pickling the scale was filtered off before titrating the iron dissolved. In the first article all scale was dissolved before titrating; in this, none. In practice the results would lie between these two extremes.

The third criticism is that the acid was stronger than what Dr. Hering understands is used in practice in acid pickling, and not as strong as the patent calls for in the electrolytic pickling. Patent No. 827,179 states "good results" may be obtained with acid between specific gravities 1.15 and 1.25. Patent No. 855,667 recommends specific gravity 1.2. We used 1.19. I understand that 4.5% acid is used in chemical pickling. It was perfectly proper to use the strength that gives the best results in this comparison. This criticism is therefore entirely unjustified.

The fourth point is that the current density was not as high as called for by the patent. The patent (No. 855,667) calls for 40 to 70 amperes per sq. ft. Our current densities varied from 0.033 to 0.058 amperes per square centimeter or 30 to 54 amperes per square foot, averaging over 40 on the ordinary black plate; higher for the silicon-steel plates. This is within the limits specified by the patent. Dr. Hering's statement that the electrolytic process was not carried out properly is therefore not true.

Finally I believe these two investigations show the electrolytic method superior to the chemical method, and that this superiority increases with the thickness of the scale treated.

M. DE KAY THOMPSON.

Electrolytic Pickling of Greasy Surfaces

To the Editor of Metallurgical & Chemical Engineering

SIR:—The question has frequently been asked whether grease or oil on the surfaces of the steel would interfere when the scale is to be removed by electrolytic pickling, and whether the pickling removes this grease also. It was thought that the oil, being an insulator, would first have to be carefully removed, as in electroplating.

The writer therefore made the following tests: A piece of ordinary sheet steel covered with black scale was used; before pickling and while quite dry, a small part was painted over with mineral lubricating oil; another part with soft tallow; another part with linseed oil; and another part with lard oil. These oils and the grease therefore represented mineral, animal and vegetable oils; in each case they were well rubbed into the surface. The rest of the plate was left free from all grease or oil.

It was then pickled electrolytically in the prescribed way, by the Reed process, and it was found that the scale was removed quite as perfectly and quite as fast from those parts of the surfaces which had been covered with oil or grease as from those which had not; the oil and grease had disappeared completely, and on the cleaned surface it was not possible to find any indications of which of the parts had been oiled. The test was repeated many times, always with the same result. The oil was put on in as thick a layer as would adhere to a vertical plate, and the tallow was put on thick enough to show white. One of the plates was removed for inspection every five seconds but there was no noticeable difference between the reduction on the oiled parts and on the others. It seems that the hot nascent hydrogen or the current itself removes the oil and grease very effectively.

On removing the plates the water did not seem to wet them, indicating that they got a film of oil on them from the oil which had gathered on the top of the bath; this is an advantage rather than otherwise; and presumably it would not interfere with the subsequent tinning as such tinning baths often have a layer of oil over them through which the plate must pass before entering the tin bath.

It follows therefore that oil or grease, no matter how thick the coating, does not interfere in the least with electrolytic pickling.

Analysis of Ferro-Silicon

To the Editor of Metallurgical & Chemical Engineering

SIR:—I am sending herewith a condensed method of longer standard methods for the complete analysis of ferro-manganese. I have been using this scheme of analysis for some time with very satisfactory results.

A one-gram agate-ground sample is dissolved in 30 cc. of concentrated hydrochloric acid with the addition of a few crystals of potassium chlorate, and the solution evaporated to dryness. Take up with dilute HCl and filter off the silicious matter. The filtrate is taken to dryness a second time to render the last traces of silica insoluble. The two precipitates are carried through the usual silicon analysis. To the filtrate add ammonium chloride and boil. Precipitate the iron with ammonia. Dissolve the precipitate in dilute HCl and re-precipitate the iron twice in order to render the last traces of manganese in solution. After the third precipitation and filtration dissolve the iron precipitate in dilute HCl and titrate the iron with potassium permanganate (N/10 solution). The combined filtrates and washings from the iron separation are made acid with HCl and brought to a boil; then add 15 cc. of a 25 per cent solution of sodium-ammonium phosphate. While the solution continues to boil and with constant stirring, precipitate by adding concentrated ammonia drop by drop until a silky white precipitate of manganese phosphate is formed, after which enough of the ammonia is added to make the solution faintly ammoniacal. Remove from the source of heat and allow to settle a few minutes. Filter on a weighed Gooch crucible, ignite and weigh as $Mn_2P_2O_7$. The factor for manganese in this compound is .3869. If there is an appreciable amount of residue left in the crucible after completing the silicon determination, it should be fused with fusion mixture and the manganese determined by the sodium bismuthate method. Any result so obtained should be totaled with the manganese percentage. The carbon content may be obtained by the usual combustion method.

Middletown, O

Further Hearings on Federal Water-Power Bill

SIR Adam Beck, chairman of the Ontario Hydroelectric Power Commission appeared before the special Congressional committee on water-power bills on April 15 and spoke for five hours on conditions in Ontario. The hearings before the special committee will not close until Secretaries Baker and Houston have been heard, and there is some delay in prospect before a final bill will be drafted and presented to Congress. Members of the House, however, express confidence in the passage of a bill at this session.

In his address to the committee, Sir Adam Beck traced the inception and development of hydroelectric power in Ontario, beginning with the granting of franchises to the Canadian-Niagara Power Co. for 100,000 hp.; the Electric Development Co. for 125,000 hp. and the Ontario Power Co. for 180,000 hp. In 1900 the Board of Trade of Ontario initiated a movement to secure development privileges for municipal purposes. This was not considered favorably by the legislature, but in 1902 an act was passed authorizing municipalities to borrow money for light and power development. Difficulties were encountered in raising money, and rights were granted to the Electric Development Co. which had affiliated with it the electric light and street railway companies of Toronto.

In speaking of the present hydroelectric commission of which he is chairman, Sir Adam said:

"We have power to acquire by purchase or otherwise, on any terms, and hold shares in any incorporated company carrying on the business of developing, supplying and transmitting electrical energy. We have power to appropriate the land, waters, water privileges or water powers or works, machinery and plants or portions thereof of any person owning or operating under lease or otherwise or operating or using water-power privileges or transmitting electrical power or energy in Ontario which in the opinion of the Commission should be purchased, acquired, leased, taken, expropriated and developed or used by the Commission for the purposes of the Act."

At the present time the Ontario commission has acquired about 86 corporations, all by friendly negotiations and without resorting to the drastic powers delegated for that purpose. Contracts are in force with 225 municipalities. The form of contract is standard in all cases; the municipality pays all interest charges at 4% and a sinking fund of 1.8% which retires in 30 years. They pay line losses, depreciation charges, cost of operation, administration, etc. The average cost of power delivered to 225 municipalities in Ontario is under $18 per hp. The average rate is 2½ cents per kw.-hr.

"We operate at the present time twelve systems. They will become interconnecting eventually and form one great trunk system. In this way we are attaining the object of the whole scheme, namely, unit control.

Believes in Monopoly of Water Power

"We want to create a real monopoly because we believe all these service undertakings should be a monopoly. There is little satisfaction in having competition in a telephone system, or a telegraph system, or even a railway system, and certainly not in an electric system in any community. The obnoxious poles and wires, the great dual cost of everything, and the great dual investment that results because of the diversity created by these various corporations covering the same field is undesirable from every standpoint."

As to the Niagara situation, Sir Adam said the principle laid down by the International Waterways Commission is that there should be an equal division of water for power purposes on all international streams, and pointed out that there is now pending an application that the United States Government shall confer with the Dominion authorities regarding a proposal to allot another 10,000 second-feet to each government. This, he pointed out, is advanced as a war measure, and will be justified even though the most efficient use is not made of the water. Sir Adam said he believes that if this measure is carried through it would not be canceled after the war, but that the allotments would be permanent. He presented figures to show that the total power now being generated on both sides of Niagara is 653,500 horsepower. Of this amount, 265,000 horsepower is generated in the United States, which also receives 110,000 horsepower exported from the Canadian side, making a total of 375,000 horsepower available in the United States. This amounts to 40 per cent. more for the United States than for Canada although the latter country generates 100,000 more horsepower than the United States.

Present Conditions Unfavorable to United States

Comparing conditions on both sides of Niagara with relation to the establishment of electrochemical industries, Sir Adam pointed out the necessity of stabilizing prices for the encouragement of industry and said that under present conditions he thought industries would be more likely to go to Canada than to the United States. He was strongly in favor of government control of water power and intimated that nationalized control on our side of Niagara would do much to foster electrochemical industry in the United States.

The chairman of the commission went on to say that there is no intention on the part of the Canadian government or on the part of the Commission to interfere with the present export arrangement, even though Canada is now short 100,000 horsepower of the amount that country needs. In order to permit a continuance of the export, Canada has arranged to do away with all sign lighting, window lighting, and other uses of energy which in some quarters have been characterized as less essential. He said the power generated by the Province of Ontario has reduced coal consumption between 5,000,000 and 6,000,000 tons per annum. Motive power has been saved, use of cars has been saved, and duty on coal has been saved. The estimated potential horsepower of hydroelectric energy in Canada, Sir Adam said, is about 50,000,000, and in Ontario alone about 5,000,000 or 6,000,000, with but 700,000 developed. At the beginning of the Commission's work, in 1910, only 750 horsepower was being delivered to the twelve municipalities.

Speaking of the purchase of the Ontario Power Co., Sir Adam said that the commission expected to own the plant in 25 years, paying for it out of revenue from contracts with municipalities and with the Niagara-Lockport Co. Present contracts are at $9 per horsepower for 100,000 hp., and at $12.50 with the Niagara-Lockport Co. for 60,000 hp.

Secretary Lane Urges Water-Power Development

The Secretary of the Interior Regards a Constructive Program as a Vital Necessity to the Conduct of the War as Well as for the Future Extension of Our Electrochemical Industries

IF THE Congress of the United States is willing to commit the country to a program of federal development of water powers I see nothing impracticable in government ownership and operation of such utilities," said Secretary Lane in an interview with METALLURGICAL AND CHEMICAL ENGINEERING on the water-power question. "But," he continued, "under present conditions it seems more likely that immediate results will be secured through private initiative, and inasmuch as the quickest possible development is needed for the benefit of our electrochemical and other industries, both for war and peace, I am in favor of encouraging such a program. Owing to the tremendous demands now being made on the Government for funds it would seem unwise to adopt a policy of government ownership at this time. On the other hand, since there is a genuine demand on Congress for hydroelectric development, it is the duty of the Government to lend every assistance and to pursue a policy of fair and reasonable treatment of those who are willing to take the risk of investing money in such enterprises.

FRANKLIN K. LANE

The opinion of Secretary Lane on this question was sought not only on account of the general importance of the subject, but also because of the Secretary's wide experience in the administration of water power and related projects in the Department of the Interior. Continuing he said:

"The electrochemical industries of the United States have been found particularly essential to the conduct of the war, and yet they have not had adequate power. If these industries are to be fostered in this country and their extension made possible, it will be necessary to provide more power; otherwise we are confronted with the expatriation to more favorable localities of those industries which should be established here. More power should be developed at Niagara, and I believe that the United States and Canada should enter into an agreement for a large international development there that will make one million horsepower available to both countries. It would seem quite as feasible to secure the necessary legislation for this purpose as to negotiate a new treaty allotting to each nation additional water for private development.

"It is not at Niagara alone, however, that we need to develop water power. Our program should encourage development throughout the country wherever there seems to be a necessity for it and wherever we have mineral resources contributory to electrometallurgical industries. Some time ago I had prepared by the Geological Survey a series of maps of the Southeastern United States, showing the mineral resources of that region. It so happens that this same territory is rich also in potential hydroelectric energy. Some of it is developed but more will be needed as our industries expand with the normal growth of the country. We should realize that we need to undertake these developments immediately to meet war needs as well as to provide for future expansion. We have already witnessed wonderful progress in our chemical industry since the war began, and I believe we are on the verge of still greater expansion which will put this country in the lead. Prudence and foresight dictate that we should develop our water powers *now* in anticipation of the industrial growth that seems right at hand.

"Our neglect of water-power development in the past has been absolutely criminal, and in our present emergency we are discovering what it would have meant to us to have a great national resource well in hand. At a time like this we need to throw every resource we possess into the balance, and we have been woefully lacking when it came to water power. Of course the conservation of coal is an argument for water-power development, because much of our coal is used wastefully, and once used is gone forever. We ought to conserve our coal and use it in such a manner as to recover all the useful chemical by-products. Coal that is adapted to making coke should be used for that particular purpose and not as ordinary fuel. Another argument is the need of hydroelectric power for transportation on railroads—a problem which even now threatens to become acute next winter with its attendant fuel troubles. But to my mind the logical argument for water-power development is the folly of allowing a great natural resource to run to waste when it might be made to contribute so much to our industrial prosperity in times of peace and our national security when threatened with war.

"I have been deeply impressed with the importance of the chemist and the electrochemist, both in peace and war, and I realize the value of their contributions in meeting the problems forced upon us in our present emergency. It has given me a glimpse of the expanding romance of those sciences, as well as a vision of what the future holds for this country if we develop our resources to the fullest extent."

Director Manning Shows Importance of Electrometallurgy

Director of U. S. Bureau of Mines Emphasizes Vital Relation Between Hydroelectric Development and Electrometallurgy. Sees Expansion in Future Application of Electricity to Metallic and Non-Metallic Minerals

IF one looks at the relief map of this or any other country he cannot but be impressed with the large area of the earth's surface which is covered by hills and mountains, and unsuited to agricultural purposes, as compared to that which is so suited. At first glance one gets the impression that this is opposite to what it should be; but if we take into consideration the fact that the agricultural land of the earth by judicious and careful attention, may be made to yield food products continuously from year to year, while our mineral deposits, if once worked out, are gone forever, we come to the conclusion that after all it is a wise provision of nature that the proportion of the hills and mountains to the tillable land is as it is. These same hills and mountains serve as storehouses from which may be taken as needed, the ores which furnish the iron and steel which is used in the construction of our railroads, our steamships, our great buildings, and our machinery of every sort. From these same hills come the ores of the rare metals used in giving steel its special properties; the copper so essential to the manufacture of our alloys, and above all to the transmission of the electric current which can be most readily generated by the power afforded by the cataracts and falls of the rivers and streams.

VAN H. MANNING

In this connection, it is also well to remember that this source of power is perpetual. Although our coal beds may be mined and consumed, and although our metallic resources may be depleted, the water power of the country is, except where affected by the destruction of the forests, as great today as when man first set foot upon the continent, and, so far as we are able to judge at present, should remain so until the end of time. Although man early learned to harness the power of the water-fall and put it to use, it was not possible until electricity had been discovered, and ways and means of transmitting it perfected, to utilize the power of the water-fall at any great distance from its source. As the science of electrical engineering was developed it became possible to transform the latent power of the mountain streams into electric power capable of being transmitted hundreds of miles to light our cities, propel the cars along the streets, turn the wheels of factories, and in general make modern life possible. Although the discovery of electricity and the application of electrical engineering has done all this for us, it has also made possible the conservation of our coal; in other words it has extended the life of our fuel resources, especially for mining and metallurgical purposes.

Naturally, I am particularly interested in its use for the latter purposes, due to the fact that one of the principal functions of the Bureau of Mines is to conserve our mineral resources. As is well known, the use of electricity is becoming more and more extended in metallurgical work. Moreover, as is also well known, the application of electricity to metallurgical processes is comparatively recent. It was not until 1882 that it was probably first used by Siemens in electrothermic work, and its first application on a large scale for electrolytic purposes was perhaps in 1886 by Heroult and Hall, who in that year patented their processes for the production of aluminium. As late as 1898 the work of Stassano in producing pig iron in an electric furnace was looked upon more as something spectacular than as forecasting the important part which the electric furnace was to play in metallurgical work in the future; and it was not until 1900 that ferro-alloys began to be produced in the electric furnace. Taking into consideration this fact, and also the fact that today practically all ferro-alloys are made in the electric furnace, and that there are now two or three hundred steel furnaces making the same high quality of steel that it was formerly thought could be produced only in crucible furnaces, one is impressed with the rapid growth of the use of the electric furnace in the ferro-alloy and steel industry.

Electrolytic processes also are finding a more extended application as evidenced by the growth of the electrolytic zinc industry. In this day and generation it is not safe to predict just what may or may not be possible; but judging from the rapid growth of the application of electricity to metallurgical work during the past 20 years, it would seem safe to prophesy that electricity is only beginning to be applied to winning metals and non-metallic products from their ores, and that it will not be long until electrical processes will be discovered and applied to the treatment of those ores to which they are not at present applied. This seems true especially in the southern part of this country, to be visited by the American Electrochemical Society.

Proposed Minerals Administration Bill

A Synopsis of H. R. 11259 for the Control and Administration of Certain Special Minerals With a Particular View to Stimulating Production to Replace Import. Reported Favorably to the House by the Committee on Mines and Mining

AS MANY of our readers are undoubtedly aware, the War Minerals Committee has deemed it wise and necessary to propose national legislation for the purpose of securing adequate supplies of certain minerals, hitherto largely imported, and now essential to the production of munitions or for war industries. Under the direction of the Department of the Interior and with the approval of Secretary Lane, a bill was prepared and introduced in the House. Subsequently, hearings were held on the bill by the Mines and Mining Committee, and a favorable report has been returned to the House. It is reported in Washington that the Senate is likely to propose a bill differing in important details from that of the House, and that further hearings will be held by the Senate Committee. There seems to be agreement on the purposes of the legislation, but disagreement as to the methods of accomplishment. For the information of the industry we give a synopsis and comment on the sections of the House bill as seen by its proponents. With but two or three exceptions, the hearings developed a favorable attitude toward the bill. Opposition developed to the feature of price-fixing and to the possible interpretation of the bill to include the ordinary metals of which some of the unusual metals are by-products. As a substitute for the plan proposed by the bill, it was suggested that the Government organize a mining corporation and engage in business for the purpose of securing needed metals.

In the face of higher costs, unstable prices, transportation congestion, labor problems, and new taxes, increased domestic production is not taking place at a satisfactory rate. The bill plans to meet this situation in two ways. First: To increase production by stabilizing market conditions and eliminating part of the risk due to the uncertainty as to the length of the war; and second: where domestic production is not possible, to control consumption and prevent waste and nonessential use.

No Governmental body now has the authority which must be exercised to stimulate domestic production and to control effective distribution and use of these mineral supplies. The bill has been modeled after the Lever Bill, under which the President formed the Food Administration. The circumstances which justified the passage of that act are almost identical with those which now threaten to reduce the supply of these essential minerals. The bill provides authority to encourage the production of ores and minerals and to conserve their supply, to assure equitable distribution, to improve and direct utilization, to prevent manipulation, speculation, unfair practices and unequal division of profits, and to lessen our dependence upon imported materials.

Section 1 enumerates the minerals and their products which are included under the jurisdiction of the bill and which are defined as "necessaries." The minerals included represent those which have been formerly imported and whose supply is now uncertain due to shipping conditions, and in addition certain special minerals for which the demand for military purposes may increase beyond our visible supply.

The bill specifically defines "only the following named mineral substances and ores, minerals, intermediate metallurgical products, metals, alloys and chemical compounds thereof, to wit: Antimony, arsenic, ball clay, bismuth, bromine, cerium, chalk, chronium, cobalt, corundum, emery, fluorspar, ferro-silicon, fullers earth, graphite, grinding pebbles, iridium, kaolin, magnesite, manganese, mercury, mica. molybdenum, osmium, sea salt, platinum, palladium, paper clay, potassium, pyrites, radium, sulphur, tin, thorium, titanium, tungsten, uranium, vanadium, zirconium, and of other rare elements."

Section 2 authorizes the President, through the Secretary of the Interior, to take such steps as are necessary to carry out the purposes of the act and to create the necessary organization for this purpose. In view of the fact that this work will be of temporary war emergency character and must be carried out with the greatest dispatch, it is provided that persons may be employed without reference to Civil Service laws and regulations, as has been done under similar administrations which have been created.

Section 3 prohibits the agents or employees of the Government who are engaged in the carrying out of the provision of this act from soliciting contracts or from taking part in the letting of such contracts where they may have any financial interest involved, and provides penalties for the same, and in addition the forfeiture of any profits accruing as result of any action taken contrary to the provisions of this section.

Section 4 is a general section making unlawful certain acts which are covered in detail in the succeeding sections.

Section 5 provides for the licensing of the manufacture, storage, mining, distribution, and use of the "necessaries" specified in the bill. The licensing power is one of the most effective and necessary instruments for carrying into effect the provisions of the bill. There is considerable latitude left as to the method of licensing so that it might be possible to license any branch of the industries concerned either by general proclamation or by the issuance of individual licenses to every concern. It is assumed that the licensing power will not be used except where necessary. Due to the limited number of persons or concerns engaged in the production and distribution of the minerals specified, the number of licenses will be relatively very small, and consequently this feature of the bill will not cause any great expense or difficulty of administration. For example:—There are not over a dozen producers of sulphur, less than a hundred producers of pyrite, and not over two or three hundred producers of manganese. The provision for entry and inspection by duly authorized agents is essential to secure the necessary information with regard to compliance with licensing provisions and information dealing with consumption and prices. Authority is given to determine and establish just and reasonable returns to the various parties concerned in the production and distribution of the minerals involved. It is designed to correct an unequal division of profits between miners, brokers, smelters, and manufacturers, in order to insure adequate prices to stimulate production and at the same time to prevent an undue enhancement of the prices of products to be consumed.

Section 6 defines hoarding as the accumulation of supplies in a quantity in excess of the reasonable requirements of the business or when accumulated for the purposes of manipulating prices.

Section 7.—Hoarding has been defined as an unlawful act and this section provides a method of procedure in cases in which hoarding has been committed. The power to requisition conferred in Section 10 does not infer that an unlawful act has been committed and there is no penalty attached. On the other hand, if hoarding has been willfully committed, the person may be guilty of a violation of the law and becomes subject to condemnation proceedings. The evidence of hoarding is a question of fact which must be determined by a court or jury.

Section 8 provides a penalty for the willful destruction of "necessaries" as defined in the bill.

Section 9 provides penalties for limitation and restriction of output. Since the purpose of the bill is to stimulate production, this Section is primarily designed to prevent willful limitation of the supply and will not, of course, apply to ordinary commercial factors which discourage production.

Section 10 authorizes the President to requisition "necessaries" when required for the successful prosecution of the war and provides the means for justly compensating the owner. The necessity for this section lies in the fact that essential industrial and military requirements must first be met and that persons must be prevented, where a shortage exists, from diverting their products to non-essential uses.

Section 11 gives power to buy and sell and to make contracts for periods of not exceeding two years. The inability of producers to secure long time contracts for their product has contributed more than any other single factor to hinder new development. Uncertainty regarding the duration of of the war and the trend of prices thereafter discourages investment in any enterprise which is primarily based on war demands. It is obvious that if the power of purchase is granted, the powers to provide storage facilities and to sell must naturally follow. As long a contract period as two years is deemed absolutely essential because of the time element involved in opening new mines which usually takes a minimum of from four to nine months. No new contracts can be entered into after the termination of the war.

Section 12 empowers the President to take over and operate mineral deposits and plants which are either idle or insufficiently developed. While this power should be used as a last resort, it must be available for emergency. Such, for example, as where a deposit cannot be operated because of litigation, where the owners might refuse to develop the property, or where, because of its inaccessibility, private capital would be unable to operate it. The primary purpose of the bill is to stimulate development of necessary minerals by private capital wherever possible. This section is necessary to take care of any case where the other methods of stimulation provided might fail and where the output was essential. The section provides for the return of such properties as soon as the war necessity is over and for just compensation for any damage or depletion which may occur.

Section 13 provides for regulations to prevent speculation, manipulation of prices and unfair or misleading market quotations related to the minerals enumerated in the bill, and provides penalties for willful violation of such regulations.

Section 14 grants power to establish a guaranteed price in order to insure a reasonable profit to the producer and thereby stimulate production. Such guaranteed price may be for a period of two years. Considering the time element necessary to develop new mines and plants, two years is only a fair and reasonable time. Any shorter period would fail to accomplish satisfactory results in many cases. Sufficient latitude is allowed through regulations which may be prescribed in the establishment of guaranteed prices to make possible a sufficiently flexible handling of the problem to secure the best results. This section provides that duties may be placed upon the import of "necessaries" sufficient to bring the price of the imported article to the same level as any guaranteed minimum price which may be established under the bill. This provision is put in the bill for the purpose of protecting the United States Government. The Government having once established a guaranteed minimum price must, to make it effective, purchase such ores as are offered at that price, for the period of the guarantee which may be two years. In case of a sudden ending of the war, foreign "necessaries" might be imported at lower prices, unless this provision were made, thereby compelling the Government to purchase all domestic material at the higher guaranteed prices and increasing the liability of the Government to this extent. This Section further provides the power to fix prices. The establishment of a guaranteed price is essential to stimulate production, but additional price-fixing powers are necessary in order effectively to secure reasonable prices in any intermediate transactions between the producer and consumer. The section further provides that rules and regulations can be established with regard to methods of conducting business as supplemental to the licensing powers granted under Section 5. The necessity for control over methods of manufacture arises out of the possibility of a change in raw materials, or a scarcity of certain kinds of raw materials, or the use of substitute materials, which may require a change in practice. For example, in the steel industry it may be essential to revert to former practice and extend the use of the lower grade manganese alloys in place of the higher grade alloy formerly used which requires higher grades of ore than many of our domestic deposits will furnish.

Section 15 authorizes the curtailment of non-essential uses of the minerals covered in this bill in case a shortage of supply occurs which necessitates such action. For example, under this section it would be possible to prohibit the use of platinum in jewelry, or stop the use of tin for containers of dry substances.

Section 16 imposes a penalty for resisting an officer or employee enforcing the provisions of this bill.

Section 17 provides an appropriation of $500,000 for the administration of this Act.

Section 18 provides an appropriation of $50,000,000 to carry out the general provisions of this Act. This $50,000,000 is, in fact, a working capital which will enable the Government to enter the market and buy and sell the mineral products specified and to purchase any material which may be offered under the guaranteed prices established. This sum is not too large for the purpose, in view of the large liabilities which might be assumed under the bill. The value of the mineral products involved in the bill would be, at least, several hundred million dollars. While it is not contemplated that it will be necessary for the Government to actually purchase any considerable amount of the products whose prices may be guaranteed, a sufficient fund must be available to meet any possible contingency.

Section 19 provides that no employee under this Act is exempt from the provisions of the draft law.

Section 20 provides for annual reports of work done and details of expenditures.

Section 21 provides that if any part of the Act be declared invalid, such judgment shall not affect any other part of the Act.

Section 22 relates to the interpretation of the Act.

Section 23 provides for the termination of the provisions of this Act as soon after the close of the war as, in the judgment of the President, the agencies created can cease their activities and turn business back into its regular channels. While it is provided in Section 11 that no new contracts can be entered into after the termination of the war, it is obvious that it will take some time to settle the liabilities which may be contracted under the provisions of the bill and that consequently some organization will be required to terminate such business.

Bunker Hill Smelter Suits Ended

The suit filed last fall by the American Smelting & Refining Co. against the Bunker Hill & Sullivan Mining & Concentrating Co., and reviewed in our issue of Oct. 15, 1917, has finally been settled. Justice Wolverton at Portland has granted the preliminary injunction asked by the A. S. & R. Co., prohibiting the Bunker Hill company from smelting any of its own ores containg between 30 and 70 per cent lead. According to Stanley A. Easton, general manager of the Bunker Hill company, the adjustment provides for the future of this company. By its terms the ore produced will be divided equally between the two companies. Under the terms of the old contract the A. S. & R. company received ore containing 30 to 75 per cent lead, and the Bunker Hill retained ore having higher and lower contents. About 7500 tons a month will be available for division under the terms of the new agreement. The old rates charged by the A. S. & R. company have been readjusted so that the Bunker Hill will receive payment for a full 90 per cent of the lead content based on New York quotations and the grade of ore instead of the usual Coeur d'Alene contract, which provided for a split in price above $4.10 to the 100 pounds. The documents have been signed and the new arrangement will become effective at once. The suit will be dismissed if it has not been so disposed of.

SITE OF DAM NUMBER THREE, MUSCLE SHOALS

Nature's Gift to the Electrochemist at Muscle Shoals

By WILLIS G. WALDO

AFTER a ten years' struggle with the obstructionists and pseudo-conservationists, the 660,000 horsepower which since the dawn of the present geological era has been running to waste in the Tennessee River is about to be developed. That ten years should have been required to secure the development of this power is evidence which points with great emphasis to the difficulty of bringing fundamental economic truths to the intelligent understanding of the busy business man. If, for example, the city of New York could witness a 100,000-pound capacity car fully loaded with coal taken to a prominent dock and dumped into the Atlantic Ocean, could see this carload of coal followed by a similar car ten minutes later, and could see this performance repeated at ten-minute intervals thereafter, continuously, day after day, it may be safely stated that this waste would not long continue without a vigorous protest from thousands of citizens. But let these cars of coal be wasted at the rate of five tons per minute in the dashing waters of a great river by reason of its lack of development, as is true at Muscle Shoals, and let this water power be located in a section of the country more or less remote from public view, and ten years are required to bring about the necessary action to stop the waste.

But it has been accomplished, and under the direction of Col. Hugh L. Cooper, builder of the great Keokuk dam and a man of international engineering reputation especially in hydro-electric development, the first of the two great power dams is about to be constructed at Muscle Shoals in the Tennessee River. Before considering the significance of this undertaking to the American electrochemical industries a consideration of the dams themselves may be of interest.

Outline of Complete Project

The full project calls for three dams. Number one is a small structure, 15 feet high and 300 feet long, provided solely for the purpose of improving the navigable channel.

The greater of the power dams is Dam Number Two, about 104 feet high and 4500 feet long, which together with its 850-foot power house will contain 1,200,000 cubic yards of concrete. When it is remembered that the great Roosevelt dam on the Salt River in Arizona, 260 feet high and 680 feet long, contains only 240,000 cubic yards of concrete, and the new Croton dam of the New York water supply, 1200 feet long, contains 855,000 cubic yards of concrete, something of the magnitude of this greatest of concrete dams will be appreciated. According to present plans approved by U. S. Army engineers, the ultimate installation at Dam Number Two will amount to 480,000 horsepower and the electrical units will be giants in size, developing 40,000 horsepower each.

Fifteen miles upstream from Dam Number Two is the site of Dam Number Three, which though but 40 feet high will be 6425 feet long, making it the longest dam in the world for its length will exceed that of the great Assouan dam in the Upper Nile by 25 ft.

The motto of the famous builder in his construction work on Dam Number Two consists of but one word—Economy. The government has already provided for the emergency plants for the manufacture of nitrate at Muscle Shoals which will be driven by steam power and therefore it is regarded as unnecessary to increase the cost of the hydro-electric development by reason of undue haste. The government investment therefore will be held down to the lowest possible figure.

With respect to the cost of the power when developed it may be stated that estimates approved by U. S. Army engineers have placed the cost between $7 and $9 per horsepower-year, or less than 1½ mills per kilowatt-hour. This is contrasted with the cost of power at Niagara Falls which ranges from $10.50 to $20 or more per horsepower-year, or from 1.6 mills to upward of 3 mills per kilowatt-hour. True, industries already established at Muscle Shoals may require as much as 260,000 horsepower of this supply but it seems entirely likely that with the completion of the Muscle Shoals project 400,000 horsepower will be made available for the use of other industries at a remarkably low rate.

Retaining America's Leadership

It is well known that America leads the world in electrochemical products. Others may dispute American claims for leadership in other branches of chemical science, but in the field of electrochemistry and electro-

metallurgy the United States is admittedly foremost. The war is bringing to the American public a knowledge of the value of electrochemistry and electrometallurgy in a terrible lesson that will not soon be forgotten. Ignorance and indifference to the value of these key industries to our national welfare and existence have been responsible for conditions which have driven many important American electrochemical enterprises to other countries. As long ago as 1907 the American Cyanamid Company, after strenuous endeavors to secure a location on one of our great Southern power streams, was compelled to withdraw from the country entirely and locate on the Canadian side of Niagara Falls. Since that time hardly a year has passed that some important industry has not sought its greatest essential—cheap power—in the bleak northern lands of Canada and Norway.

But it now seems evident that the enlightened public opinion in America will assure our electrochemical industries that the supremacy which they have gained in spite of these handicaps shall not be taken from them, and evidence is not wanting in Washington that there is a growing appreciation of the value of Southern water powers and Southern resources in the expansion of these great industries.

SITE OF DAM NUMBER TWO, MUSCLE SHOALS

If throughout the length and breadth of the country Nature has provided a happy combination of advantages for the electrochemist, it is in the Southern Appalachians and the adjacent territory. Here is an abundance of water power, closely associated with mineral and other natural resources which for variety have no equal within a similar area elsewhere in the United States. From the Potomac on the north to the Alabama on the south there is not a single important Southern stream that is without its power section, and developments have been many, particularly in southern North Carolina, northwestern South Carolina and northern Georgia.

But while the eastern slope of the Appalachians is drained by a score of streams, the western slope is drained almost entirely by the many small streams which unite to form the majestic Tennessee. So it happens that the greatest of the power streams of the Southern states is the Tennessee River, and the greatest undeveloped power on the Tennessee River is at Muscle Shoals in northern Alabama where reliable government records covering a period of 72 years assure a conservative basis for dependable hydro-electric development. The advantages of this location for the electrochemist become evident when we inquire into the needs of electrochemical processes for producing the essentials that we all now know are among our most important national requirements.

Essential Electrochemical Industries

First and foremost we need within our borders, and preferably within the safety area fixed by the War College, the necessary plants for the fixation of nitrogen to provide nitric acid and ammonium nitrate for explosives, dyestuffs and fertilizers. The only method of nitrogen fixation which has seen commercial success on this side of the Atlantic is known as the cyanamid method, and no stronger endorsement for Muscle Shoals can be brought forward than the fact that here the government is expending $30,000,000 in a vast establishment for the fixation of nitrogen by this process. Other processes are also under development by the government at this point but it is a source of gratification that while developing these untried processes the government is proceeding along adequate lines by employing a well-known method in order to secure its immediate requirements.

The growth of the electric steel industry in the United States has been most remarkable. With but 42 furnaces in operation and building in January, 1915, there were 233 by the end of 1917, and America has become the leader of the world in electric steel manufacture, outdistancing all competitors by a wide margin, for Great Britain comes second with 150 electric furnaces installed and in operation in 1917.

Of especial value is cheap power in Southern steel making. For many years the South has labored under a severe disadvantage because of the high phosphorus and high sulphur content of its ores, because in making steel by the Bessemer process these impurities could not be satisfactorily removed. But the advent of the electric furnace equipped with an abundant supply of cheap power promises to revolutionize steel making in the South, for this furnace used for refining the molten charge of the open-hearth furnace yields an electric steel which acknowledges no superior and finds an equal only in the high-priced crucible steel.

Muscle Shoals is surrounded by iron ores of great richness and the reserves are estimated in the hundreds of millions of tons. For many years the Muscle Shoals locality has had its blast furnaces, and during the past year it has shipped many tons of pig iron to Illinois by water at less cost and in less time than the shipment could have been handled by rail. In shipping this iron in pig form to the Northern manufacturer, this section has but followed the economic error of other parts of the South, for it must be admitted, though without credit to the South, that the shipment of raw material from this section to other localities has been the common practice. With the advent of cheap power, with an abundance of raw materials, and with the unexcelled supply of labor, the time seems not far distant when the South will do far more of its own manufacturing.

Among electrically reduced metals, aluminium is claiming a most important part in meeting war requirements of the past few years. Aluminium manufacturers have been compelled to ship their raw materials from Arkansas to St. Louis and thence to Niagara Falls, more than a thousand miles, for reduction. Bauxite is found in many places in the South, for while the largest production in the United States is found in Arkansas, there are important deposits in Georgia, Alabama and Tennessee, and the development of cheap power at Muscle Shoals should make possible the establishment of a great aluminium industry in this vicinity.

A rival of aluminium that promises to surpass it in usefulness for many purposes is magnesium, which can be alloyed to produce a material as light as aluminium and yet, according to Dr. Fink, as strong as soft steel. The country rock in the Tennessee valley is largely magnesian dolomite, and one of the interesting problems for the electrochemist is the recovery of this promising metal from this tremendous supply of raw material.

Proximity of Power and Raw Materials

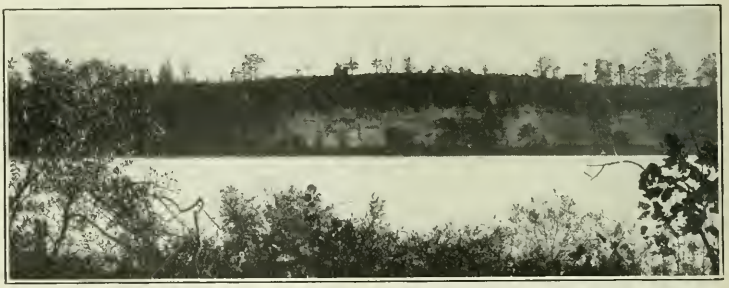
Equally fascinating is the recovery of potash from the high-grade potash feldspars which are abundant throughout the Southern Appalachians, and on good authority it may be stated that this problem has been reduced to one of the cost of power alone.

Valuable service has been rendered by the electric current in the refining of metallic zinc and the experience of the American Zinc Company at Mascot, Tennessee, is evidence of what is in store for the electrochemist when the South's resources are scientifically investigated. For many years the deposit of zinc at Mascot was regarded as comparatively unimportant but with the increasing demand and higher price of the metal the American Zinc Company undertook systematic drilling to investigate its properties and developed reserves of ore which justified the installation of a great modern concentrating plant. This is the type of investigation which is sorely needed in the South. We have had far too much guessing in dealing with our raw materials and the many disappointments which are charged against Southern developments may be fairly said to have been largely due to a lack of systematic investigation.

Those aristocrats of the metallurgical trade, the ferro-alloys, sometimes shipped by express in carload lots in these days of great demand, have already become established in the valley of the Tennessee. Both ferrosilicon and ferro-phosphorus are made in quantities within a comparatively short distance from Muscle Shoals although neither industry enjoys the advantages of $9 power.

High-calcium limestone and coking coal, so necessary for the manufacture of calcium carbide, are available in abundance, and cheap salt from the wells of West Virginia and from Louisiana provide the basis for chlorine, caustic alkali, sodium and a long line of other electrochemical products. The graphite fields of Alabama, hardly 150 miles from Muscle Shoals, afford a large and increasing supply of the raw material for electrodes, and the vast beds of phosphate rock hardly 60 miles from the Shoals, and which will soon be available by water transportation, offer to the master of electrochemistry a wonderful opportunity in the manufacture of phosphorus fertilizers and phosphorus metal.

In fact it is only necessary to refer to the map to observe the multitude of centers of commercial production of raw materials useful in electrochemistry and electrometallurgy which are found within the territory adjacent to the great power site at Muscle Shoals. Study of Southern resources has developed the fact that if a circle of 300 miles radius be drawn with Muscle Shoals as a center it will embrace a greater variety of commercially produced raw materials than is to be found in a similar area anywhere else in the United States.



LIMESTONE QUARRY SITE NEAR MUSCLE SHOALS

And when to an abundant supply of cheap power of great dependability and a large variety of raw materials there is added mild climate with its freedom from ice troubles in the power plants and where living is cheaper than in the more rigorous latitudes, and an abundant supply of suitable labor—for Muscle Shoals with its great government cantonments has already become an important labor center—and when it is remembered that here in great variety are factory sites having direct transportation by rail to nearby markets, north, south, east and west, and connection by water with the 14,000 miles of navigable streams which comprise the Mississippi River system, then it may be realized in a measure how commercially advantageous to the manufacturer is the location of Muscle Shoals.

Incombustible Celluloid in Japan.—According to Commerce Reports a noncombustible substitute for celluloid has been invented by a professor in a Japanese university, and a company has been organized for its manufacture. The factory buildings are now in course of construction, and it is planned to begin in April of this year, or soon after, the manufacture of waterproof cloth, and composition tiles, buttons and insulators. As soon as machinery ordered in the United States arrives, the manufacture of imitation leather, Linoleum, stained glass, marble, lacquers, and varnishes will be started. Patent rights have been obtained for linoleum, stained glass, marble, lacquers, and varnishes Japan and have been applied for in foreign countries.

Production of Electrometallurgical or Electrochemical Products Per Kilowatt-year*

VERY frequently the problem arises: A waterfall of x hp. is to be made available through transformation into hydro-electric power for the production of electrochemical or electrometallurgical products. What tonnage of products will it be possible to produce?

In a general way, on the shaft of the turbines only 80 per cent of the power of the waterfall is generated, calculated from its height and volume per second, this volume being carefully ascertained by an average annual figure resulting from numerous gaugings for rivers not provided with dam-reservoirs.

A new figure is next obtained by taking into account the losses suffered by the current before being utilized in the electric furnaces or in the electrolytic vat.

10% (on 80%) in dynamos, balance..... 72%
1% (on 72%) in the transmission line, balance 71.28%
3% (on 71.28%) in transformers 69.14%
1% (on 69.14%) in conductors 68.45%

Finally, supposing a waterfall of 5000 hp. is available, the current actually utilizable at the terminals of the furnaces or vat does not amount to more than $5000 \times 68.45 = 3422.50$ hp. Besides, in any electrochemical plant a number of accessory machines are used for the purposes of manufacture. For instance, in a calcium carbide, or ferro-silicon plant, there will be found crushers and grinding mills for both raw materials and finished products, conveyors, pumps, not mentioning even dynamos for lighting purposes, etc. All these apparatus are driven by electric motors which consume current amounting to one-tenth the power available at the plant. The figure of 3422 hp. is thus finally reduced to 3000 hp. and, of the 5000 hp. water power, only 60 per cent, or 2200 kw., is actually available for manufacturing purposes.

Supposing the current to be applied for the manufacture of electrochemical or electrometallurgical products, what can be obtained from one kilowatt during one year? To begin with, a statement must be made as to what is meant by the expression "kilowatt-year." It is not the power of one kilowatt utilized during 365 days of 24 working hours or 8760 kw.-hr. Actually, owing to accidents, inevitable interruptions for the inspection of the machinery, repairs, etc., even in plants intended for continuous operation, work is carried out during only 8000 hr. per year, and, thus, one kilowatt-year is equivalent to 8000 kw.-hr.

In the case of a plant which disposes of 2000-3000 kw. the following outputs may be obtained per kilowatt-year (meaning 8000 kw.-hr.):

Calcium carbide.....1600-1800 kg.

The output is reduced to 1000-1200 kg. in case small furnaces are used and is invariably above 1800 kg. in the large-sized furnaces consuming each 5000 to 6000 kw.

Ferro-silicon with 50% Si.....1000-1100 kg.

These figures are reduced to 1000 kg. with 1000-kilowatt furnaces operated with anthracite or coke. On the other hand, the figure is raised to 1200 kg. and even 1400 kg. with charcoal-operated furnaces.

Ferro-silicon with 75% Si.....500-600 kg.
Ferro-silicon with 90% Si.....350-400 kg
Ferro-chromium with 8% C.....800-900 kg.

This output diminishes rapidly according as the carbon-content is lowered since this is effected by successively remelting the high-carbon alloy in presence of chromium-bearing ore.

Ferro-nickel with 50% Ni.....300 kg.
(By reduction of an ore carrying about 5% Ni)
Ferro-tungsten with 50% W.....1000 kg.
Ferro-molybdenum .....900 kg.
Ordinary aluminium with 98-99% Al.....250-270 kg.
Aluminium nitride with 20% N.....1500-1800 kg.
Carborundum (crystallized).....300 kg.
Carborundum (amorphous).....500-600 kg.
Calcium nitrate (synthetic).....350 kg.
Caustic soda (electrolytic).....6-8 tons (metric)
Potassium chlorate.....6-8 tons (metric)
Chlorine (electrolytic).....6-8 tons (metric)
Pig-iron (high grade).....3-4 tons (metric)
(Starting from rich 50-60% ore and according to the nature of the reducing agent, whether coke or charcoal.)
Pig-iron (synthetic).....10-12 tons (metric)
(Obtained from steel turnings.)
Pig-iron (synthetic).....8-10 tons (metric)
(Obtained from a mixture of crop-ends, turnings and ore.)
Tool-steels .....20 tons (metric)
(Obtained from a liquid charge.)
Steel, high-grade carbon.....10-12 tons (metric)
(Obtained from a cold charge.)
Steel, refined in the electric furnace, 35-45 tons (metric)
(Obtained from a basic steel poured directly from converter into the electric furnace. The figure of 40 tons is double in acid operation, or .....80 tons (metric)
Steel, ordinary grade for casting..12-15 tons (metric)
(Cold charge with turnings.)
Iron, pure, electrolytic.....2 tons (metric)
Zinc, by electrothermic reduction.....1200 kg.
(Obtained by reduction of the ore in the electric furnace.)
Zinc, electrolytic.....2 tons (metric)
(Obtained by electrolysis of a solution of zinc salts from ore analyzing 30% Zn and 15% Pb.)
Copper, electrolytic.....90-95 tons (metric)
(Obtained by electrolytically refining crude copper.)
Copper, electrothermic.....2-3 tons (metric)
(By treatment of ore carrying 25% Cu.)
Sodium, metallic.....550 kg.
Calcium, metallic.....140-150 kg.
Manganese, pure.....140-150 kg.
Ferro-manganese, electrothermic.....10 tons (metric)
Silico-manganese and silico-spiegel...10 tons (metric)
(Output varying considerably according to composition of alloys.)
Magnesium .....300 kg.

In conclusion, it will be restated that these figures are only relative being essentially a function of the skill put into the operations, of the size and type of the apparatus, and, frequently, of the nature of the current.

RESOURCE MAP OF SOUTHERN STATES

Adapted from a Complete Map of the United States Prepared by the Nashville Section, Engineering Association of the South

Mineral Resources of the Appalachian South

A Symposium by Southern State Geologists on the Raw Materials Suitable for Chemical, Electrochemical or Metallurgical Development

A GLANCE over a map of the Southern States such as appears on the opposite page, on which has been indicated the location of important mineral-producing districts, will visualize clearly the importance of the Appalachian South in our present and future industrial life. Only the most important mineral products are here shown, but the full significance of the resources of this region can be gathered from the fact that of the 57 useful minerals produced in the United States every one is mined in the South except platinum and borax. Owing to the limitations of space the map does not show the pebble phosphate district of the Florida peninsula, which is first in importance in this country. The numerals in the shaded areas in the map indicate the relative importance in the United States of the regions producing the several mineral products. It will be seen at a glance that the area shown leads in the production of coke, pyrite, manganese, fluorspar, barytes, zinc, bauxite, sulphur and phosphate (not shown).

In an address on the industrial resources and opportunities of the South delivered by A. D. Little before the American Chemical Society at New Orleans, April 1, 1915, the speaker gave the following concise summary of the industrial position of the South:

"In general it may be said that the South to-day is in a far stronger position industrially than the entire country was in 1880. It cuts more lumber, mines nearly twice as much coal, produces nearly four times the petroleum, and nearly six times the spelter. It has more looms and spindles and a much larger investment in manufacturing plants. Its agricultural capital is greater and the products of its farms are worth fifty per cent more. It makes nearly twice as much pig iron and twice as much coke as the whole country produced only thirty-five years ago."

In another article in this issue by Richard K. Meade a comprehensive statement of the South's mineral resources is given and in the following paragraphs we present more detailed statements.

Mineral Resources of Alabama of Chemical and Metallurgical Importance

By Eugene A. Smith
State Geologist

These resources are here presented in the order of their relative commercial value.

Coal and Coke.—The Warrior field contributes about 84 per cent of the total production, mainly from the Brookwood, Pratt and Mary Lee groups, which produce most of the coking coal and more than half of all the coal mined in the state. The Cahaba field contributes something over 12 per cent of the state's total, and the Coosa field about 4 per cent. The total production of coal in Alabama in 1916 was valued at $24,859,831. The coke production was valued at $13,019,139, and the coke found local use in furnaces of the companies manufacturing it. Of the value above given $3,828,057 is credited to bee-hive ovens and $9,191,082 to by-product ovens. Of these the Tennessee Coal, Iron and Railroad Co. at Ensley operates 240 Semet-Solvay ovens, and at Fairfield 280 ovens of the Koppers type. The Woodward Co. operates 170 Koppers and 60 Wilputte ovens; the Central Iron & Coal Co. at Holt have 60 Semet-Solvay ovens active, and the Gulf States Steel Co. at Alabama City have in operation 37 Koppers ovens. These establishments, in addition to the coke, turn out tar, benzol, toluol, naphtha, ammonium sulphate and naphthalene, with a value about equal to that of the coal used.

Iron Ores and Pig Iron.—The iron ores in 1916 were valued at $10,843,231, and the pig iron produced from them was valued at $38,994,660, an instructive illustration of the great increase in value of even the first derived product over that of the raw material. Roughly speaking the red ore or hematite of the Clinton or Red Mountain formation constitutes something over 80 per cent of the total iron ore production of the State. The most important development of this ore is on East Red Mountain between Birmingham and Bessemer, but other important occurrences are around

Attalla and Gadsden, and localities to the northeastward. The soft red ore, as delivered to the furnaces, contains on an average, metallic iron 50.80, silica 18.50, alumina 3.65 and lime 1.20 per cent, while the hard or limey ore carries metallic iron 37.00, silica 13.44, lime 16.20, alumina 3.18, carbonic acid 12.24. When the lime content of the ore is equal to the sum of the silica and alumina the ore is self fluxing.

HIGH-GRADE POTTERY AND PAPER CLAY, BED 15 FEET THICK, LANGLEY, SOUTH CAROLINA

The brown ore, in 1916, represented about 18 per cent of the State's production. The usual mode of occurrence is in irregular concretionary masses in residual clays resulting from decay of Paleozoic limestone in the Appalachian valleys.

An average analysis of a good quality of brown ore as delivered to the furnaces in Alabama, is, as follows: Hygroscopic and combined water, 13.00; metallic iron, 48.54; silica, 11.22; alumina, 3.61 per cent.

Limestone, Clay, Lime and Cement.—The chemical and metallurgical uses of limestone are for Portland cement, for furnace flux and for lime-burning. The limestone for these purposes in 1916 represented a value around $2,000,000, the Portland cement industry claiming a good deal more than half of this value. At present only two Portland cement plants are active in Alabama, viz., the Standard Co. at Leeds and the Coosa Co. at Ragland, both utilizing the Trenton limestone and the Clinton and Mississippian shales occurring in close proximity. The Demopolis Co., utilizing limestone of the Selma chalk, and its residual clays, is at present inactive. A future possibility for this industry in the Coastal Plain region is in the St. Stephens limestone with nearby clays of Grand Gulf age.

The stone for furnace flux for many years was from the Trenton and Mississippian formations, but in the Birmingham District the dolomite of the Knox formation has been found to be superior to the limestone and is in general use. The average composition of the limestone is silica 3.50, oxides of iron and aluminum 1.00, carbonate of lime 94.6 per cent. The average composition of the dolomite is silica 1.25, oxides of iron and aluminum 1.00, carbonate of lime 54.0, carbonate of magnesium 43.00 per cent.

For lime-burning the stone of Trenton age is very generally used, the center of the lime-producing industry being in Shelby County, between Pelham and Calera. Other important plants are in Etowah and Jackson and Lee counties, the stone at the latter place is a crystalline dolomite of undetermined age. This lime, used for chemical, agricultural and building purposes represented in 1916 a value of nearly $300,000.

The chemical and metallurgical uses of clay are practically confined to the Portland cement manufacture and to the production of fire-brick used in the furnaces, statistical figures for which are not available.

Graphite.—The graphite field in Alabama extends from Chilton through Coosa and Clay counties into Randolph. The ore is a mica chist with average content around 3 per cent graphite. The most important developments at present are around Ashland in Clay county with, however, notable activity in Chilton and Coosa counties. The graphite industry has shown a remarkable development. Up to 1913 the production was less than 1,000,000 pounds from two or three companies. From 1913 to 1916 the number of active companies increased from two to seven, and the production from 2,020,000 to 5,226,940 pounds. In 1917 twenty-one companies were active, and in 1918 up to April 1, twenty-four companies were active producers, but we have not yet the figures of production. All the Alabama graphite is shipped into other states and used chiefly in the manufacture of crucibles and for foundry facings. Recent experiments have shown that the Alabama flake graphite can entirely replace the Ceylon mineral in the manufacture of crucibles.

STRIPPING BED OF SEDIMENTARY KAOLIN NEAR AIKEN, SOUTH CAROLINA

Pyrites.—At the present time known commercial deposits of pyrites are confined to a very limited area near Pyriton in Clay County where the ore, associated with an altered ignesous rock, occurs in lenses of varying size, averaging perhaps 10 to 14 feet in thickness of the ore, which in part is shiping ore, but in part needs concentration. A thin band in the orebody carries a small percentage of copper. For some years previous to 1917 there was no production of pyrites in Alabama, but in the year named three companies have been active, but the production is not yet available. Near Hightower in Clebourne County, a vein of copper-bearing pyrrhotite has been worked for copper, though nothing has been done here for many years.

Barytes.—Occurrences of barytes of commercial promise have been observed in Calhoun, Selby, St. Clair, Jefferson and Bibb Counties, usually in the red

residual clays from Trenton limestones and in the fissures in these rocks. The crude ore is shipped to outside markets, no barium products or barium chemicals being manufactured in the State. The production in 1916 by four operators was 7631 short tons, valued at $27,198.

OPEN CUT BARYTES MINE SHOWING SIX-FOOT VEIN OF ORE AFTER STRIPPING, KINGS CREEK, SOUTH CAROLINA

Bauxite.—The known commercial bauxite deposits of Alabama are in Cherokee, Calhoun and DeKalb Counties, where it occurs generally associated with kaolin in pockets, mostly near the base of quartzite ridges and bordering red-clay areas that have resulted from the weathering of Knox dolomite.

There being in 1916 and for several years before that, only one producer of bauxite in Alabama, the tonnage cannot be revealed. The raw mineral is shipped out of the State for the manufacture of metallic aluminium, aluminium salts, abrasives and refractories.

Mica.—Mica mines were opened in Alabama during the early days of mica mining in the Southern states. Considerable developments have been made at intervals during the last 20 years in most of the counties of our crystalline schist areas. In 1915 and 16 sheet mica of excellent quality has been produced valued at between five and six thousand dollars.

Mineral Resources of Georgia

By S. W. McCallie
State Geologist

The mineral resources of Georgia are both varied and extensive. The state is producing at present 34 different kinds of minerals in commercial quantities. This great diversity of mineral resources is accounted for in a large measure by the great diversity in the geological formations.

Asbestos.—The asbestos deposits of Georgia are chiefly to the Piedmont Plateau, where they are found associated with dark-colored, igneous rocks. There are two varieties of asbestos, the chrysotile and the amphibole.

The latter variety is extensively mined in Habersham and White Counties, near Nacoochee, this state. The White County mines here referred to have been the chief producers of asbestos in this country for several years.

Barytes.—The Georgia barytes deposits, which have so far been worked in a commercial way, are located near Emerson, Bartow County, and at Eton, Murray County. The mineral is largely used as a substitute for white lead. It is used also in the manufacture of paper, rubber, oilcloths, paper collars and barium salts, as well as for refining sugar, glazing pottery and for enameling iron. Georgia last year produced about two-thirds of the barytes mined in the United States, all of which came from the Cartersville district.

Bauxite.—The first bauxite found in America was discovered near Hermitage, Floyd County, in 1887. Later, deposits were found in Polk, Bartow, Gordon, Chattooga and Walker Counties, and between 1907 and 1915 deposits were found in the vicinity of McIntyre, Wilkinson County, near Andersonville, Sumter County and also near Warm Springs, Meriwether County. Since 1888 a high percentage of the bauxite mined in this country has been obtained from Arkansas, Georgia and Alabama.

Chromite.—Only two counties in Georgia, namely, Towns and Troup, as far as known at present, have chromite in apparently commercial quantity. The deposit in Town County is located two miles due west of Hiawassee, on lot 92; while the deposit in Troup County is near Louise. From the latter locality a limited amount of ore has recently been shipped. The ore in both localities is associated with ferro-magnesian rock and is generally found in the form of boulders in residual clays.

Fullers Earth.—The best known deposits of fullers earth occur near Dry Branch, Twiggs County, and in the vicinity of Attapulgus, Decatur County, where they have been worked for some years. Extensive deposits also occur in Bibb, Columbia and other counties near the Fall Line. The deposits of Twiggs County are now being worked by the General Reduction Company. Georgia stands second in the production of fullers earth, being exceeded only by Florida.

HIGH-GRADE PAPER CLAY, MENAMEE KAOLIN COMPANY, BATH, AIKEN COUNTY, SOUTH CAROLINA

Graphite.—Both amorphous and crystalline varieties of this mineral occur in Georgia. The amorphous variety is quite abundant in the neighborhood of Emerson, Bartow County, where it has been mined on a more or less extensive scale. Fine samples of crystalline graphite have been found in Bartow, Pickens, Elbert, Hall, Madison, Douglas, Troup and

DRYING SHEDS, GEORGIA SEDIMENTARY KAOLIN MINE. HEPHZIBAH, RICHMOND COUNTY, GEORGIA

Cobb Counties. All of the graphite material so far mined in Georgia has been used as a filler for commercial fertilizers.

Iron Ores.—Iron ores occur in Georgia in large quantities. The most common ores are the brown ores, or limonites, and the fossil ores, or hematites. Magnetite also occurs. The brown iron ores are most abundant in Polk, Bartow and Floyd Counties, but workable deposits are also to be found in nearly every county in the northwestern part of the state. The ores associated with the Weisner quartzite sometimes occur in ill-defined veins, but more generally they are found in the form of pockets or irregular deposits in the residual clays. The brown iron ores of the Knox dolomite series occur chiefly in the form of pockets or irregular deposits in the residual clays. The deposits are quite variable in size. Some of the individual deposits in the vicinity of Cedartown have been worked on an extensive scale for more than ten years without exhausting the supply.

The red, or fossil, iron ores of Georgia are confined to Dade, Walker, Chattooga and Cataoosa Counties. These ores occur in the Red Mountain iron ore-bearing series, which is so well developed near Birmingham. These ores occur in contiuous beds varying from a few inches to several feet in thickness. Some idea may be had as to the abundance of the red fossil iron ores of Georgia when it is stated that the aggregate length of the outcroppings of the beds, which average more than two feet in thickness, is approximately 175 miles, and that in many places the ore can be economically mined to the depth of several hundred feet.

Manganese.—The manganese ores, like the brown iron ores, are confined chiefly to Bartow, Floyd and Polk Counties. The largest and most productive deposits are found in the vicinity of Cartersville, where the ores occur as irregular deposits in the residual clays derived from the Beaver limestone and the Weisner quartzite. The manganese deposits of Georgia have been worked almost continuously for many years. During their early workings the ores were shipped to England, but in the last few years they have found a ready market in this country, where they have been used in the manufacture of steel and for bleaching powder.

Mica.—Mica is widely distributed throughout the Piedmont Plateau. It has been worked to a limited extent in Upson, Cherokee, Lumpkin, Union, Hall and Rabun counties. Some of the most promising prospectsin Cherokee County are in the vicinity of Holly Springs and Toonigh, and in the Hickory Flats district about ten miles southeast of Canton. The Lumkin and Union County deposits, as so far developed, occur near the Lumpkin-Union county line. Upson County is now an active producer as well as Meriweather County. Mica has been mined in Rabun County at the Kell Mica Mine, 10 miles east of Clayton, and in Hall County, near Gainesville. In addition to these localities, good mica prospects are found in a large number of other counties in the Piedmont Plateau.

Ocher.—The ocher mines of Georgia produce more than one-half the yellow ocher output of the United States. These mines are located near Cartersville, Bartow County. The deposits are confined to a narrow belt about eight miles in length and less than two miles in width. The most extensive workings are those of the Georgia-Peruvian Ocher Company, situated on the left bank of the Etowah River, two and one-fourth miles east of Cartersville. Ocher mining in the Cartersville district had its beginning in 1887. In 1890, the Georgia-Peruvian Ocher Company began operations on an extensive scale, and later, three other large ocher plants were put in operation.

The total maximum output of these four plants is estimated at about 1,000 tons per annum.

The principal use made of the yellow ocher mined in Bartow County, up to the present time, is in the manufacture of lineoleums and oilcloths. The important markets are England and Scotland. It is also used to a limited extent in the manufacture of paints.

Potash-Bearing Slates.—Slates containing 7 to 10 per cent potash occur north of Cartersville, Bartow County, in a belt 15 miles long and 1 to 4 miles wide. The best exposures are near White, on the L. & N. Railway, where a thickness of several hundred feet of such material may be worked by open-cut methods. It is believed that these slates are exceptionally fine raw material for the extraction of potash for fertilizer and other purposes.

Pyrite.—This mineral occurs in commercial quantities in a number of counties. The most important deposits are in Lumpkin, Cherokee, Paulding, Cobb, Douglas, Harlson, Carrol, Towns, and Rabun counties. Mines operating in 1917 were the Chestatee mine, six miles northeast of Dahlonega, Lumpkin County; the

SOAPSTONE MILL AND STOCKYARD, OLD DOMINION CORPORATION, ALBEMARLE COUNTY, VIRGINIA

Standard mine near Creighton, Cherokee County; the Little Bob and Shirley mines near Hiram, Paulding County; the Marietta mine near Marietta, Cobb County; the Sulphur Mining & Railroad Company mine in Douglas County, and the Waldrop mine near Draketown, Haralson County. Other promising deposits, which have been worked in the past or rather extensively explored are Reeds Mountain, near Bremen, Haralson County; the Southern Star mine, four miles west of Woodstock, Cherokee County; the Swift mine near Draketown, Haralson County; the Swift or Blake mine at Creighton, Cherokee County; the Canton Copper mine, Cherokee County; and the Mammoth mine near Hiram, Paulding County. The copper ore from Mine No. 20, Fannin County, is also a source of sulphuric acid.

Sericite.—Sericite of exceptional purity occurs in Pickens County only a short distance west of Jasper, where it is found in beds from a few inches to six feet or more in thickness, interlaminated with quartz schist.

The mineral is a variety of mica made up of small elongated silver-colored shreds. It resembles talc very closely, in physical properties, and is often used for the same purposes.

The Pickens County sericite has recently attracted considerable attention as a raw material for the extraction of potash. Two different companies are now mining this material with a view of extracting the potash for fertilifier purposes.

Mineral Resources of Maryland

By Edward B. Mathews
State Geologist

Maryland is rather a center of supplies and refinement of mineral resources than a source of the raw materials. It was, however, the early finding of chromite, magnetite, copper, and iron in this region which led to the establishment of many of the larger industrial plants of Baltimore and vicinity. The presence of extensive deposits of serpentine carrying more or less chromite, the abundant distribution of pegmatite dikes with potash and soda spar, and the presence of extensive clay deposits including lenses of kaolin serve as the bases of industries in each of these mineral resources, and stimulate more or less prospecting for new or richer deposits. The large industries of coal, brick and tile, and cement are too well known to need further comment.

BLOCKS OF SOAPSTONE AS TAKEN FROM QUARRY—OLD DOMINION SOAPSTONE CORPORATION, ALBEMARLE COUNTY, VIRGINIA

MINING MANGANESE ORE WITH STEAM SHOVEL, NEAR FRONT ROYAL, VIRGINIA

Chromite has been the subject of renewed investigation and from prospects at one or two points small shipments may be expected. The bodies, however, are small and the tenor in available chrome generally 40 per cent or better. The material is found in place and also collected along stream bottoms.

Feldspar deposits have been prospected and there are a number of operations especially in the Patapsco Valley in the neighborhood of Marriottsville and Woodstock and in Cecil County in the vicinity of Rock Springs. The material of the first area is potash spar, that of the second rich in soda. The smaller operations are feeling the lack of labor supply more perhaps than larger industries.

Clay has been one of the chief mineral products of Maryland since pre-Revolutionary time and the products have covered quite a range. At present, however, the industry is largely limited to the production of brick and tile and refractories with some enameled ware. Attempts at the present time are being made to develop blends consisting of Maryland and Tennessee clays to meet the shortage of German and English supplies.

North Carolina Minerals

By Joseph Hyde Pratt
State Geologist

Within the borders of North Carolina is found a wide variety of minerals, and, with the exception of perhaps one or two other states, a greater variety than in any other state in the Union. While most of these are of little or no economic importance, several of them are of large commercial value, and, of a few, North Carolina is the chief producing State. The principal mineral resources of the State, however, are building stones and clay products. Of the several minerals the following represent those of commercial importance that are now being produced in the state.

Metallic Minerals

Iron.—The principal iron ores of North Carolina are magnetite, hematite and limonite, the most valuable being the magnetites in Mitchell and Ashe counties, carrying from 31.16 to 68.34 per cent metallic iron.

These are exceptionally pure ores and make a very high grade of pig iron. The producing mines of limonite at the present time are in Madison and Cherokee counties. This ore is produced largely by open cuts. The most promising deposit of hematite is at Bessemer City, Gaston County, and ore was formerly mined and shipped to Birmingham, Alabama.

Copper.—The copper ores are composed pricipally of the sulphides and in the Blue Wing district of Person and Granville counties the ores are mostly chalcocite and bornite. In the Gold Hill district of Rowan, Stanly and Cabarrus counties, the ore is principally chalcopyrite. This is also true of the Cullowhee belt in Jackson county. In the Ashe County copper belt, which contains one of the most extensively developed mines in the State, the ore is composed of a mixture of chalcopyrite, pyrrhotite and some pyrite. Another belt in Swain and Graham counties is known as the Hazel Creek copper belt. At these two latter localities, considerable native copper has been found.

The mines of the Gold Hill district are auriferous pyrite and chalcopyrite with which is more or less gold-bearing quartz. The latter is the only gangue mineral of any importance. In the Cid mining district of Davidson County, the ores at the Silver Hill mine consist of a complex mixture of galena and sphalerite together with pyrite and chalcopyrite, the whole carrying silver and gold. At the Conrad Hill mine, the ores all consist of auriferous pyrite and chalcopyrite in a gangue of quartz, siderite, and hematite; and at the Emmons mine, the ores are auriferous pyrite and chalcopyrite in a quartzose gangue or as narrow stringers in the schists with little or no gangue.

Gold and Silver Ores.—The gold ores consist of free-milling and sulphide ores. The larger deposits of free-milling ore occur in what are known as slates and some of the difficulties encountered have been the separation of the very finely divided gold from the slates, which have some tendency to slime. In some of the mines the gold is rather coarse and little difficulty is experienced in saving it on plates. The lower portion of these deposits runs into the sulphides.,,The principal gold region of the State is that known as the "Carolina Gold Belt," extending across the central Piedmont region of the State running from the Virginia line in a southwesterly direction across Person, Orange, Guilford, Randolph, Davidson, Davie, Rowan, Montgomery, Stanly, Moore, Cabarrus, Mecklenburg, Catawba, Lincoln, Gaston, Cleveland, Union, Caldwell, Burke, McDowell, Rutherford, and Polk counties.

There is very little silver associated with the gold and the gold bullion is in a high state of fineness, running to 997. There is more or less silver associated with the copper ores of the State. There are but two silver mines known at the present time in North Carolina, the Silver Valley and the Silver Hill mines in Davidson County. The original ore in these mines is a mixed sulphide and in the upper portions of the vein where the sulphides have been decomposed, mining was carried on very extensively. When, however, the unaltered sulphides were reached, they were found to be composed of pyrite, chalcopyrite, galena and sphalerite, and on account of the complex character of the ore, it could not be profitably treated, and therefore mining operations were suspended. It is believed that now these complex ores can be separated and the ore bodies worked profitably.

Tin.—The most promising tin deposit in the eastern United States is near Lincolnton, Lincoln County, North Carolina. Casseritite, tin oxide, occurs in a decomposed pegmatite dike and, by working the deposit as a source of kaolin and saving the tin as a by-product, it is believed this property could be worked profitably. The tin ore occurs usually near the contact of the dike with the country rock and forms approximately ½ of one per cent of the contents of a width of 4 to 5 feet in the dike.

Chromite.—The principal chromite deposits are in Yancey County, and these are now close to railroad transportation. These deposits contain some of the highest grade chromite known, the Ray mine carrying ore running as high as 58 per cent chromic oxide per ton. Other promising deposits occur near Webster, Jackson County. These deposits are the most promising sources of supply of this mineral in eastern United States.

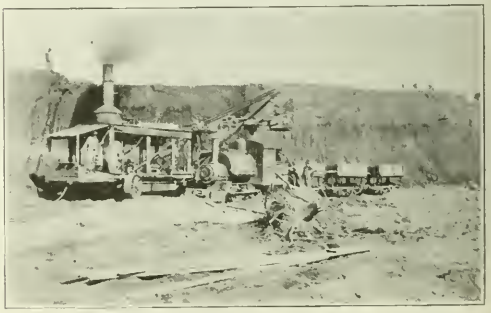
Manganese.—More or less manganese is found associated with many of the limonite iron ores. The most promising deposit is in Surry County where a property has recently been opened, but no quantity of ore has thus far been mined. An analysis of this ore gave 42.87 per cent of metallic manganese.

Non-Metallic Minerals

Corundum.—North Carolina was formerly the chief corundum-producing State in this country, but for several years very little of this mineral has been mined. The corundum deposits in Clay and Macon counties represent probably some of the largest deposits of crundum in this country. The corundum is of splendid quality.

Mica.—North Carolina mica has been known for years as "standard mica" and is considered the best grade of mica on the market. Many of the western counties contain mica in commercial quantity and its production has been constantly increasing for several years. It occurs in pegmatite dikes and is produced in the following counties: Mitchell, Macon, Jackson, Yancey, Haywood, Transylvania, Avery, Watauga, Ashe, Cleveland, Buncombe, McDowell and Stokes.

Monazite is found very extensively in the gravels of Cleveland, Rutherford, Burke, Polk, Lincoln, Catawba,



MINING BROWN IRON ORE WITH STEAM SHOVEL, RUSSELLVILLE, ALABAMA

McDowell, Gaston and Alexander counties. All the production is from placer mines. The gravels are washed and the concentrates cleaned magnetically so that the final monazite product contains approximately 95 per cent monazite. The most notable occurence of monazite in this country is near Mars Hill, Madison County, North Carolina, where in a pegmatite dike masses of nearly pure monazite were found weighing as much as 60 pounds.

Zircon has been found in commercial quantity in Henderson County in one of the pegmatite dikes. The commercial demand is small, and for a good many years one property has been able to furnish the entire known demand for this mineral in this country, its use being in producing zirconia for use in the manufacture of the glower for the Nernst electric lamp. It also occurs in some quantity near New Sterling, Iredell County.

Barytes is being mined in Madison and Gaston counties. It is a hard, compact variety of very high grade. It is usually granular in structure, but occasionally masses of some size are obtained made up of cleavable blocks.

Talc.—There are several localities in North Carolina in which talc occurs in commercial quantity. The most noted locality is the Hewitt mine in Swain County, which furnishes an exceptionally high grade of talc such as has not been produced at any other mine in this country. A splendid grade of talc also occurs in Cherokee County, and the soapstone variety occurs in Madison and Ashe counties. Pyrophyllite is mined in some quantity in Moore County and is used for some of the same purposes as talc. It has very similar physical but different chemical properties, it being a hydrous aluminum silicate.

Feldspar.—The potash variety of feldspar is now being mined in some quantity in Mitchell, Yancey and Watauga counties. The feldspar occurs in pegmatite dikes, usually in such form that it can be readily separated from the associated minerals. It is ground before being shipped.

Rare Minerals.—Several uranium minerals, such as uraninite, gummite, uranatil, and uranaphane are found in small quantity associated with some of the pegmatitic dikes of Yancey and Mitchell counties. The uraninite from the Flat Rock mine has the highest radio-activity of any uranium ore tested, according to Dr. B. B. Boltwood of Yale University. Several of the rare earth minerals have been found in some quantity in these pegmatitic dikes, such as samarskite, columbite, fergusonite, monazite, euxenite, hatchettolite, yadolinite, allanite and polycrose.

SOAPSTONE QUARRY SHOWING CHANNELING MACHINES —PHOENIX, NELSON COUNTY, VIRGINIA

Electrochemical Industries in Tennessee

By L. C. Glenn

Acting State Geologist

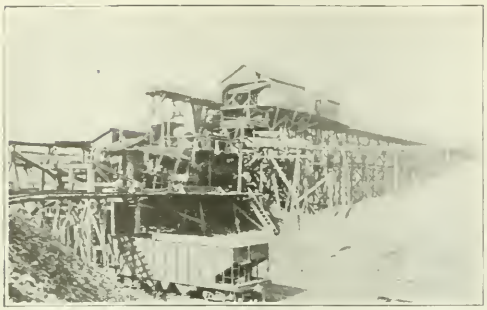
The electrochemical industry in Tennessee is in its infancy, just at present, but conditions for obtaining cheap electric power and abundant and varied supplies of raw materials are such that there are great possibilities for the development of these industries. It is the object of the present article to make a brief statement concerning present operations and indicate some of the most promising future possibilities.

Chlorine.—At Kingsport there has been noteworthy development of chemical industries of very varied type, and this is probably but a beginning of what the next few years will see at that place. Among these there is an electrolytic chlorine plant, and in connection with the Portland cement plant, potash is recovered as a by-product by the Cottrell process.

Aluminium.—At Maryville, near Knoxville, the aluminium plant consumes more electrical energy than any other one plant in the state. The raw materials for this plant come from Georgia, but deposits of bauxite are known at a number of places in Tennessee from near Chattanooga northeastward nearly to the Virginia line. There are developments of these deposits near Chattanooga and Elizabethton. The Maryville plant is planning for large hydroelectric development on the Little Tennessee River, and all indications are for a very great enlargement of their electrochemical work since when fully developed their series of dams will furnish about 400,000 horsepower.

Ferroalloys.—At Chattanooga a start has been made in the production of ferroalloys that gives much promise for future expansion. Aside from silica, which may be had in unlimited quantities for making ferrosilicon, there are pockety manganese deposits of high grade available in East Tennessee and the adjacent portion of Georgia for ferromanganese alloys, and in middle Tennessee there are large deposits of high-grade phosphate rock that would supply unlimited material for making phosphorus and ferrophosphorus. These latter substances are not as yet produced here electrochemically though a furnace in the phosphate field produces ferrophosphorus with coke as a fuel.

Undeveloped Possibilities.—Attractive possibilities for electrochemical experiment and development are furnished by the zinc ores of East Tennessee. These are now concentrated and shipped out of the state for reduction. With cheap power available and an abundance of ores, experiments in electrical smelting could be undertaken here under the most favorable circumstances. The manufacture of calcium carbide could be undertaken anywhere and abrasives could be made with equal ease. The iron ores of the region and industries dependent on iron and steel make it possible for both pig iron and steel to be produced by the electric furnace, and the demand for



BROWN IRON ORE WASHING PLANT, RUSSELLVILLE ALABAMA

such products must bring developments along these lines in the near future. Practically all of the raw materials now used in important electrochemical work are available either in the region or are accessible, as in the case of salt, in nearby regions.

Power and Labor Conditions, Etc.—Extensive development of hydroelectric power has already occurred in this region and there exist numerous other sites where large units may be developed at reasonable cost. Aside from such cheap hydroelectric power it is practicable to develop electric power very cheaply by steam in large plants located at any of the many coal mines in the Cumberland Mountain region of the state. Such plants would use slack coal delivered directly from the mine without railway haul, and could compete with hydroelectric power. The climate is favorable to continuous operation, and labor, under normal conditions, is abundant and cheap. Raw material of many other kinds is abundant and forms the basis for a varied industrial development in this region that must come in the near future.

Mineral Resources of Virginia in the Chemical Industries

By Thomas L. Watson

State Geologist and Professor of Geology, University of Virginia

Virginia produces annually more than thirty different mineral substances, the total value of which for the year 1916, the latest year for which completed statistics are available, including coke and pig iron, amounted to $30,407,414, proportioned as follows: Metallics, $2,088,492, nonmetallics, $18,154,007. The total value of coke and pig iron made in Virginia in 1916 was $10,164,915.

Among the metallics, the production includes ores of copper, gold and silver, lead and zinc, iron and manganese, and titanium; among the nonmetallics, asbestos, barite, cement, clay products, coal and its by-product coke, feldspar, gypsum, stone (granite, limestone, sandstone, and slate), lime, marl (greensand and calcareous), mica, millstones, mineral waters, pyrite and pyrrhotite, quartz, salt, sand and gravel, talc and soapstone, etc.

Some of these have been worked since early colonial days, especially coal, iron ores, and brick clays, while others are of more recent development, and all are capable of further greater expansion and production. Still others of scarcely less importance await development. Only a few of the more important raw mineral materials found in Virginia in commercial quantity and of value in the chemical and metallurgical industries can be mentioned in the space allotted.

Fuels.—The mineral fuel resources of Virginia are coal and its by-product coke, oil and gas not yet having been found in commercial quantity. The principal coal-producing territory of the State is in southwest Virginia and comprises approximately 1,550 square miles, including the whole or a part of Tazewell, Buchanan, Dickenson, Wise, Lee, Russell, and Scott counties. The coals are high grade bituminous and semi-bituminous varieties of established reputation for steaming and domestic purposes and for the manufacture of a superior grade of coke for various uses. Coals of excellent quality occur and are mined in other counties of western Virginia especially Montgomery and Pulaski.

An important coal area known as the Richmond coal basin, located in the eastern margin of the Piedmont province and covering parts of several counties, is the only area of free-burning coal in the eastern portion of the United States located immediately adjacent to Tidewater. The coals of this area were the first to be mined in the United States and they represent a good grade of the bituminous variety.

Limestone.—Inexhaustible supplies of calcareous materials admirably adapted to the various uses made of such materials, are readily available and extensively quarried over many parts of the State. These include the hard rock limestone and travertine (fresh water marl) of western Virginia, especially the Great Valley province, and more restricted areas of the former in the Piedmont province; and shell or calcareous marls of the Coastal Plain or Tidewater region. The limestones of the Great Valley region range in composition from calcium-magnesium carbonate to straight calcium carbonate, and are extensively quarried and utilized for all purposes made of limestone. Already many of the more important chemical industries of the State are partly based on the readily available inexhaustible supplies of this very necessary raw material.

Iron Ores.—The commercial deposits of iron ores in Virginia are confined to the Piedmont and Appalachian regions, and include the important types limonite or brown hematite, red hematite (specular

HIGH-GRADE FULLERS EARTH 20 FEET THICK, NEAR MACON, GEORGIA

and fossil), and magnetite. Of these, brown hematite is the most extensively mined and forms the principal source of the metal. The sulphides (pyrite and pyrrhotite) are mined on a large scale for acid making, and the iron residue ("blue billy") is utilized by the blast furnaces for making pig iron. Iron carbonates are found in several localities but thus far they have not proved to be an important source of the metal.

The brown iron ores of the Appalachian region, which include the "mountain," valley or limestone, and Oriskany ores, are commercially the most important ones in Virginia. The specular hematites of the Blue Ridge province are second in importance, the Clinton fossil ores third, and the remaining types are of minor importance.

The "mountain" brown ores extend along the west slope of the Blue Ridge, including the east side of the

BED OF PURE FINELY DIVIDED SILICA 50 FEET THICK, NEAR SHEFFIELD, ALABAMA

New River-Cripple Creek district. They range in iron content from 35 to 50 per cent, and in silica content from 10 to 30 per cent, with usually high manganese and phosphorus. The valley or limestone brown ores are distributed at intervals throughout the Valley province in association with the limestone residual clays. They are usually richer than the "mountain" ores, ranging in iron content from 40 to 55 per cent and in silica content from 5 to 20 per cent, with usually less than 1 per cent of manganese and enough phosphorus to be classed as a non-Bessemer ore. The Oriskany brown ores are the most important of the iron ores mined in Virginia. The principal producing district includes the counties of Alleghany, Botecourt, and Craig. They range between 35 and 50 per cent metallic iron, and are usually high in silica and manganese, resembling in this particular the "mountain" ores. The total number of blast furnaces in operation in the State is 14, several of which are making ferromanganese.

Manganese Ores.—Virginia has always ranked as one of the important manganese-producing states in the Union. The deposits extend over a wide territory in the Piedmont and Appalachian regions and include a large number of producing localities. Stimulated by the present war conditions the production of both high-grade manganese ores and manganiferous iron ores in the State has been recently greatly increased, and the deposits are capable of further greater production. New areas have contributed to the increased production. The ores are used both in the steel and chemical trade.

Acid-making Materials.—These include vast supplies of pyrite and pyrrhotite, which for many years have given Virginia the position of first producer of pyrite among the pyrite-producing states in the United States. The most important pyrite deposits are found in the Piedmont Plateau province, and have been and are still extensively worked in Louisa and Prince William counties, and to a less degree in several other counties, especially Stafford and Buckingham. The pyrite mines in Louisa and Prince William counties are probably the largest and most extensively developed ones in the United States.

The principal occurrence of pyrrhotite in the State is the "Great Gossan Lead" of Carroll, Floyd, and Grayson counties, which forms a well-defined vein of pyrrhotite up to 100 feet in width and traced continuously on the strike for a distance of more than 20 miles. It was formerly worked on the north end at Betty Baker, and has been mined on a large scale for the past fifteen years near Monarat, in Carroll County, by the General Chemical Company and treated in their plant at Pulaski for acid-making.

Besides pyrite and pyrrhotite, other sulphide ores mined in Virginia for purposes other than their sulphur, include the zinc blende deposits of the Valley region, especially those of Wythe County, the mixed sulphides, chiefly galena and sphalerite, of Albemarle, Louisa, and Spottsylvania counties in the Piedmont province, and the copper sulphides, chalcocite and bornite, of the Virgilina district, including Halifax and Charlotte counties, Virginia, and Person and Granville counties, North Carolina.

Salt and Gypsum.—Economically important deposits of salt and gypsum occur in southwest Virginia in the valley of the North Fork of Holston River in Washington and Smyth counties. These deposits have been extensively developed by two gypsum plants, one at Plasterco, the other at North Holston, and one alkali works of the Mathieson Alkali Company at Saltville, Smyth County, which is the center of the industry. The making of salt was stopped in 1903 and from that date to the present the salt brines have been utilized exclusively for the manufacture of alkali, chiefly sodium carbonate and caustic soda.

Barite.—This mineral has been mined for many years in various parts of the State. It occurs in many counties in the Piedmont and Appalachian regions, but the industry has been confined to only a few of them. The mineral is of excellent grade and entirely adapted to the various uses made of barite, especially in the manufacture of barium products. Many of the deposits capable of greatly increasing the present production remain practically undeveloped. The present principal mining operation is the old Hewitt mine located near Evington in Campbell County.

Rutile.—The largest and most important commercial deposits of rutile in the United States occur in the Roseland district, Nelson County, from which the entire production of the mineral in this country is derived from the mines of the American Rutile Company. Other deposits of this mineral of probable economic value are found in Goochland and Hanover

counties. The principal uses of titanium include metallic alloys, such as ferrotitanium and cuprotitanium, incandescent media for lighting purposes, mordants and dyes for leather and textiles, refractory coloring material for use in ceramics and the manufacture of artificial teeth, etc.

Miscellaneous Materials.—Under this heading are listed certain mineral materials which occur in Virginia that are no less important than those described above, but because of lack of space they cannot be discussed at present. Most of these have either produced or are producing, while others capable of producing have not been developed. These include tin (cassiterite), abrasives (emery, millstones, quartz, chert, and diatomaceous earth), mica, feldspar, asbestos, mineral paints, arsenic (arsenopyrite or mispickel), graphite, zircon, etc.

In conclusion it may be stated that Virginia's enormous supplies of high grade coal, limestones, and ores of various kinds, coupled with her abundant water resources, favorable and healthful climate, and excellent railroad facilities, afford almost unparalleled opportunity for the production and manufacture of a great variety of chemical and metallurgical products.

The Mineral Resources of West Virginia Available for Chemical, Metallurgical, and Electro-Metallurgical Manufacturing

By I. C. White
State Geologist

West Virginia possesses none of the precious metals in commercial quantity. However, dame Nature has endowed this State with such an infinite wealth of the common and more useful substances that her mineral wealth probably exceeds in value any equal area in any other political division of the continent. In fuel wealth of coal, petroleum, and natural gas she stands without a rival. With a greater variety of coal than Pennsylvania, she comes next to her in production, and within less than a decade bids fair to surpass even Pennsylvania in the output of bituminous coal. Her petroleum is of the highest grade produced anywhere in the world and although the industry began nearly 60 years ago her oil and gas wells still yield 8 to 9 million barrels of white-sand oil annually along with over 300 billion cubic feet of natural gas, practically two-fifths of all the latter product that is marketed in the entire United States, while the casing-head gasoline, and carbon black production (this last industry having originated in West Virginia) are of very great extent.

In the variety of bituminous coals, West Virginia stands unique—Steam, Domestic, Gas, Coking, High Volatile, Low Volatile or Smokeless, Splint, "Block," Cannel, oil shales being available in the several districts of the Commonwealth.

Location of the Several Varieties of Coal

The celebrated Pittsburgh coal bed, probably the most valuable single fuel deposit in the world, ideal for steam and general fuel, unexcelled for gas and coke (being the same bed as the one which furnishes the Connellsville coke for Pittsburgh's great iron and steel industries), underlies approximately 1,300,000 acres, largely in the northern half of the state. Under the principal portion of this vast area, this coal would average a recoverable thickness of six feet, or say 10,000 net tons to the acre, thus totaling 10 billion tons of commercial coal for this one seam.

This Pittsburgh coal is very rich in by-products as may be judged from the following average composition of the coal at 51 mines in the counties of Monongalia, Marion, Harrison, Taylor, and Barbour Counties, as determined by Mr. Frank Haas, Consulting Engineer and Chemist for the Consolidation Coal Company:

	Per Cent.
Moisture	1.43
Volatile matter	37.47
Fixed carbon	53.83
Ash	7.27
Total	100.00
Sulphur	2.59
B.t.u., per pound	14,014

A ton of Pittsburgh coal from the mines now owned by the Jamison Coal and Coke Company at Underwood, Marion County, West Virginia, and tested by the New England Gas and Coke Company, of Boston, Mass., gave the following by-products:

Ammonia	22 pounds
Coal tar	10 gallons
Surplus by-product gas	6,000 cubic feet
Coke	1,600 pounds

In addition to this great Pittsburgh seam in the northern half of West Virginia are two other principal coal beds; viz, the Upper Freeport Coal, 600 feet below the Pittsburgh bed, and the Lower Kittanning, the latter coming 175 to 200 feet lower. In the northern Panhandle, or Ohio, Brooke, and Hancock Counties, as also northern Wetzel, there is also a large area underlain by the Lower Freeport Coal, 50 feet below the Upper Freeport bed. This bed is 4 to 6 feet in thickness, and makes an excellent coke either in beehive or by-product ovens. It will form a great reserve of coal for the Wheeling and Ohio Valley manufacturing industries for many miles southward long after the great Pittsburgh seam lying 600 feet higher has been exhausted.

The Upper Freeport Coal of Monongalia, Preston, and adjoining counties makes an excellent coke, and is especially valuable for mixing with low-volatile coals for coking in by-product ovens, since this coal contracts in passing into coke, while some other coals swell up and thus tend to disrupt the expensive ovens. The average analysis of 1500 samples of this Upper Freeport Coal from Preston and Monongalia Counties gave the following results:

	Per Cent.
Moisture	1.60
Volatile matter	27.80
Fixed carbon	63.04
Ash	7.56
Total	100.00
Sulphur	0.99

The average analyses of 925 samples of coke from the same region gave the following:

	Per Cent.
Moisture	0.80
Fixed carbon	86.54
Ash	12.66
Total	100.00
Sulphur	0.98

A by-product test on a car-load of this coal, made at Indianapolis, Indiana, by the Citizens Gas Company of

that city, in March, 1912, yielded the following results:

		Pounds
Weight of dry coal charged		14,460
Dry coke produced, large pieces	74 35 per cent	10,752
Dry coke produced, small pieces	0 93 per cent	135
Breeze produced	1 58 per cent	229
Total	76 86 per cent	11,116
Yield of tar, 4 36 per cent of dry coal		630½
Sulphate of ammonium, 1 21 per cent of dry coal		173

The splendid quality and wonderful variety of coals in the southwestern half of West Virginia along the lines of the Coal and Coke Railway, the Kanawha and Michigan, Chesapeake and Ohio, Virginian, and Norfolk and Western Railways, are so well known in the markets of the country that they scarcely need any special description. These coals are described in detail and published along with hundreds of analyses in the reports and maps of the West Virginia Geological Survey, a list of which briefly describing each publication can be obtained from the offices of the Survey, Morgantown, West Virginia.

Some of these "Kanawha Splint" coals, like the Coalburg and Winifrede, contain such a small quantity of iron in the ash that the latter is practically white and hence these coals can be used to great advantage as a fuel in the manufacture of snow-white Portland cement. The fusing point of their ash is above 3000° F

The New River and Pocahontas Coals are generally known to the trade as "smokeless" and are specially valuable for steam and bunkering purposes for use on freight and battle-ships, and they make splendid coke.

The total coal deposits of the several counties of the State as figured from the detailed surveys of the several counties already made and from close estimates on the few (7) remaining ones not reported upon aggreate a net tonnage of 105 billion, of which at least 83 billion net tons may be regarded as recoverable coal. The total quantity of coal already mined during the 60-odd years of West Virginia's coal mining history totals only about one billion net tons, or less than 1 per cent of her total deposits. Hence the West Virginia factories and those to be located therein hereafter can be assured of a practically unlimited and cheap fuel supply extending into a far distant future.

Limestone in large deposits of commercial value is confined to the eastern counties of the State, like Jefferson, Berkeley, Morgan, Hampshire, Mineral, Hardy, Pendleton, Pocahontas, Greenbrier, Monroe, and Mercer, although thick deposits occur in Monongalia, Preston, Tucker, Grant, Randolph, and Barbour, belonging to the Mountain or Greenbrier Group. Up to this time the only large quarry operations on the limestones of the State, except for railway ballast and one cement factory at Manheim in Preston County, are located in Jefferson and Berkeley Counties, where vast quantities of the very highest grade of limestone used in the manufacture of plastering lime, hydrated lime, Portland cement, and for flux in iron and glass furnaces, crop out along the Baltimore and Ohio, Norfolk and Western, and Western Maryland, and other railway lines. These limestones are fully described and analyses given in the Survey volume on Jefferson, Berkeley, and Morgan Counties, along with the other minerals of that area including vast deposits of very pure Dolomite.

Iron Ores, of which West Virginia has 200 to 300 million tons, principally in the counties of Hampshire, Hardy, Mineral, Grant, Pendleton, Pocahontas, Greenbrier, and Monroe, are described in Volume IV of the West Virginia Geological Survey, along with the enormous resources of the State in glass-sand, and saline brines, many analyses of all of which are given therein.

Saline Brines along the Ohio River Valley to be obtained by boring to depths of 1000 to 1200 feet anywhere between Moundsville and Kenova, and along any of the tributaries of the Ohio, like the Little Kanawha, Great Kanawha, Guyandot, Twelvepole, and Big Sandy Rivers, are especially rich in other minerals besides common salt; viz., bromine, and calcium and magnesium chlorides, etc. These brines have been operated continuously in Kanawha County for more than 100 years, and for nearly that long in Mason County on the Ohio River, and as a basis for large chemical industries where good coal exists in the immediate hills, or else can be brought by cheap rail or waterborne freights to the immediate doors of the factories, no more attractive sites could be found in the entire country. The composition of these brines is shown by the following analyses reproduced from Volume IV, West Virginia Geological Survey, page 332:

	Parts in 1,000 Parts by Weight
Sodium chloride	60 1762
Sodium bromide	0 2238
Sodium iodide	0 00098
Sodium nitrate	0 00000
Sodium arsenite	0 0000097
Sodium borate	Small amount, not estimated
Potassium chloride	0 5700
Lithium chloride	0 1010
Ammonium chloride	0 0787
Barium chloride (= 46.14 grains per gallon)	0 7447
Strontium chloride	0 2013
Calcium chloride	15 0103
Magnesium chloride	4 9692
Calcium bicarbonate	0 2661
Ferrous bicarbonate	0 0822
Manganous bicarbonate	0 0076
Calcium phosphate	0 0005
Aluminum	Trace
Silica	0 0040
	83 3456
Specific gravity at 15 5° C.	1 0628

The Clay industry of West Virginia is only in its infancy, having been confined principally to the counties of Ohio, Brooke, and Hancock, along the Ohio River front, where are situated some very large sewer-pipe, brick, china, pottery, and other clay-working industries. Good clays and shales for the manufacture of common, vitrified, and pressed brick, however, are abundant in nearly every county of the State, and large clay-working industries are possible in the immediate vicinity of good gas territory, and outcropping coal beds. The succesful potteries at Cameron, Mannington, etc., and the vitrified products made at Parkersburg, Huntington, Weston, and elsewhere in West Virginia, as well as the large and successful brick plants at Charleston, Huntington, Thornton, Hammond, Morgantown, and elsewhere in the State, demonstrate the wide field open for these and kindred investments where the raw materials, like glass-sands, limestones, iron ores, clays, saline brines, etc., are in close physical association with vast deposits of coal and natural gas.

Some Experiments on the Extraction of Radium from American Pitchblende Ores by Chlorination

By Mrs. RAY CABLE and HERMAN SCHLUNDT

THE uraninite in the pitchblende ores of Gilpin County, Colorado, occurs very intimately associated with iron pyrites. Apparently no satisfactory method of separating the uranium minerals from the pyrites by mechanical methods has been developed. Concentration of the ore by the ordinary mill operations results in several products ranging in content of uranium oxide, U_3O_8, from 1 per cent to 25 per cent. The final blending gives three grades: high-grade, containing upwards of 16 per cent U_3O_8; medium-grade, averaging about 4 per cent; and low-grade containing less than 2 per cent U_3O_8. The main body of all grades however is iron pyrites.

The extraction of radium from these ores has been carried out successfully on a commercial scale by methods developed in the U. S. Bureau of Mines. During the summer of 1916 one of us assisted for a time in the laboratory experiments conducted in the Mining Experiment Station of the U. S. Bureau of Mines at Golden, Col., preliminary to plant operations. We were thus brought face to face with some new problems in radium extraction from an ore differing fundamentally from the European pitchblendes in its distinctively high content of sulphide minerals. Subsequently we continued our investigations on these ores in the chemical laboratory of the University of Missouri. The experimental results here presented summarize the results obtained by a new method of extracting radium by direct chlorination of the ore. We are indebted to Dr. R. B. Moore, Superintendent of the Golden Station for the samples of ore used in these experiments.

The Reaction

When the ore is heated in an atmosphere of chlorine, interaction takes place readily. The principal products of the reaction are sulphur monochloride, S_2Cl_2, and chlorides of the metals present. The reaction of chlorine with iron pyrites takes place mainly according to the equation,

$$2FeS_2 + 5Cl_2 = 2FeCl_3 + 2S_2Cl_2$$

and is an example of one of the general methods of preparing sulphur monochloride. By conducting the reaction in a stream of chlorine gas the chloride of iron together with chlorides of uranium appear as a crystalline deposit in the cooler parts of the apparatus, while the more volatile product, sulphur monochloride, can be separated as a gas which is easily condensed and collected in a receiver. Chlorination probably converts the radium into chloride, which, contrary to our expectations, is also carried forward in the current of chlorides, a relatively small fraction only remaining with the unattacked constituents of the ore.

Upon the addition of water to the residue and anhydrous chlorides of the metal a very vigorous interaction occurs. The radium compounds for the most part remain in solution. After filtering off the small insoluble residue, the radium can be precipitated very nearly quantitatively as radium-barium sulphates by adding to the filtrate a little barium chloride solution and its equivalent of sulphuric acid. The addition of sulphate ions to precipitate the radium-barium sulphates is, as a rule, not necessary inasmuch as a small quantity of sulphates is generally produced in the course of the chlorination. The reason for the radium not precipitating in the presence of sulphates when the chlorides are treated with water, we are inclined to attribute to the lack of sufficient barium in the ore. Recent determinations of the solubility of pure radium sulphate conducted by Lind, Underwood, and Whittemore[1] in the Golden Station of the U. S. Bureau of Mines have fixed the solubility of radium sulphate in water as approximately a hundredfold less than that of barium sulphate. Nevertheless the minute quantities of radium in the solutions here under consideration still lie below the solubility product of radium sulphate. However when radium sulphate is precipitated together with a large excess of barium sulphate the solubility of radium sulphate is far below the actual solubility of radium sulphate. Hence precipitation of barium sulphate in quantity a hundredfold or more the solubility of barium sulphate in the solution results also in a practically quantitative precipitation of the radium.

The Ore Samples

Experiments were conducted with the three grades of ore designated respectively low, medium, and high-grade. The radium content of each grade was determined quantitatively by separating the emanation from weighed samples, and measuring the ionization current product by it in standardized electroscopes[2]. The percentage of uranium was computed by multiplying its radium content by the established constant, 3×10^6, for the ratio of uranium to radium in primary uranium minerals. The analytical results thus obtained appear in the tabulated summary given herewith. The percentage of uranium in the high-grade ore was also determined by chemical analysis in the laboratory of the Bureau of Mines and found to be 17.58 per cent U_3O_8, a value in close agreement with the uranium oxide equivalent of 17.45 per cent calculated from the radium content. Since some emanation is continuously liberated from the ore under ordinary conditions of temperature and pressure it is necessary in making radium determinations on samples not previously sealed until equilibrium has been

[1] Jour. Amer. Chem. Soc., XL. 3, March, 1918

[2] For a description of the method and the apparatus used see, Lind, "Practical Methods for the Determination of Radium," Jour. Ind. and Eng. Chem. 7, 406 and 1024 (1915). See also Schlundt and Moore, Jour. Phys. Chem. 9, 320, (1905)

attained to determine the emanating power on another sample. We found that the emanation lost in the cold ranged from 6 to 9 per cent of the total in the different grades. The values for the radium content given in the table are, of course, based upon the equilibrium quantity of emanation.

In making the radium determinations the emanation was separated by dissolving suitable quantities of the finely ground ore in 40-per cent nitric acid and collecting the gaseous products in a gas burette over a hot solution of sodium hydroxide. The interaction of hot nitric acid with the sulphides of the ore produces several oxides of nitrogen, one of which, nitric oxide, is absorbed only very sparingly by the alkaline solution. As a result the volume of gas in determinations where samples of about a gram of ore were required was found to exceed the capacity of our gas burettes. This difficulty in the usual procedure may be overcome either by largely displacing the air in the reaction flask with oxygen before introducing the nitric acid, or by admitting oxygen into the burette from time to time during the progress of the reaction. Oxygen converts nitric oxide into nitrogen peroxide, NO_2, which is readily absorbed in the solution of lye.

The Experiments

For chlorination, the ore in charges of 30 to 35 grams was spread out over about one-third the length of a 1½-meter piece of hard-glass combustion-tubing of fully 2 cm. diameter, fitted at both ends with one-hole rubber stoppers. The ore charge was heated in a long combustion furnace of the type usually employed for combustion analysis of organic compounds. On the one hand the tube was connected with a tank of liquid chlorine, and on the other with a condenser and receiver. A wash-bottle containing sulphuric acid was placed in the train next to the chlorine tank, and this was followed by a T-tube dipping into mercury which served as a vent for the escape of chlorine in case the products of the reaction ever clogged up the outlet end of the tube. A plug of glass wool was inserted near the outlet end of the tube to stop small amounts of metallic chlorides that are apt to be swept along by the vapors of sulphur monochloride when chlorination is rapid. In the early experiments the ore charge was placed in several porcelain boats, but after finding that only a small fraction of the radium remained with the unattacked residue the boats were no longer used.

The chlorination was conducted by heating moderately at first with a slow stream of chlorine passing until rapid reaction starts which occurs before low redness is reached. The supply of chlorine was then materially increased and the temperature gradually raised to low redness. The metallic chlorides formed are deposited along the tube beyond the heated portion and sulphur monochloride passes on to the condenser if the cooler part of the tube is kept at a temperature above 137°, the boiling point of the monochloride.

Chlorination of the low-grade ore was at first carried out with samples ground to pass through an 80-mesh sieve, but when it was found that this degree of comminution is not necessary for complete chlorination, ore of 20-mesh was used in the subsequent experiments with medium and high-grade ores. Several of the chlorinations lasted three to five hours but in most of the experiments the flow of chlorine was so regulated that a charge of 35 grams was completely chlorinated within an hour. Turning the tube a little with an occasional tapping saves time.

When the tube had cooled it was taken from the furnace and the contents washed out with water or very dilute hydrochloric acid. After boiling, the insoluble residue, the tailing was filtered off, washed, ignited and weighed. The filtrates were again heated to boiling and radium precipitated by adding a few cc. of a 10 per cent solution of barium chloride and an excess of sulphuric acid. Three or four days after precipitation the sulphates were filtered off, ignited, weighed, and finally assayed for radium. The liquors were diluted to 500 cc. and samples of 200 cc. were boiled and sealed up for quantitative determinations of radium remaining in solution.

Complete duplicate experiments were conducted with each grade of ore. The recovery of radium in the sulphates, and the losses of radium in the tailings and liquors were determined by the emanation method. Carefully standardized electroscopes[3] of the interchangeable type[4] designed by Dr. Lind of the Bureau of Mines were used in the radium determinations, and use was made of the apparatus for boiling off and transferring the emanation described by the same author. Small samples (20 mg.) of the radium bearing sulphates were fused with mixed carbonates of sodium and potassium in small platinum boats which were then stored in sealed tubes for definite periods and finally decomposed with 1:1 nitric acid in an apparatus for collecting the emanation quantitatively. For determinations of radium in the tailing samples, about half the quantity of insoluble residue from 35 grams of ore was fused with mixed carbonates in platinum crucibles, the melt poured out into an iron mortar, powdered and then sealed in thin glass bulbs. After several days of storage the accumulated emanation was separated by decomposition with nitric acid. Details of the procedure and calculation of the results are given in some of the references cited.

The Results

The experimental results are summarized in the Table I.

The recovery of radium is satisfactory for each grade of ore, and the radium content of the sulphates lies well within the limit required for further concentration by fractional crystallization after conversion of the sulphates into chlorides. The concentration ratios were computed by dividing the figure for the concentration of radium in the sulphates by the radium content of the grade of ore from which the sulphates were recovered. The radium losses given for the liquors are probably too low inasmuch as our method of testing simply accounts for the radium actually in solution, and does not include possible traces of radium carried in suspension. We are, therefore, inclined to assign the percentages of radium unaccounted for at least in large part to this avenue of loss because a second

[3] Leaming, Schlundt, and Underwood, Trans. Am. Electrochem Soc., 30, 375, (1916)

[4] Loc. Cit.

precipitation of barium sulphate in the liquors invariably gave a "second" sulphate of higher radium content than the loss found in the liquors by our method of testing. We are convinced that the loss of radium in the sulphur monochloride is negligible. In one experiment the residue left upon evaporation of the chloride when tested by the ordinary alpha-ray method showed no activity whatever.

It would be interesting to ascertain whether the radium in the deposit of metallic chlorides can be further concentrated by volatilizing the anhydrous chlorides again. Perhaps the radium would then remain for the most part in the non-volatile residue.

We hope to extend the investigations in the near future to larger samples of ore.

A few chlorination experiments with carnotite ore did not give results of promise for a method of extracting radium.

The chlorination experiments with low-grade ore represent one phase of a more extended investigation on the extraction of radium from pitchblende ores to be submitted by Mrs. J. Ray Cable as a thesis in partial fulfillment of the requirements for the degree of Master of Arts, University of Missouri.

Chemical Laboratory, University of Missouri

TABLE I. SUMMARY OF RESULTS

	Grade of Ore	Low	Medium	High
2	Radium content of ore, parts per billion	3.43	8.312	49.27
3	Uranium content of ore, expressed as U_3O_8	1.20%	2.92%	17.45%
4	Weight of ore used	32.0 g.	35.0 g.	35.0 g.
5	Weight of tailings	3.30 g. = 10.32%	0.795 g. = 2.27%	3.53 g. = 10.09%
6	Total radium in ore sample	109.8×10^{-9} g.	290.9×10^{-9} g.	$1,724.5 \times 10^{-9}$ g.
7	Weight of sulphates recovered	0.0938 g.	0.237 g.	0.635 g.
8	Radium recovered in sulphates	102.5×10^{-9} g.	267.1×10^{-9} g.	$1,615 \times 10^{-9}$
9	Radium recovered in sulphates	93.34%	91.78%	93.68%
10	Concentration of radium in sulphates—parts per billion	1,084	1,127	2,543
11	Concentration ratio	316:1	135:1	51.6:1
12	Radium losses:			
	(a) In tailings—emanation method	1.954×10^{-9} g. = 1.74%	4.36×10^{-9} g. = 1.53%	56.6×10^{-9} g. = 3.29%
	(b) In liquors—emanation method	4.23×10^{-10} g. = 0.34%	1.49×10^{-9} g. = 0.51%	4.43×10^{-9} g. = 0.26%
13	Radium unaccounted for	4.58%	6.18%	2.77%

Hydro-Electric Power in Relation to Industry*

By J. A. JOHNSON

THIS country is undoubtedly on the eve of a great development of its hydro-electric power resources. If it isn't, it ought to be. The time is ripe for it and conditions demand it. The nation is facing the gravest crisis in its history, not only in a military sense but in a political and economic sense. Our immediate problem of course is to win the war, but after the war is over there will be other problems to solve. Labor, for instance, has undoubtedly got to be reckoned with, and there will be immense problems involving the control of industry by the government and the attitude and spirit in which that control is to be exercised. Are we to go in for government ownership and operation of industry, or are we not? And if so, to what extent and how?

These and many other questions are demanding answers, and it therefore seemed to me that it would be far more profitable and useful for us to discuss this phase of the problem, than merely to be listening to a more or less instructive address on power-plant design. I therefore concluded that I would try to discuss the subject from the standpoint of the utilization of the power, that is, the relation of hydro-electric power to industry.

Essential Factors in Industry

In any industrial or manufacturing undertaking there would seem to be about five major factors which largely determine its location and its success or failure after it is located. These are—

1.—Raw material
2.—Transportation
3.—Power
4.—Labor
5.—Market

Raw Materials must be transported to the plant, then transformed by means of power and labor into the finished product and again transported to the market. We are to consider the relation of the factor of power, principally hydro-electric power, to the other four, raw materials, transportation, labor and market.

Industries may be broadly divided into two general classes:

1.—Those in which the cost of power is a large part of the cost of the product.
2.—Those in which the cost of power represents only a small percentage of the cost of the product.

Power developments may also be broadly divided into two general classes:

1.—Those having a continuous steady supply of water, such as Niagara Falls, and which are therefore capable of delivering power continuously;—and
2.—Those having a more or less variable supply of water, and which are therefore incapable of supplying continuous power.

In the first class of industries are those using electric power in large quantities for electrochemical and electrometallurgical processes. In such industries a low power-cost is usually essential to meet competition in the finished product from other more favorable sources. Such industries usually work with continuous processes, or at least processes requiring continuity for highest efficiency, consequently require power continuously, and therefore necessarily seek power sources of the first class, which can continuously supply the power continuously needed.

In the second class are those industries using power for mechanical purposes, that is, for driving machinery. Such industries usually operate for eight to ten hours per day only, hence have a low load factor, that is, they require their power only intermittently. Such industries therefore are adapted to utilize hydro-electric power sources of the second class, which have an inherently low "supply factor," as it might be called.

Now, this country is going ahead and developing its

*A paper read before *The Engineering Society of Buffalo* on March 13th, 1918.

hydro-electric powers. What is it going to do with them after they are developed? How are they going to be used? Are continuous powers to be frittered away and wasted in losses in long transmission lines and in supplying the intermittent demands of intermittent industries, while perhaps continuous industries are left to operate inefficiently on the "leavings" in the form of intermittent powers and the intermittent off-peak or secondary capacity of the continuous developments which have been primarily used for intermittent service? Or, is an intelligent effort going to be made so to co-ordinate the requirements of industry with the characteristics of the power developments that each development will be utilized in the most efficient manner?

If the problem were as simple as it sounds, it would be a fairly easy matter, but unfortunately or otherwise, it is not so simple. Hydro-electric developments are extremely diverse in character. They range all the way from plants having a "supply factor" of 100%, i. e. capable of delivering their full output continuously to those whose "supply factor" is perhaps no greater than 10% or even less. Furthermore, the time factor enters into the problem. Some plants, having practically no storage, and located on variable streams, are obliged to deliver their power practically as the water flows. They are, therefore, subject to great seasonal variations, and other irregularities of flow, which place a limit upon the extent to which they can be developed economically. In order to utilize such developments to the best advantage, they have to be supplemented by some other source of power, such as steam plants, in order that the industries using power may be assured of a reasonably constant power supply throughout the year. In cases where the cost of development is not too great, this plan is feasible and is often employed.

Other plants there are, which can be developed with a small amount of water storage capacity. Such plants can utilize a slightly larger proportion of the total flow and can themselves take care of load fluctuations of short duration, such as the demands of eight to ten hour customers, through their ability to store up water during the night for use during the day. There are already hundreds, perhaps thousands of such powers developed, often for the driving direct by water wheel of small manufacturing plants. Many a small town is built up around just such a power. There are doubtless thousands of others, many of them in inaccessible locations, which might be developed and the power transmitted to the nearest towns there to be used for similar purposes. Such powers can probably best be developed in connection with larger developments in their neighborhoods, and probably will be developed to a greater and greater extent through the application of the automatic generating station which has now been brought out by one of the largest electric manufacturing companies. This, by the way, is an extremely interesting innovation. Such stations require no attendance except periodically, and are cut on and off the circuit automatically through the agency of automatic switches operated by the water level in the forebay. In my opinion such stations are destined to play an important part in the development and utilization of our small water powers, of which we have a vast number, aggregating a very large amount of power.

Still other powers can be provided with vast storage reservoirs capable of storing up a large proportion of the total flow of the stream for months at a time, thereby enabling the power plant to operate nearly or quite continuously throughout the year. Sometimes a whole river can be so controlled and regulated by means of large reservoirs at the head waters which can be created by storage dams, thereby enabling a whole series of power plants located at different points on the river to be operated continuously, all using the same water as it flows down toward the sea. In this way the enormous quantities of water liberated by the melting snows of spring can be stored for use during the dry summer months and the fall rains for use during the frozen winter months.

Cost of Developing Hydro-Electric Power

Water powers also vary greatly as to their costs per horsepower developed. Nothing is more false than the popular belief that water power is necessarily cheap because water is a free gift of nature.

The cost of developing a hydro-electric power proposition may be anywhere from about $40.00 to $200.00 per horsepower. Developments costing less than this minimum are few and far between, and above about this maximum they cease to be commercially practicable under present conditions.

Hydro-electric developments also vary greatly in location. Some are located in the midst of densely populated districts, others more distant from civilization, and still others far away in the inaccessible wilderness. Victoria Falls, South Africa, one of the largest if not the largest single possible source of power in the world, is located so far from all human activity that it has thus far been impracticable to develop it. On the other hand, our own Niagara, located though it is in the very midst of the most thickly populated portion of the United States and Canada, is as yet only developed to a fraction of its possible capacity. In fact, water powers vary greatly in location with respect to all four of the factors of industry, raw material, transportation, labor and market.

It is clear then that hydro-electric powers are of infinite variety as to characteristics, cost and location. The problem therefore of co-relating industries with hydro-electric power is a complicated one.

Nevertheless, if our natural resources are to be conserved to the greatest extent, it is necessary, not only that our water powers shall be developed and put to work, but also that each power shall be put at the work it is best suited to perform. This applies not only to water power, but to steam power as well. It is an economic waste to use low-cost power for purposes for which higher-cost power would serve equally as well in those cases where the cost of the product would not be materially increased thereby.

It would seem worth while, therefore, to inquire to what uses the several types of hydro-electric developments should be put for the greatest economic benefit. Let us then consider briefly the several types of hydro-electric powers as related to industrial use.

Types of Hydro-Electric Development

First, consider a power located in the wilderness at a considerable distance from all four of the factors of industry. How is it to be utilized? Obviously only in

exceptional cases can the industry go to such a power, the exceptions being when some one or more of these factors can conveniently and cheaply be brought to the power along with the industry. In most cases such a power can only be utilized at all by transmitting it to the neighborhood of a sufficient number of the industrial factors to enable it to be utilized economically. Such transmission costs money, introduces power losses and adds to the cost of the power, and the power so transmitted must be able to compete with power from other sources such as coal, gas or oil. Power which has been transmitted any great distance is usually too greatly increased in cost thereby for use by the continuous class of industries mentioned, hence a market for it must be found among public utilities and industries of the intermittent class to whom the cost of power is not of vital moment.

As an example of a power of this general character I would mention the Salmon River Power Co. Such powers are often unsuited to the use of industries of the continuous class not only on account of cost, but also owing to their inherently low "supply factor" characteristic. The Salmon River Co. is such a one, as it is upon a stream of very variable flow, and could be developed at all only by resort to storage. This plant is located about forty miles north of Syracuse, near the little town of Altmar, N. Y., and as you doubtless all know, is now a part of the system of the Niagara, Lockport & Ontario Power Co., supplying a general industrial and public utility load, a service to which it is eminently well suited, and about the only type of industry which is suited to it.

There are many such powers yet undeveloped, for the reason that they are so far from civilization that they cannot compete in the market with power from coal, but it is quite possible to conceive that government control may, by regulation of the uses to which coal and other consumable resources may be put, force the development of such powers for use by public service and manufacturing industries to which the cost will not constitute an excessive burden if the competition of coal is eliminated. The development of such powers would, in the natural course of events, await the increase in the price of coal, but if the government fixes arbitrarily the price of coal, it may also determine to what uses it may be put, under which conditions inaccessible powers could and should be developed. The coal would thereby be conserved for those uses for which electric power is too costly.

In view of the present situation it does not seem at all improbable that such a situation may come about in the not far distant future.

Now let us consider the power which is located near one or more of the four factors of industry. Such powers may be and are of infinite variety as to their size and characteristics, and also as to the particular factor or factors to which they are accessible.

Take for instance the Shawinigan Water & Power Company at Shawinigan Falls, Quebec. Located about midway between Montreal and Quebec City, on the end of a branch of the "Great Northern Railway," it had, at the time of its first development, neither raw material, transportation, nor nearby market. Montreal and Quebec would appear to offer the best outlets for the power, and transmission lines were built to the former, but the location, only about twenty miles from the St. Lawrence River, and the abundant supply of cheap labor from the French Canadian population, soon overcame the apparent drawbacks, and large electrochemical industries proceeded to locate close to the development. Railroads were built to the St. Lawrence at Three Rivers, thus supplying the two factors of cheap transportation and labor, which, coupled with cheap power, were sufficient to overcome the lack of raw materials and a nearby market. Shawinigan Falls is now a thriving industrial city, and the power of the St. Maurice River is being used at the source in the manufacture of the manifold electrochemical products which have become so essential to modern civilization.

Consider also Niagara Falls. Here is a power almost unlimited in quantity, absolutely continuous in character, fairly cheap to produce, with abundant transportation and labor immediately at hand, and practically in the midst of the market for its products. How should that power be used in order to produce the greatest benefit to the nation and to mankind? Obviously it is designed by nature for use in those industries which require continuous power, that is, for electrochemical and electrometallurgical processes. In what way can a kilowatt-hour of Niagara power be used for the greatest good? Is it desirable that it be carried to some distant point such as Windsor or Sarnia, with a loss of 15 or 20 per cent, and there dissipated in wasteful and extravagant lighting under what amounts to a government subsidy? Should it even be sent to Toronto to be used in the pumping of water at a cost greater than could be accomplished by steam power? Is it even desirable that this power be sold for public service purposes near at hand at prices so low as to promote carelessness and wasteful extravagance? Would it not be better to distribute this power for such purposes only to such distances as can be done economically, in proper competition with other sources, and to sell it only at such prices as will promote economical use, and to utilize the greater part of it at the source in the manufacture of abrasives, ferrosilicon, fertilizers and a thousand and one other products which are being made at Niagara Falls, N. Y., and which are of such importance in the modern industrial world? Modern civilization is dependent on these things. Take ferrosilicon, artificial abrasives, and aluminium away from the automobile industry, for instance, and what would be the result? Quantity production, as we now know it, would be an impossibility. We have it on authority that weights would be increased over 80%, production would be reduced by about 80%, and prices would go out of sight. The same would be true in greater or less extent all down the line. Practically everything we use would be affected, even to our food, into which these things enter in the form of farm machinery, tractors, fertilizers, etc.

Results of Failure to Co-ordinate Power and Industry

The fallacy of the thing has been made fairly obvious by the demands of this war. What has happened? Why, people have been exhorted to reduce their lighting in order that industries making munitions, principally ferrosilicon and similar products, might have the power. Street lights have been slashed right and left for the same purpose. Streets have been left in darkness till

late at night, whole sections of cities have been cut off from their lighting circuits in the day time and deprived of the use of their electric irons, toasters, vacuum cleaners, etc., for hours at a time in order that electrochemical industries might have the power. On the one hand people are being exhorted to use power, to buy electric power-consuming devices, and on the other are being deprived of the power that they have been exhorted to use. To be sure, this is a war condition, but war or peace, is the principle any different? Will not the same conditions exist ultimately under peace conditions?

Well, how are we going to accomplish this co-ordination of power and industry? Shall we depend on public ownership to do it? Public ownership is doing just the opposite. Most of the economic crimes which have been committed in connection with hydro-electric power have been committed by public ownership.

Just a word as to public ownership. Its slogan is "Power at Cost." Well, what is "cost"? It is likely to be something quite different under public ownership from what it is under private ownership, but you're not supposed to know that. You are supposed to be hypnotized by the thought of getting power at cost and made extremely joyful at the prospect of depriving some criminal corporation of its ill gotten gains. Well, what happens?

In a private corporation no project is entered into without thorough study and investigation of plans, methods, costs, probable earnings, etc., etc. The success or failure of the undertaking depends on the accuracy of these estimates, as there is always competition to be met.

Under public ownership and the "power-at-cost" principle, what happens? Well, it's "power at *cost*." The people have got to foot the bill anyhow, so why worry about the cost and why go to all the labor and pains to make careful estimates and well considered plans? Rough estimates will do—all they are for anyhow is to serve as a basis for an appropriation. Make them as low as possible so as to make it look attractive, because after the work is started it will have to be finished anyhow, whatever it costs. And, as to plans, why bother about extensive investigations; probably the different schemes will not differ much in cost anyhow, and as the cost has got to be paid, whatever it is, why go to all that unnecessary work. It is very easy to explain to a gullible public that the high cost was due to the increase in the price of materials and labor or something else. The result is likely to be "Power at Cost" with the accent on the *cost*. The legitimate profit which the private corporation would make by careful and efficient management is probably more than swallowed up in the wasteful and extravagant methods of the publicly owned undertaking, but the public doesn't know that, so is perfectly happy—for a while.

As a matter of fact it is well known that long distance power transmission enterprises have not been particularly successful financially even under private ownership, such profits as have been made being small even under the most economical management possible. That any substantial reduction in actual cost to the consumer in such enterprises can be effected by public ownership is extremely unlikely.

There are ways, however, in which the illusion can be kept up. For instance, in a certain city where public ownership prevails, power is sold to lighting customers at two cents per kw.-hr. up to a certain point, with a reduction to one cent for all excess. The waterworks department of this same city is required, against its own desire, to use large amounts of electric power for pumping, and for that service is charged the equivalent of 2⅝ cents per kw.-hr. Also this same city has installed an extensive and extravagant street lighting system which also forms a very convenient dumping ground for the excess power costs. The tax rate of this city this year was about thirty mills, of which one mill or about 3 per cent was to pay for deficits on its publicly owned utilities.

A second objection to government ownership—unless it is complete, an absolute monopoly—is its injustice. All public service corporations are subject to government regulation whenever the government chooses to exercise it. For the same government to enter into competition with the same corporations which it has the power to regulate, is manifestly unjust and leads to all sorts of abuses for which there is no redress.

It is impossible to keep politics out of publicly owned utility, or to keep the utility out of politics. A power monopoly, particularly, offers too easy an opportunity for unscrupulous politicians to establish and maintain undue political, social and economic power over a large population. With such an instrument being used for political purposes its policies, purposes and methods take on a political complexion, and even problems which should belong solely to the realms of engineering and economics are decided by political considerations.

For instance, the transmission of Niagara power to Sarnia, a distance of nearly 200 miles, where they had a perfectly good, brand-new, up-to-date steam-turbine electric plant, which was deliberately put out of business thereby, can hardly be justified on either engineering or economic grounds.

Another objection to public ownership is its apparent inability to keep ahead of the game. It is always scurrying to keep up with the procession. It falls into the never ending circle of scurrying on account of lack of foresight, and lack of foresight on account of being always scurrying. Consequently it is always facing a crisis of some sort due to its failure to prepare in advance. This condition may be partly due to inferior personnel, partly to playing politics, and partly to lack of authority to spend money or ability to obtain authorization from the legislative body for the expenditure of money for future requirements; but whatever the cause, it is a condition which exists.

However, there is a strong trend toward public ownership. If we are to have it, let's go into it with our eyes open, and when we are in it, let's insist that it be open and above-board. Personally I do not think we can look to public ownership for the solution of the problems of correlating hydro-electric power and industry.

What then can be expected of private ownership? I believe private ownership has done very well. The bulk of the power generated at Niagara, on the American side, is used for the purposes nature intended. A certain amount, to be sure, is transmitted away for public utility use, but this is perfectly legitimate, as it is right and proper that enough of the power should be used in this way to supply the reasonable needs of the people within reasonable transmission distance. Also a steam

station has been built to supply further requirements in this respect. This also, in my belief, is quite as it should be. Steam power is quite suitable, and can be supplied at reasonable cost commensurate with the service rendered, for such industries and utilities as are, or will be, located at Buffalo.

Further development at Niagara should be reserved for those industries requiring large quantities of cheap continuous power for the manufacture of important—nay, indispensable—materials of industry, materials which are so vitally needed at the present time.

What, then, of the government? Is there no function which it should perform in this important matter? I believe that there is. It should see that water power is developed with reasonable economy and utilized to the best advantage. It should establish a commission on this correlation of hydro-electricpower and industry, which should make a thorough study of the water powers of the country with a view to their early and proper utilization. It should seek to bring together industries seeking power and water powers seeking customers, to the end that the water powers of the country may be put to those uses to which they are individually best adapted, and that industries may find inconsumable power sources suited to their needs. So far as water powers on the public domain are concerned, it should promote their utilization under conditions sufficiently favorable to attract capital and under such restrictions as may be necessary to guard the public interest. In all these matters it should adopt a constructive policy designed to promote in every legitimate way the proper and immediate development and utilization, under private ownership, of the country's vast water power resources.

The Possibilities for the Development of Chemical Industries in the Southern States

By RICHARD K. MEADE

ALL things in the South either begin or end with the Civil War. When Lee surrendered at Appomattox, the old South died and the new South was born. The old South was primarily an agricultural community. While here and there a Welsh, Swedish or German colony scratched the hillsides for iron ore and smelted this with charcoal in primitive furnaces, the great mass of the population was dependent on agriculture for a livelihood. There was almost no manufacturing carried on in the States comprising the Confederacy. The cotton which was raised was sent north to be woven into cloth by the looms of New England and vast other sources of raw material lay untouched.

With the fall of the Confederacy, the new South was born. The child naturally inherited some of the characteristics of the parent, but it also began to develop talents of its own, and while the South is still a great agricultural community, producing as it does more than half of the total value of the farm products of the country, its mineral and other resources are rapidly being developed and turned into manufactured articles in Southern plants and workshops.

The new South has passed through all of the phases of childhood to its present well-developed manhood. The reconstruction era was its cradle period and the closing years of the eighteenth century found it just beginning to walk. Until quite recently, its young men who were technically inclined, discouraged by the few openings for the display of their skill and energies in the states of their birth, emigrated to the West and opened up mines or came north and dug tunnels under the Hudson River or fixed nitrogen from the air at Niagara Falls.

With nearly a third of the population of the United States within the South, the total capital invested in manufacturing throughout this whole region is but little greater than that invested in such enterprises in the State of Pennsylvania alone. The six Southern states, Virginia, North Carolina, South Carolina, Georgia, Alabama and Tennessee, which are richest in mineral resources, have less capital invested in manufacturing than Massachusetts, and yet the latter state is almost without any natural advantages in raw materials.

In considering the South, therefore, as a manufacturing center, we must view it rather as to its future possibilities than from any past performances, in spite of the fact that the growth of manufacturing in the new South during the last two decades has been rapid.

There are now manufactured in the Southern states a considerable amount of iron and all of the cement which is needed in this territory. The coal dug from Southern hillsides today is greater than that mined throughout the whole United States twenty years ago. Practically all of the phosphate rock in this country comes from the South and the oil wells of this section produce more than half of our petroleum.

At the risk of boring the reader by enumerating well-known resources of the South, it may be said that this section grows the entire cotton crop of the country. About half the standing timber of the United States is found within its borders. It produces three-fourths of the sulphur of the world and dominates the world's sulphur trade. It furnishes a third of the world's output of oil and scientists put the possible production from existing Southern fields at more than four billion barrels of petroleum. The Southern coal fields extend over 88,000 square miles, a coal area many times greater than that of the French provinces, desire for which excited Prussia to war in 1871. In fact, the Southern coal area is twice that of Europe and contains approximately three-fourths of the coking coal of our nation. Over 5,000,000 horse power await the harnessing of Southern streams. The South is the greatest producer of bauxite for the manufacture of aluminium and of barytes for the production of chemical pigments.

The question of the better distribution of chemical and metallurgical industries throughout the country, so that instead of being located along the Atlantic Seaboard where they would be subjected to easy capture on invasion has been so thoroughly discussed by the press during the last two years, that it is hardly necessary in this short article to do more than call attention to the fact that the Government has located both its powder plant and its nitrate plant within the South far removed from the Atlantic Seaboard. Anyone who has crossed the towering ramparts of the Allegheny Mountains to either one of these sites, can bear testimony to the ease with which these localities could be defended.

Power and Fuel

The primary consideration in the establishment of electrochemical industries must of necessity be the cost of power. In the manufacturing sections of the North, where fuel is comparatively dear, practically all electrochemical industries are dependent upon water power. In certain parts of the South, however, very cheap fuel is obtainable and in such sections steam power could, by the installation of efficient power plants, be put on a cost-footing favorable with water power.

In view of the high cost of developing water power, and the fact that most chemical industries had rather purchase this than go to the expense of developing water power themselves, it would seem that for those who are using a moderate amount of electrical power, there would be great possibilities in the utilization of some of the cheap fuels of the South in this direction. The first cost of even the best steam plant will be far below that of the development of the average water power.

Cheap coal is obtainable nowhere just now, but when conditions are favorable, power plants located in the coal fields of the South can, if properly equipped and managed, furnish power at a figure not entirely out of the competition with water power, particularly when the cost of the development and maintenance of the latter is considered and properly taken care of in estimating the price of such power. At Kingsport, Tenn., there is a large steam-power plant which furnishes current for several chemical and electrochemical operations in that section. It is estimated that under normal prices for coal and labor, current can be produced from coal in favorable localities in the South for about three mills a horsepower-hour which is equivalent to about $30.00 a horsepower-year.

To those, however, who feel that they must have water power in order to put their process on a commercial footing, the South offers plenty of undeveloped power. In this connection it might be well to point out that in the mountainous portions of eastern Tennessee, western North Carolina and South Carolina, northeast Georgia and northeast Alabama, the rainfall is greater than that in any other section of the United States and that in this region the climatic conditions are ideal for the maintenance of power transmission lines. The great power streams of the South are the Cumberland, Tennessee, Coosa, Ocmulgee, Saluda, Yadkin, Broad, Catawba, Roanoke, James, Kanawha, New, Pee Dee, Savannah, Tallapoosa, Neuse and Cape Fear.

The greatest power development in the South has been in southeastern North Carolina on the Saluda, the Broad, the Catawba and the Yadkin Rivers. As we have stated it is estimated that the undeveloped power in the Southern rivers amounts to at least 5,000,000 hp. This is about ten times the power now developed at Niagara Falls and is about equal to all the water power at the present time developed in this country. Of this latter, however, not more than 25 per cent is used by manufacturers and a still smaller portion by chemical manufacturers, the lion's share being employed for public utility purposes such as lighting and street railways.

In the territory where the coal fields of Virginia, Kentucky and Tennessee join, is to be found probably a greater proportion of mineral wealth, including salt, than underlies any other section in the world, and the coal here is of the very best grade for steam purposes. It can usually be obtained for $1.00 per ton at the mine. This and also the Birmingham locality and the lignite fields of Louisiana would seem very promising sections in which to establish electrochemical industries employing steam-generated current or chemical plants in which fuel is a considerable item.

Natural gas occurs at numerous points in the South, and West Virginia was the birthplace of the industry in America. Most of this gas now utilized in ways profitable enough to make its employment for power for electrochemical work out of the question. In northern Louisiana, however, we have the great Caddo gas fields and in Texas the Corpus Christi gas district. The Caddo gas is 95 per cent methane and the geological indications are that a supply of long duration is obtainable here. The gas from this field is now used only for domestic and small manufacturing purposes but here would seem to be obtainable cheap power by utilizing the gas directly in gas engines. Incidentally limestone is found close at hand and of course salt occurs in large quantities in southern Louisiana.

Basic Raw Materials

Coming next to the question of the supply of those basic raw materials which play so prominent a part in the chemical arts generally, such as coke and coal products, salt, sulphur, limestone, wood, etc., we will see what a vast storehouse of these the South really is.

We have mentioned the unlimited supply of coal to be found here. Coke is manufactured pretty generally throughout this area, principally in bee-hive ovens. There are some by-product plants, however, notably those around Birmingham, Ala. While, of course, present outputs probably are contracted for, in normal times benzol and toluol could be obtained from these sources, and no doubt other by-product ovens will also follow in the course of time. Edison built his own plant at Woodward, Ala., from which he obtained benzol for his phenol. The South now recovers about 20 per cent of benzol produced in the country.

Limestone, the basis of many chemical and electrochemical industries, is found in beds extending in an almost straight line through West Virginia and Tennessee, eastern West Virginia, the northern corner of Georgia and central Alabama. Another bed extends through central Tennessee and Kentucky, almost the whole of Missouri and the northern part of Arkansas is also underlaid with limestone. A soft limestone or marl also occurs in central Florida. Both high-calcium

and high magnesium limestone are found in this territory and high-grade lime is obtainable from both varieties. Lime from the Virginias is shipped to Niagara Falls for the electrochemical industries and to the chemical plants in New Jersey.

Salt is now produced in Louisiana, Virginia, Texas, West Virginia and Oklahoma to the value of about $1,000,000. The supply in both Virginia and West Virginia is near water powers available for development and in a locality where fuel is cheap. The deposits themselves are practically of unlimited extent. The Weeks Island, La., salt has a purity of over 99½ per cent sodium chloride, while the West Virginia brines contain considerable bromine and calcium chloride, both of which are recovered and marketed. Soda-ash and soda products are made at Saltville, Va., by the Mathieson Alkali Works, one of the largest producers of such chemicals in America.

Sulphuric acid is the basis of so many chemicals that a supply of this is almost essential to the establishment of a chemical industry in any section. As I have said, Louisiana controls the sulphur trade of the world. Also the largest by-product sulphuric acid plant in existence is at Ducktown, Tenn., in a region abounding in mineral resources. Owing to the fact that plants which sold acid to fertilizer factories, at the outbreak of the war diverted their outputs to munition plants, many of the large fertilizer manufacturers in the South were either forced to build acid chambers, or else found it profitable to do so. The result of this will be that with the end of war there will be a very large over production of sulphuric acid in the South.

Virginia has long been known as the most important domestic producer of pyrites, the value of the output of its mines now being over three-quarters of a million dollars. Georgia also produces some pyrite and there are important undeveloped deposits of this mineral in both of the Carolinas. The only domestic producer of arsenic direct from its ores is located in Virginia.

As I have said, the South has over half the standing timber of the country and this latter comprises both hardwood suitable for distillation and the soft woods for pulp, paper and cellulose compounds. The recovery of turpentine from pine tags is now practical and the South has always been the important domestic producer of this material. Tanning extracts are also important Southern products. Those chemicals made from cotton and crude and refined oils made from cotton seed, including the hydrogenation products of the latter oil, should of course form important Southern industries. Important deposits of fuller's earth for cotton-oil purification are found in Florida which is the leading producer in the country and also in Georgia, Texas and Arkansas.

Special Resources

Many plants of medicinal and industrial value now supposed to be only indigenous to certain foreign climes can be raised profitably in the South. The castor-oil bean is one of them and I believe is to be extensively raised this season to furnish oil for aeroplanes. Medicinal plants which can be grown in the central South are digitalis, Indian hemp, hydrastis, belladonna, gentian, horse mint and a host of others. Camphor is now grown along the gulf coast and in Florida and even tea has been raised in South Carolina.

Red and brown hematite ores extend in an almost unbroken belt from Virginia to central Alabama. The red ores carry considerable carbonate of lime and are hence known as self-fluxing ores. For the production of ferro compounds from these ores, we have, in regions where cheap water power abounds, many of the necessary minerals. For the production of ferro-silicon, quartz and quartz sand are found in many parts of the South, notably Virginia, Georgia and North Carolina. Very pure quartz in massive deposits can be found in the latter state. A large part of the titanium now used for steel making comes from Virginia and in the neighborhood from which the present supply is obtained numerous undeveloped properties occur. Chrome ore for the manufacture of ferro-chromium is found in North Carolina but so far the deposits are undeveloped, or for that matter even thoroughly explored, so it is hard to say what the value of these is. Molybdenum occurs in Texas and is now being mined in that state. The phosphate rock for the present supply of ferro-phosphorus, of course, comes from Florida and Tennessee. Extensive manganese deposits occur throughout many parts of the South, notably in Georgia, Arkansas and Virginia. So far, however, none of these deposits has been very extensively developed although they unquestionably represent possible sources of this metal of great value.

The South has long been recognized as the big producer of bauxite, the ore of aluminium. Practically all of this ore, however, has been sent North for working into the metal until recently when the Aluminum Company of America began developments in North Carolina. Arkansas now produces about 90 per cent of the bauxite of the country, while the balance comes from Tennessee and Alabama.

The phosphate resources of Florida and Tennessee are too well known to need more than mention here. It may be said, however, in passing, that the South is the largest user of fertilizer in the country, yet it has purchased its nitrogen from Niagara Falls and Chile in spite of the immense deposits of limestone and coal which traverse this section and of the fact that its inhabitants claim that Southern air is purer than that found anywhere else in the world.

Practically all of the barytes now used in American plants comes from the South largely from Missouri, Tennessee and Georgia. No doubt when Austrian ores again enter this country, the plants along the Atlantic Seaboard will be supplied from this source but there is no reason why local manufacturing plants should not develop in the states mentioned for the manufacture of barium compounds. Fuel and labor here are cheaper and the necessary zinc for lithophone can be found in southwestern Virginia and eastern Tennessee. I believe that the zinc manufactured here is purer than that found anywhere else in this country.

As to other minerals, Georgia produces more asbestos than any other state; Kentucky furnishes fluorspar; Alabama, North Carolina and Virginia all have large deposits of graphite some of which are being worked; gypsum suitable for plaster manufacture is obtained in Virginia, Texas and Oklahoma and celestite the ore of strontium is found (but not so far worked) near Austin, Tex.

Clays suitable for pottery, brick and terra cotta

abound in the South and some of the finest feldspar deposits are also located here. Materials for the manufacture of Portland cement are abundantly distributed and cement and other building materials are everywhere easily available at fair prices.

Labor Markets and Transportation

After all in considering manufacturing operations, one of the most important essentials is labor. The writer has been doing considerable construction in both the North and the South during the last few years and he has found the labor problem more acute in the North than in the South. Good intelligent labor can be obtained in the South at a much lower wage than in the North. Housing conditions are much simpler and the manufacturer who is forced to establish his own colony, will appreciate the advantage of the simpler construction required for this mild climate. The cost of living is also much less in the South than in the North owing to the large supply of farm products which are near at hand and the distance to which these must be sent in order to find a high-priced market.

Another vital problem in the establishment of industries is transportation. Southern railroads have usually been considered more or less of a joke. This is the old story, however, of sending out the truth to catch a lie. The amount of railroad development which has been done in the South in the last ten years is very extensive. The Norfolk and Western Railroad is now recognized in railroad circles as second to none in the country for good management. The Southern, the Chesapeake and Ohio, the Louisville and Nashville railroads and contributing lines to these are now being brought up to a high state of efficiency.

As to markets, except when made for personal consumption, no one would care to manufacture anything if he could not sell it. No matter what the resources of a section are there must be a market place for its produce if it is to prosper. The South has a population of thirty millions who eat, drink, sleep, work and play very much as do the other seventy million Americans. Much of the output of its new chemical plants should be used at home therefore and the great central West is also more easily reached from the northern part of this section than from eastern chemical centers. The chemical industry is a very complicated and intricate structure and often the product of one branch of chemical endeavor finds its way into another. Consequently as each new chemical plant starts operation it will create a demand for another.

Summary

To sum up, it would seem that the South offers excellent opportunities for the manufacture of carbide and for the fixation of atmospheric nitrogen in the form of cyanamid owing to the possibilities of developing cheap power adjacent to inexhaustible supplies of limestone and coal; for the manufacture of aluminium and ferro-alloys in the electric furnace; for the production of phosphate compounds and fertilizers; for the manufacture of barium products including lithopone, owing to the presence of all the raw materials necessary for these in adjacent localities; for the manufacture of soda-ash and other chemicals from salt owing to the extensive brine deposits in certain southern states; for the manufacture of wood chemicals, wood pulp and cellulose substitutes because of the vast amount of timber now standing in this section; for the making of dyes from coal-tar residues; and for industries which will utilize by-product sulphuric acid.

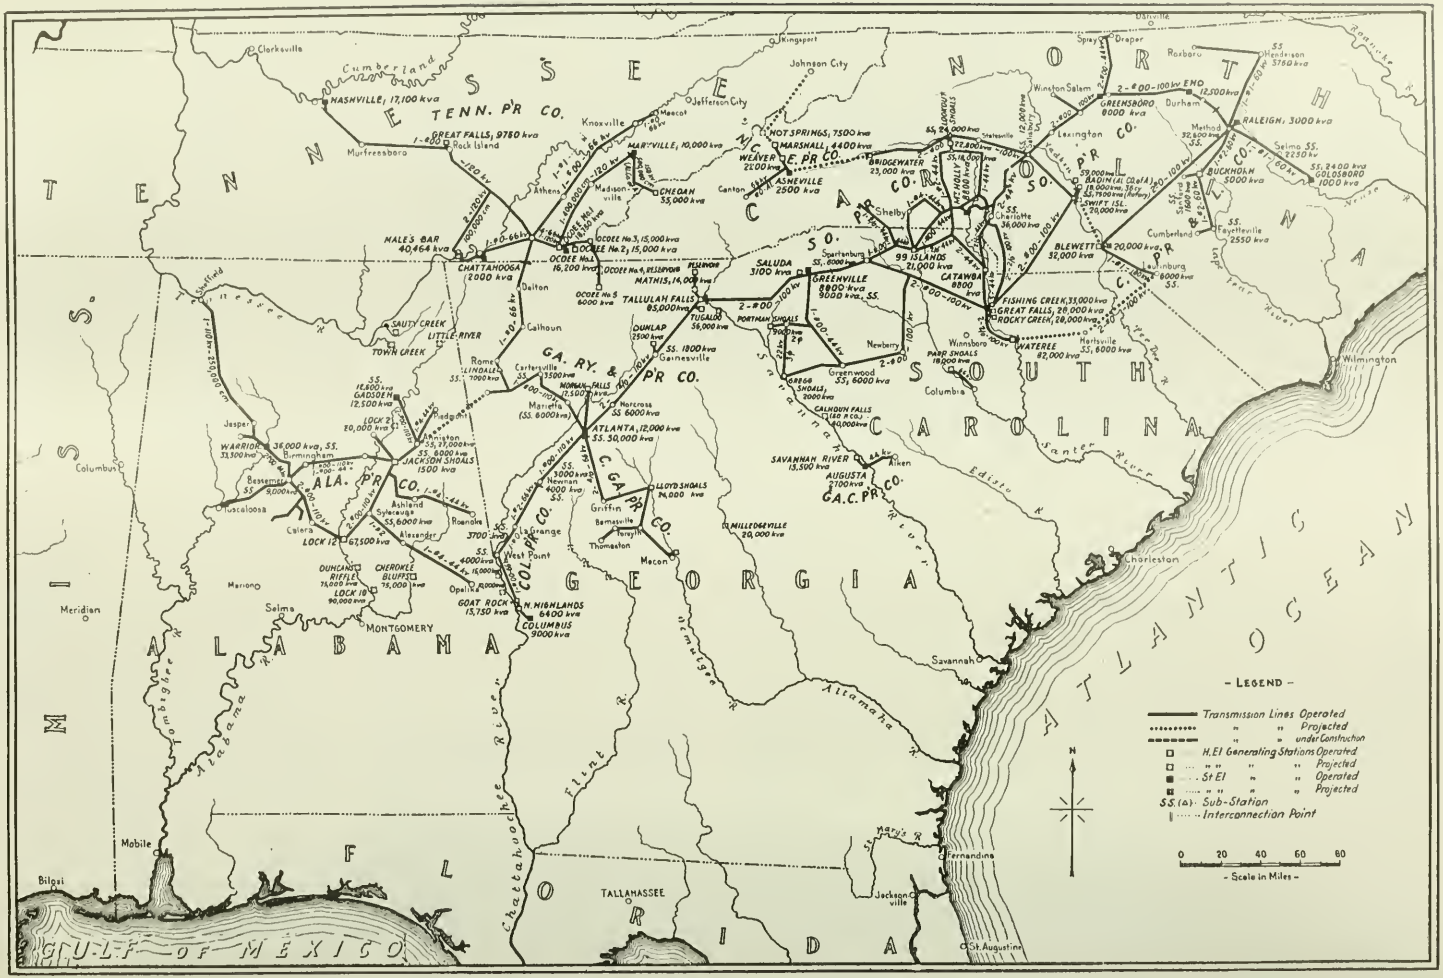
Law Building, Baltimore, Md.

New Priorities List

The United States Fuel Administration will be governed in the distribution of coal and coke by a slightly amended list of priorities recently arranged by the War Industries Boad. Not only will the industries coming under the new classification be given preferential treatment by the Fuel Administration but also in transportation by the railroads.

Aircraft: Plants engaged exclusively in manufacturing aircraft or supplies and equipment therefor.
Ammunition: Plants engaged in the manufacture of ammunition for the United States Government and the allies.
Army and Navy cantonments and camps.
Arms (small): Plants engaged in manufacturing small arms for the United States Government and the allies.
Chemicals: Plants engaged exclusively in manufacturing chemicals.
Coke plants
Domestic consumers.
Electrical equipment: Plants manufacturing same.
Electrodes: Plants producing electrodes.
Explosives: Plants manufacturing explosives.
Farm implements: Manufacturers exclusively of agricultural implements and farm operating equipment.
Feed: Plants producing feed.
Ferro-Alloys: Plants producing.
Fertilizers: Manufacturers of fertilizers.
Fire brick: Plants producing exclusively.
Food: Plants manufacturing, milling, preparing, refining, preserving, and wholesaling food for human consumption.
Food containers: Manufacturers of tin and glass containers and manufacturers exclusively of other food containers.
Gas: Gas producing plants.
Guns (large): Plants manufacturing same.
Hemp, jute, and cotton bags: Plants manufacturing exclusively hemp, jute, and cotton bags.
Insecticides: Manufacturers exclusively of insecticides and fungicides.
Iron and steel: Blast furnaces and foundries.
Laundries.
Machine tools: Plants manufacturing machine tools.
Mines.
Mines: Plants engaged exclusively in manufacturing mining tools and equipment.
Newspapers and periodicals: Plants printing and publishing exclusively newspapers and periodicals.
Oil: Refineries of both mineral and vegetable oils.
Oil production: Plants manufacturing exclusively oil well equipment.
Public institutions and buildings.
Public utilities.
Railways.
Railways: Plants manufacturing locomotives, freight cars and rails, and other plants engaged exclusively in manufacture of railway supplies.
Refrigeration: Refrigeration for food and exclusive ice-producing plants.
Seeds: Producers or wholesalers of seeds (except flower seeds).
Ships (bunker coal): Not including pleasure craft.
Ships: Plants engaged exclusively in building ships (not including pleasure craft) or in manufacturing exclusively supplies and equipment therefor.
Soap: Manufacturers of soap.
Steel: Steel plants and rolling mills.
Tanners: Tanning plants, save for patent leather.
Tanning extracts: Plants manufacturing tanning extracts.
Tin plate: Manufacturers of tin plate.
Twine (binder) and rope: Plants producing exclusively binder twine and rope.
Wire rope and rope wire: Manufacturers of same.

Non-ferrous metallurgical plants are not on the list.



INTERCONNECTED HIGH-TENSION TRANSMISSION SYSTEMS OF THE SOUTH

Interconnected Power Systems of the South

Hydro-electric Systems of Independent Companies Operating in Five States Are Connected Into One Vast Transmission System

HYDRO-ELECTRIC power is a resource that will attract to a community a line of manufacturing and chemical industries that usually seek cheap power as the prime requisite. The development of high-tension transmission systems has become common in many parts of the United States, but it was in the South that the logical and obvious thing was first done by interconnecting a number of systems with resultant advantages and economies. As shown on the map on the opposite page the Southern states can boast a high-tension line approximately 1000 miles long from Nashville, Tennessee, to Henderson, N. C. This ties together the hydro-electric systems of five companies operating in four states. In other words, all the great transmission systems of the South with the exception of that controlled by the Alabama Power Company are interconnected. It is probably only a question of time until all properties will not only be interconnected but possibly owned and controlled by a master organization.

Among the advantages which follow from the interconnection of such systems none is greater than the improvement in the diversity factor. The difference of one hour in time between Henderson, N. C., and Nashville, Tennessee, adds to the normal diversity factor of each system.

The United States Geological Survey has estimated the available power in the headwaters of the Appalachian mountains at 2,800,000 hp. The estimate for all the systems of the South is about 5,000,000 hp. The Appalachian region has an enormous rainfall with a topography that is favorable to the development of low-head power plants. The illustration at the head of this article is typical of the Southern water powers. High heads as a rule do not exist and flumes and penstocks are little used. The absence of lakes in the region makes natural storage of water impossible.

Among the power companies in the United States and Canada having yearly outputs in excess of 100,000,000 kw.-hr., there are three Southern concerns, according to data given in the *Electrical World*, March 23, 1918.

System	Peak Load, Kw	Yearly Output, Kw.-Hr.	Yearly Load Factor Per Cent.
Tennessee Power Co	85,200	547,945,475	73 41
Alabama Power Co	58,250	289,715,125	56 7
Georgia Railway & Power Co	78,200	258,607,882	

INTAKE DAM AT TALLULAH FALLS, GEORGIA RAILWAY AND POWER CO.

Alabama Power Company

The properties owned by the Alabama Power Company[1] include several sites on the Coosa River, one site on the Tallapoosa River, a site on Little River, and sites at Muscle Shoals on the Tennessee River. On these sites approximately 500,000 hp. can be developed. The hydroelectric stations of the company at present in operation are located at Lock 12 on the Coosa River, where a head of 68 ft. is available, and at Jackson Shoals, on Choccolocca Creek, where a head of 22 ft. is available. Sixty-cycle, three-phase energy is generated at 6600 volts in the Coosa River plant and 2300 volts in the Jackson Shoals plant. The company has at present in operation 180 miles of steel-tower transmission lines equipped with suspension-type insulators and 00 stranded copper cable for transmitting energy at 110,000 volts to four substations over private rights-of-way. The substations are situated at Gadsden, Anniston, Jackson Shoals and Magella near Birmingham. Substations operated at 22,000 volts are in operation at Talladega, Leeds, Lovick, Alexander City, Gadsden and Attalla. The high-tension substations

COLUMBUS POWER CO.

are of the outdoor type. It is the purpose of the company to standardize these as to size and type on 3000, 6000 and 10,000-kva. ratings. At present 45,300 kva. is installed in the four substations. The company has 25,000 kw. of available steam auxiliary apparatus, comprising a 12,500-kw. steam turbine station at Gadsden, containing two 6250-kva. units, and a 15,000-kw. steam turbine and reciprocating engine plant. With the available steam auxiliary of 25,000 kw. operating as required and furnishing approximately 7.55 per cent of the total kilowatt-hour output, 62,400 kw. of

[1]Interconnected Systems of the South, Electrical World, May 30, 1914.

YADKIN RIVER POWER COMPANY, BLEWETT FALLS, N. C. HYDRO-ELECTRIC PLANTS FROM NORTHEAST

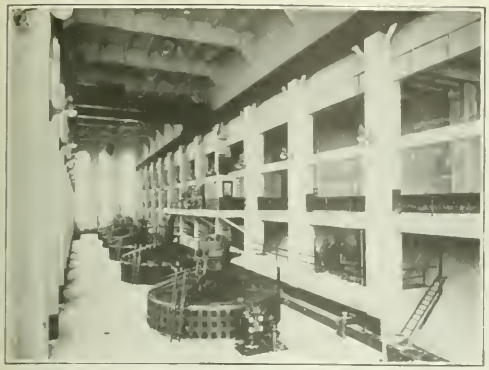
primary power at 50 per cent load-factor can be delivered as soon as another hydro-electric unit is installed. The Anniston substation is a switching station for two 110,000-volt lines which pass through it. The Jackson Shoals substation is also a switching station for three 110,000-volt circuits from the north, south and west. The Magella substation will have an ultimate rating of 67,000 kw.

Carolina Power & Light Company

The Carolina Power & Light Company, in addition to the property owned and directly operated, also controls the Yadkin River Power Company and the Asheville Power & Light Co.

The Carolina Power & Light Company operates the electric light and power service in Raleigh, Goldsboro, Henderson, Oxford, Sanford, and Jonesboro, furnishing electric light and power service for manufacturing properties in Fayetteville, Clayton, Smithfield, Selma, Franklinton, Pine Level and Cumberland. It also supplies under contract the entire requirements of the municipal electric light and power systems in Smithfield, Selma and Clayton and all the privately owned electric light and power systems in Franklinton and Pine Level. The company operates 188 miles of high-tension transmission line connecting two hydro-electric and three steam plants with distributing systems in all the communities served. The larger of the hydro-electric plants is located at Buckhorn Falls on the Cape Fear river and has an installed capacity of 3,300 horsepower. The smaller is a plant of 530 horsepower on the Neuse River near Raleigh. The company has also in reserve a modern steam plant of 5,000 horsepower ca-

GREAT FALLS PLANT OF THE SOUTHERN POWER COMPANY



90,000-HP. GENERATORS—COOSA RIVER INTERIOR VIEW LOCK NO. 12 POWER HOUSE

pacity at Raleigh, one of 950 horsepower at Goldsboro and one of 300 horsepower at Henderson. It operates nine substations with an aggregate capacity of 23,000 horsepower.

The properties of the Carolina Power & Light Company are located in the heart of the North Carolina industrial district. A large part of the electric energy sold by the company is supplied to cotton mills, cotton gins, cotton-seed oil mills, fertilizer works, veneer mills, furniture factories, machine shops, brick plants and other manufacturing establishments, and to municipalities for pumping water.

Yadkin River Development

The Yadkin River Power Company owns and operates a hydro-electric development located on the Yadkin river, at Blewett Falls, near Rockingham, North Carolina, with an initial installed capacity of 32,000 horsepower. It has in operation 184 miles of high-tension transmission lines, located on private right-of-way, and 49 miles of distributing lines, five substations, with a total capacity of 4,100 horsepower; and lighting and power systems in Rockingham, Hamlet, Wadesboro and Lilesville, North Carolina and Cheraw, South Carolina, and an electric power service in Lumberton, North Carolina. The transmission lines are connected with those of the Carolina Power & Light Company and the Southern Power Company. The power station at Blewett Falls is one of the most modern stations in the South. It is 285 feet long by 70 feet wide, three stories in height, and is built of steel and brick with concrete foundations, floor and roof. The dam is of solid concrete construction. It has a total length of 1,470 feet and a maximum height of 50 feet. The dam has created a reservoir eight miles in length with a total area of 2,500 acres. The station was placed in regular operation in June, 1912.

Like the properties of the Carolina Power & Light Company, those of the Yadkin River Power Company are located in the Carolina cotton-mill district, and a large part of the electric energy sold by it is supplied to cotton mills, cotton gins and cotton-seed oil mills. It also supplies power to numerous other industrial plants, such as fertilizer works, veneer mills, furniture factories, brick plants and railroad shops, and to municipalities for pumping water.

Columbus Power Company

The Columbus Power Company[2] has three hydro-electric developments on the Chattahoochee River, two at Columbus having an aggregate rating of 9000 kva. and one at Goat Rock, 15 miles north of Columbus, having 13,750 kva. installed, making the total available 22,750 kva. The City Mills development at Columbus comprises five generators with an aggregate rating of 1000 kw., the head being 10 ft. The North Highlands development has six generators, with an aggregate rating of 6900 kw., and waterwheels operating under a head of 42 ft. The Goat Rock development, where a head of 72 ft. is available, has three generators, two of which are rated at 3750 kw. and the other at 5000 kw. Three-phase, sixty-cycle energy is generated at 5500 volts and 11,000 volts. Two 4000-kw. transformers step up the potential to 66,000 volts for transmission. A 11,000-volt line on wooden poles with pin-type insulators connects the Columbus and Goat Rock properties, and a 60-mile steel-tower line equipped with suspension-type insulators and operating at 66,000 volts extends from Goat Rock at Newnan. There is

DUNLAP PLANT, GEORGIA RAILWAY AND POWER CO.

ROCKY CREEK PLANT OF THE SOUTHERN POWER COMPANY

LOCK 12 HYDRO-ELECTRIC PLANT—DOWN-STREAM VIEW

18 miles of wooden-pole line operating at 11,000 volt connecting Newnan and Hogansville. Four main substations are connected to the system, one at Columbus rated at 1600 kw., one at West Point rated at 1875 kw., one at La Grange rated at 1875 kw. and the fourth at Newnan rated at 4000 kw. The system operates continuously on a 40 per cent load-factor basis, and auxiliary steam generating apparatus of the capacity of of 3000-kw. turbo-generators is available. Provision is made for the transfer of 3000 kw. between the Columbus Power Company's system and the system of the Georgia Railway & Power Co.

Georgia Railway and Power Co.

The present coal supply conditions emphasize the importance of existing water-power generating plants and the vital need of additional developments.

The 100,000-hp. plant of the Georgia Railway and Power Company at Tallulah Falls was barely finished when the rapid increase in the demand for hydro-electric power forced the company to undertake the construction of additional water-power developments, which, when completed, will nearly double the present capacity of its existing water-power plants.

The growth of the business in the past six years is shown in the following table of yearly outputs in kilowatt-hours:

1912	68,400,642	1915	179,976,596
1913	80,763,025	1916	211,872,638
1914	145,684,803	1917	258,607,802

This shows an increase in that period of nearly 300 per cent or, in other words, the volume of business almost doubled twice.

The water power furnished by the company to its customers in 1917 would have required approximately 475,000 tons of coal if generated by them by steam. The additional water power which it is estimated will be generated at the new plants now under construction, and which has already been largely sold, will take the place of and save approximately 400,000 tons of coal annually—a total combined saving of approximately 875,000 tons of coal per annum.

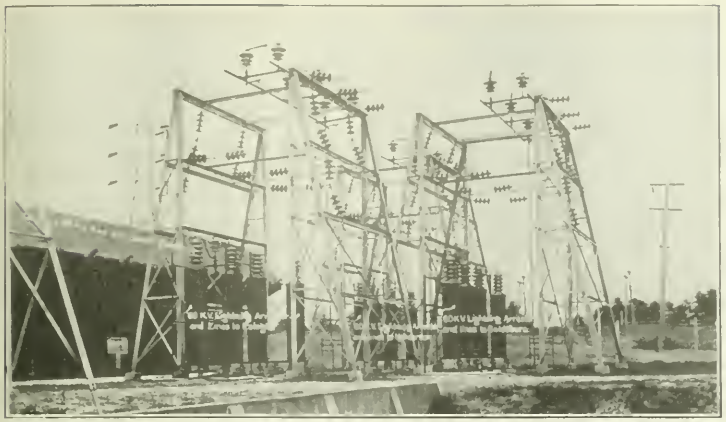
The new developments now being constructed are:

Burton Storage Reservoir

(To be in service by the end of year 1918)

The Burton storage reservoir is three miles north of the present Mathis storage reservoir, and will flood approximately 3000 acres of land. It requires the construction of a dam 700 feet long and 100 feet high of cyclopean masonry. The reservoir will store approximately five billion cubic feet of water. The water contained in this reservoir, exclusive of the average flow of the river, will produce at the Tallulah Falls and Tugaloo generating plants 65,000,000 kilowatt-hours and will increase the annual capacity of those plants to that extent. This reservoir will also make possible the equalization of the river flow, or in other words, the even distribution of all available rainfall run-off from

LOCK 12 HYDRO-ELECTRIC PLANT—UP-STREAM VIEW



METHOD, (N. C.) OUTDOOR SUBSTATION LOOKING NORTH. CAROLINA POWER AND LIGHT COMPANY

its contributary water shed throughout every month in the year, the stored water being drawn out for use in the dry months and replaced in the wet season. The water that can be stored in this reservoir is equivalent to the available energy in 130,000 tons of coal.

Tugaloo Development

The Tugaloo development is situated about two miles below the present Tallulah Falls power house on the Tugaloo river where the Tallulah and the Chattooga rivers come together and form the Tugaloo. The water available at this point for power purposes come from both the Tallulah and the Chattooga rivers. The average flow of the river, including the effect of the Mathis storage reservoir, it is estimated will produce at this plant approximately 120,000,000 kilowatt-hours. It will require only one and one-half miles of transmission line to connect this development with the present Tallulah Falls transmission lines. The Tugaloo dam of cyclopean masonry is 800 feet long and 140 feet high. The Tugaloo plant will develop approximately 65,000 hp., and it is estimated that two years time will be necessary in which to complete it.

Sixth Unit

(To be in service during the summer of 1918)

The Tallulah Falls power plant was constructed and designed for six units of 12,000 kilowatts or about 17,000 horsepower each. Five units are now installed. The sixth unit has been ordered and will be ready for service sometime during the summer of 1918.

Contracts were let for all the required equipment for the three developments during the summer of 1917 and construction is now actively under way.

The estimated total cost of this construction is $5,000,000. The necessary financing to carry on the work was completed in June, 1917. The company was fortunate in this respect because the war has since brought such changed financial conditions that the necessary capital could not be secured at the present time and this has been continuously true since the financial arrangements were concluded.

The Georgia Railway and Power Company upon completion of the plants now under construction will have water-power plants of approximately 200,000 horsepower developed and in service.

The company controls approximately 300,000 undeveloped horsepower in addition, or a total developed and undeveloped of approximately 500,000 horsepower.

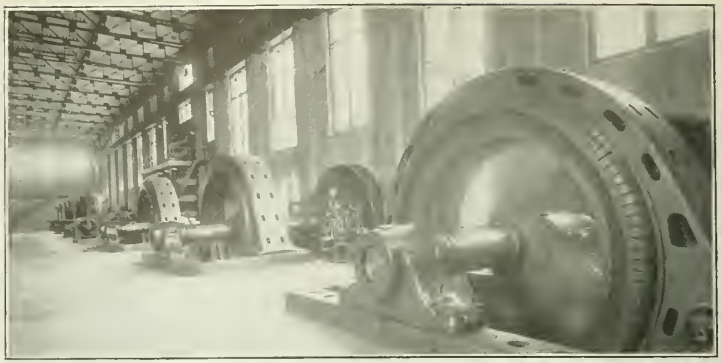
A very large part of the power generated by the company is being used by enterprises making war materials or supplies necessary to the successful prosecution of the war. This shows how doubly vital it is in war times that money for such developments should be available.

It also points the lesson that many of us appreciated years ago, viz., the necessity of a broad and generous policy on the part of the Government in the development of the water powers of the nation.

THE TALLASSEE POWER COMPANY, YADKIN RIVER, BADIN, N. C.

Water power should be provided to meet the increasing demand due to the war. But war conditions have made money unobtainable through the usual banking channels. From now on and as long as present conditions exist such developments cannot be made unless the national government will furnish the needed capital.

The French government realized early in the war the vital need of largely increasing the available power for industrial purposes from other sources than coal and is now constructing water-power developments in Southern France on a large scale under the direction of an American engineer.



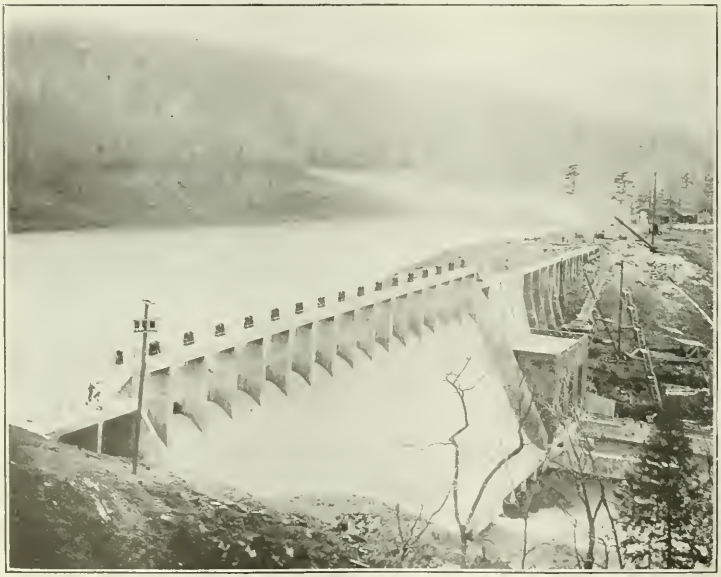
YADKIN RIVER POWER COMPANY. 3-4500 KVA, 3-6000 KVA, 4000 VOLT, 60 CYCLE G. E. GENERATORS

Coal Saved by Hydro-electric Development

The power actually furnished by the Georgia Railway and Power Company, in 1917, if generated by its customers by steam, would have required 11,875 cars of coal of 40 tons capacity each, and the estimated power which will annually be generated by the plants now being constructed, will be the equivalent of 10,000 cars of coal of 40 tons capacity each additional, or a combined saving in coal consumption per annum of 21,875 cars of coal of 40 tons capacity each. If the remaining 300,000 horsepower of undeveloped water power controlled by the company could be developed and put to work, the saving would be two and one-half times as great or a total of 54,687 cars of coal of 40 tons capacity each, or 2,187,480 tons of coal conserved with all its collateral economies.

If capital were now available for the construction of the necessary generating plants sufficient to utilize the undeveloped water power controlled by the Georgia Railway and Power Company, and the national government would bring about the electrification of the steam railroads, all the important railroad mileage in Georgia would be operated by electric power generated by the Georgia Railway and Power Company. The operating expenses of the railroads themselves would be materially reduced, their service much improved, and in addition the coal now consumed by them conserved, and the present regular business of the company supplied and developed as at present.

Our armies at the front will be of no use unless supplied with food and equipment. This necessitates the development and speeding up of most industries to the top notch of production. Business essential to the war must produce as never before to supply our armies at the front, our industrial armies at home, and in addition to furnish taxable values to foot the bills. To this end the efforts of a vast industrial army at home, co-ordinated to supply the needs of the army at the front, are as necessary as the fighting men themselves. Present conditions emphasize the value of water power as never before. Is not this situation deserving of prompt attention by the national government? The President of the United States thinks so, because he called the attention of Congress specifically to the development of water powers in one of his most recent messages.



MATHIS DAM, GEORGIA RAILWAY AND POWER CO.

YADKIN RIVER POWER COMPANY, BLEWETT FALLS, DAM AND POND

Southern Power Company

The Southern Power Company[3] is connected to the Carolina Power & Light Company at a point between Durham and Raleigh, N. C., as indicated on the map, and with the Georgia Railway & Power Company at Tallulah Falls. The location and maximum ratings of the company's various stations are given in the accompanying table.

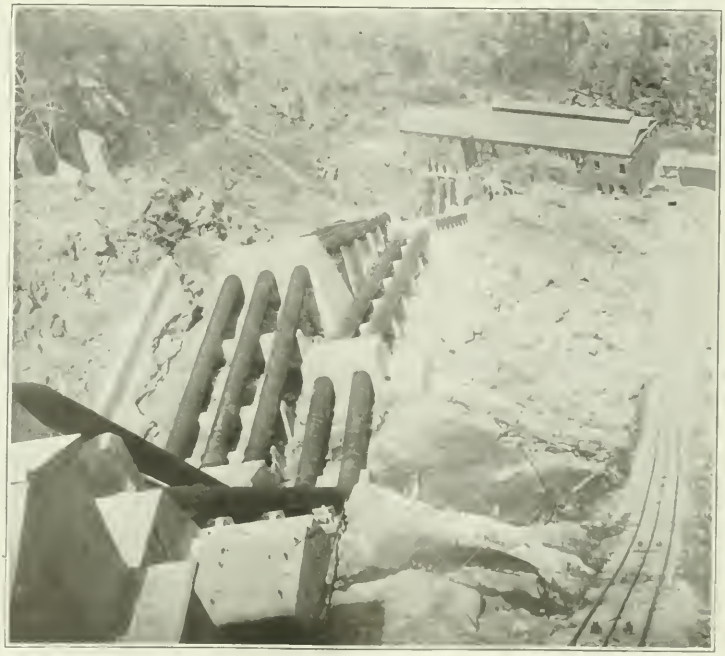
DATA ON SOUTHERN POWER COMPANY'S STATIONS

Location	Maximum Rating	Head, Ft.
Great Falls, S. C.	24,000 Kw.	72
Rocky Creek, S. C.	24,000 Kw	63
Ninety-nine Islands, S. C.	18,000 Kw	72
Catawba, S. C.	6,600 Kw.	25
Lookout Shoals, N. C. (under construction)	24,000 Kw.	76
Greenville, S. C. (steam)	8,000 Kw.-a.	
Greensboro, N. C. (steam)	8,000 Kv.-a.	
Mount Holly, N. C. (steam)	8,000 Kv.-a.	

Electricity is generated at 2200, 6600 and 11,000 volts, three-phase, sixty-cycle, there being one 8000-kva, 2300-volt and two 8000-kva, 11,000-volt steam-driven generators, twenty-two 3000-kva, 3000-volt generators, three 7800-kva, 6600-volt generators, four 900-kva, and 750-kva, 11,000-volt generators. The last thirty-three units are of the waterwheel type. There are also connected to the system sixty-five high-voltage transformers having an aggregate rating of 169,400 kva. The lines of the company cover a territory of 300 miles in a northeasterly and southwesterly direction and 100 miles in a northwesterly and southeasterly direction. The first transmission system of the company is designed for 11,000 volts. With the expansion of the company and its activities, a 44,000-volt transmission system was built, and all of the recent transmission lines erected by the company have been designed for 100,000 volts. All lines are looped in together, and the 11,000-volt and 100,000-volt systems are tied together with tie-in transformers. Aluminum and copper are both used for conductors, the size ranging from No. 4 solid copper to No. 000 stranded. By far the greatest amount of the lines are of No. 00 copper stranded and No. 00 equivalent aluminum stranded. This is run on both steel towers and wooden poles with pin-type and suspension-type insulators, depending upon the voltage. There are 103 substations connected to the system, containing 352 transformers with an aggregate rating of 241,162 kva.

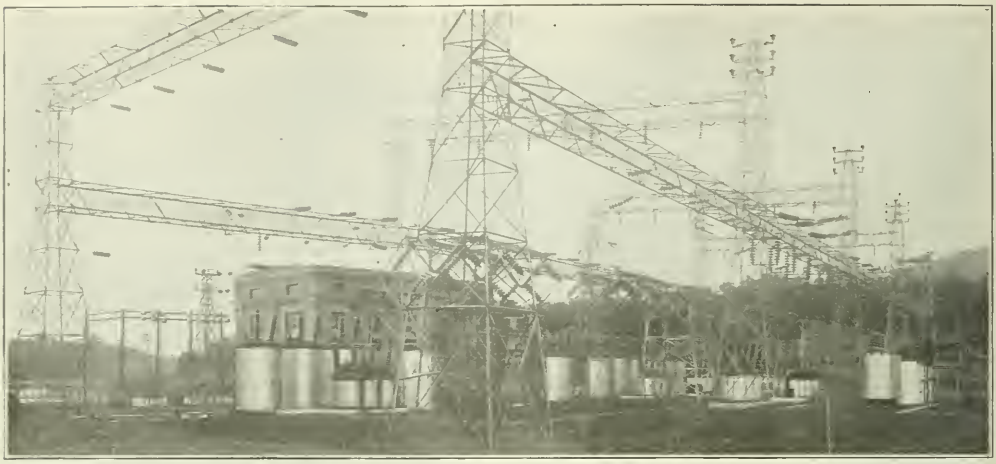
The circuits of the Southern Power Company are connected on the north with those of the Carolina Power & Light Company with two 100,000-volt lines. The amount of power that can be transferred is limited only by the carrying capacity of these lines, as no transformers are required in order to effect this connection. On the south the Southern Power Company's system is connected with that of the Georgia Railway & Power Company at Tallulah Falls, with two 100,000-volt lines, and the power which can be transferred between the two companies at this point is limited only by the carrying capacity of the lines.

It should be pointed out that the rating of the hydroelectric stations of the Southern Power Company is based upon the continuous rating for the continuous amount of twelve-hour power which the station can generate for eight months in the year. The company maintains three 8000-kva. turbo-generator steam plants



PENSTOCKS CONNECTING FOREBAY WITH POWER HOUSE, GEORGIA RAILWAY AND POWER CO.

[3]Ibid.



SUBSTATION—ALABAMA POWER COMPANY, COOSA RIVER HYDROELECTRIC PLANT

for emergency and supplementary service. The fires under the boilers are banked, and all three stations can be got under way to feed energy to the lines within fifteen minutes.

Tennessee Power Co.

The present hydro-electric stations owned and operated by the Tennessee Power Company are as follows:

Ocoee No. 1, located in Polk County at Parksville, Tennessee, on the Ocoee river, approximately 50 miles from Chattanooga. The equipment in this plant consists of five horizontal direct-connected water-wheel-driven generators, each one having a capacity of 3750 kilowatts, the total station capacity being 18,750 kilowatts. The dam at this plant backs up the Ocoee River, forming a lake approximately eight miles long. Sufficient water is impounded to operate the station over a period of two or three weeks during reduced stream flow.

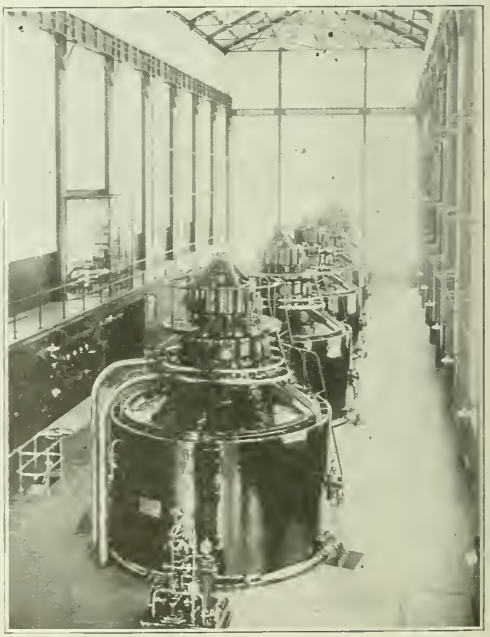
Ocoee No. 2, located in Polk County on the Ocoee river, about ten miles east of Parksville. This plant is equipped with two horizontal water-wheel-driven generators, each having a capacity of 7500 kilowatts, the total capacity of the station being 15,000 kilowatts. This plant uses the stream flow from the Ocoee river, which is diverted by means of a low dam, five miles above the power station, from which the water is conveyed by means of a flume to a forebay above the power house. The operating head at this plant is 255 feet.

Great Falls Station, located at the northwest corner of Warren County, about half way between Nashville and Chattanooga. This plant uses the flow of the Caney Fork and Collins rivers. A low concrete dam is located just below the confluence of the two rivers which diverts the two streams which are conveyed to the water wheel by means of a tunnel and penstock. The plant is equipped with one vertical water-wheel-driven generator, the capacity being 9750 kilowatts.

Hales Bar, located on the Tennessee river about 20 miles west of Chattanooga. This plant is equipped with fourteen 3000-kilowatt vertical turbines, the total capacity of the station being 42,000 kilowatts. The concrete dam across the river at the power house site backs up the water and makes the river navigable to Chattanooga. The spillway is 1200 feet long. The dam is provided with a boat-lock which is operated by the government.

The combined capacity of the present hydro-electric stations is 85,000 kilowatts.

Proposed hydro-electric developments: Additional developments have been considered, and rights ob-



GENERATORS, TALLULAH FALLS POWER HOUSE, GEORGIA RAILWAY AND POWER CO.

TALLULAH FALLS POWER HOUSE, GEORGIA RAILWAY AND POWER CO.

tained for three more stations on the Ocoee river, to be known as Ocoee No. 3, Ocoee No. 4 and Ocoee No. 5. The additional capacity from these three stations will be in the neighborhood of 35,000 kilowatts.

Steam Plants: The Tennessee Power Company has an arrangement with the Chattanooga Railway and Light Company, the Nashville Railway and Light Company and the Knoxville Railway and Light Company whereby the steam plants at these three cities may be operated at the direction of the Power Company to supplement the output from the hydro plants during low water. The capacities of the steam stations are as follows:

	Kilowatts
Chattanooga	5,000
Nashville	15,000
Knoxville	4,000
Total	24,000

The Tennessee Power generates the electrical energy used in Chattanooga, Nashville, Knoxville and a large number of the small cities in eastern Tennessee. In addition it supplies power to the Aluminum Company of America at Maryville, Tennessee, 16 miles south of Knoxville, and also to the American Zinc Company at Mascot, Tennessee, 15 miles northeast of Knoxville. The total transmission line mileage is aproximately 600 miles.

The rates for electrical energy are in accordance with the following tabulation:

"A fixed charge of $1.25 per month per kilowatt of maximum demand based on the highest fifteen minute demand during the month, but in no event shall the fixed charge be less than 60% of the total kilowatt capacity contracted for.

"In addition to the above demand charge the following kilowatt hour charge for electrical energy consumed during the month:

	Kilowatt-Hours
4c. per kw.-hr. for the first	500
2c. per kw.-hr. for the next	1,000
1½c. per kw.-hr. for the next	1,500
1c. per kw.-hr. for the next	17,000
0.7c. per kw.-hr. for all over	20,000

"A discount of five (5%) per cent will be allowed upon all bills paid within ten (10) days from their date."

Dyestuff Association Officially Organized.—The Board of Governers of the American Dyestuff Manufacturers' Association met on April 4, at the office of its counsel, Benjamin M. Kaye, 149 Broadway, to elect officers, execute the certificate of incorporation issued by the Secretary of State at Albany, and adopt the constitution and bylaws. The officers elected were: President, Morris R. Poucher of E. I du Pont de Nemours & Co., Wilmington, Del.; First Vice-President, L. A. Ault of Ault & Wilborg, Cincinnati, Ohio; Second Vice-President, Frank Hemingway of Frank Hemingway, Inc., New York; Secretary, C. Cyril Bennett, manager of the Color Trade Journal, New York, and Treasurer, Charles Jenkinson of the National City Bank, New York. Within a short time the association will start an intensive drive in propoganda work in order to acquaint the American public with the enormous strides made in the color industry in this country since the start of the European war. One of the undisguised objects of the new association is to prevent German aggression in the dyestuffs industry in this country after the war. Membership in the organization is open to American manufacturers of dyes and intermediates.

Chemical Trade Specifications.—A definite need which is becoming apparent as our chemical industry expands, is a publication of trade specifications and standards covering those chemical products which are general articles of commerce. This need will become more insistent as new and inexperienced men engage in the buying and selling of chemicals. Their unfamiliarity with trade terms and customs will be fruitful of disagreements unless recognized standards can be freely consulted and made the basis of negotiations. In the hope and expectation of meeting this need Dr. Wallace P. Cohoe of New York, with the cooperation of METALLURGICAL AND CHEMICAL ENGINEERING, has begun the collection of data that will embody a general statement of current trade standards, and which will be published in book form by the McGraw-Hill Book Co. as soon as the compilation can be completed.

Electric Furnaces Discussed by Faraday Society

AT a meeting of the Faraday Society on Thursday, Feb. 14, at Manchester, England, a general discussion took place on electric furnaces. The discussion was presided over by Professor C. A. EDWARDS of the University, Manchester.

The Chairman, in introducing the subject, gave a short account of the history of electric smelting since Siemens in 1878 patented his first small coke electric furnace. In 1904 there were only four electric furnaces in Europe and America; in 1913 there were 114. Development since the war had been phenomenal.

Mr. H. ETCHELLS read a paper on *"Applications of Electric Furnace Methods to Industrial Processes."*

The author referred to the growth of electric furnace industries during the war, which was due not only to the greater output demanded, but to a certain extent because the electric furnace enabled us to use raw materials which were formerly considered inferior for the quality of product desired.

In dividing electric furnaces under the three headings *Induction*, *Resistance*, and *Arc* types, the author considered that only the latter two types may be looked to for future extensive development. A plea was made for the greater development of the resistance furnace, which from the electric load viewpoint was ideal, giving high load factor, high power factor, and very slight fluctuation. The Bailey furnaces were mentioned as the only furnaces of this type which had hitherto attained an industrial development in large units.

The greatest development of electric furnaces, it was pointed out, had taken place in connection with the steel industry, and especially in regard to the production of special high quality steel castings. In the author's opinion, the electric furnace is not fulfilling its highest function in the foundry when used for simply melting steel scrap to turn out an unrefined product on an acid lining.

The success attained by the Greaves-Etchells furnace in high-speed steels was specially indicated, some Sheffield firms having dispensed with the crucible process and adopted the electric process whole-heartedly.

The unsatisfactory performance of refractory lining materials at present marketed was commented upon, and the author stated it as his belief that satisfactory linings would not be available until electrically fused refractories were put on the market.

Mr. J. BIBBY read a paper on *"Electric Steel Refining Furnaces."* He said the development of the electric furnace for steel making is almost certain to take place in the direction of large furnaces. As furnaces get larger new conditions appear, which require consideration in the design, but economies can be effected in consumption of current, refractory materials and labor. On small furnaces, up to 5 tons' capacity, two electrodes are suffifficient, but on the larger furnaces it is advisable not to concentrate the heating zone in two places, but to distribute it by having four electrodes over a circular bath. Further, on large furnaces large currents are required, and up to the present we only have electrodes which will take currents of, say, 10,000 amp., so that where more than 20,000 amp. are required, more than two electrodes are required for this reason. In the use of four upper electrodes we are confronted with an electrical problem. It was explained in the paper that whatever system is adopted it must be such that when equal currents are flowing through each of the arcs, then equal currents must be taken from each of the three high-tension mains, and each of these three primary currents must be practically in phase with its voltage in order to secure a higher power factor. Further, for metallurgical reasons it is considered desirable that a certain amount of current should flow vertically through the hearth to a fifth fixed electrode beneath it. We therefore require some system which will impress an equal voltage between each upper electrode and the hearth electrode, so that when equally adjusted equal currents, and therefore four equal heating zones, will be obtained.

The condition is met if we can obtain on the furnace side of the transformers four equal phases, one for each electrode, and a common return to a neutral electrode beneath the hearth. In short, we require a four-phase, five-wire system. This can be obtained by simply having two sets of two phases working in parallel, but this system has serious electrical objections. The problem has been satisfactorily solved by the Electro-Metals four-phase arrangement, which consists of three single-phase transformers. Two of these transformers have their terminals connected separately to the four upper electrodes. A tapping is taken from the middle of the third or Teaser transformer to the hearth electrode, and the terminals of the Teaser transformer are connected to intermediate tappings on the main transformers. A closed system is thus obtained when arcs are struck between the four upper electrodes and the bath of metal. This system gives an equal voltage in each of the arcs and therefore equal heating zones, and also when the electrodes are regulated for equal currents, then equal currents are taken from the three primary mains. The average power factor of the system on a non-inductive load is unity. Further advantages of the system are that when the furnace is under poor regulation the primary currents remain tolerably balanced with a high power factor.

A paper on *"Electric Furnace Control"* was presented by Mr. A. P. M. FLEMING and Mr. F. E. HILL.

The methods of control are classified as follows:

I. By Variation of Voltage

(1) Alteration of the ratio of the main transformer by cutting out a portion of the primary winding.

(2) Alteration of the ratio of the main transformer by an auxiliary winding which can be connected up in series with or in opposition to the main winding.

(3) Use of a primary booster transformer to vary the secondary voltage by altering the pressure supplied to the primary.

(4) Use of a secondary booster transformer, the secondary of which is in series with the main secondary, the booster primary being in parallel with the main primary.

(5) Control by means of a motor-generator; a method rarely used.

II. By Variation of Current

Control by this method is accomplished by raising or lowering the electrodes. It may be employed as an auxiliary method to any of those previously described. Examples of both hand regulation and automatic regulation are given in the paper.

Synopsis of Recent Metallurgical and Chemical Literature

Comparison of High-Temperature Scales. — E. P. HYDE and W. E. FORSYTHE of the Nela Research Laboratory presented a paper at the Rochester meeting of the American Physical Society giving the final results of a study on the above subject, and which present a very clear idea of the relative accuracy with which carefully made temperature determinations can be compared. The intercomparison of the temperature scales of the Bureau of Standards, the Physical Laboratory of the University of Wisconsin, the Research Laboratory of the General Electric Company at Schenectady, and the Nela Research Laboratory was carried out through measurements made on several tungsten-filament lamps, the exact point at which it was desired to have the temperature measured being indicated either by a pointer, a notch on the supporting lead, or a small notch on the filament itself. High-temperature scales are for the most part based on the temperatures of standard melting points for the most part obtained inside a standard black-body furnace and extended beyond these points by means of radiation laws. All the above laboratories (except the University of Wisconsin, which used palladium at 1822 deg. K.) base their temperature scale on the melting point of gold (1336 deg. K.) and extrapolate by means of Wien's equation using for C_2 14350 $\mu \times$ deg. There are three sources of error: (1) in obtaining the temperature of the melting point, (2) in the blackness of the furnace used, and (3) in the extrapolation, and the combination might well lead to large uncertainties in the final result. The results in deg. K. are given in the following table, in part, reduced to the melting point of palladium. As the red-glass screen used in the different laboratories varied somewhat, it was necessary to reduce the temperatures to the same wave length (0.665μ). Holborn-Kurlbaum pyrometers were used.

Lamp No.	T-16-B	T-30-C	T-17-C	T-18-B
Nela	1618	2756		
Schenectady	1613	2752

Wisconsin			2511	2121
Nela			2497	2107

Furnace Control by Optical Pyrometers.—The making of optical glass is strictly dependent upon the furnace temperatures, as noted by C. N. FENNER of the Geophysical Laboratory (The Physical Review, Vol. XI, p 141.) If the temperature of melting and fining is a little lower than supposed the resulting glass will be full of bubbles, or even milky. On the other hand, too high temperatures will corrode even the best melting pots, contributing stones to the melt, sometimes corroding through. These important considerations limit the operations to a temperature range between 1300 and 1400 deg. C. The furnaces in the Bausch and Lomb plant had been equipped with platinum thermocouples, but rapid contamination by furnace gases caused unsatisfactory service. A Morse instrument has been substituted with excellent results, the furnace men being easily educated to its use. Previously to making the change it was found that the calibration chart furnished by the makers was correct at all points to within a very few degrees or the limit of error. A more important test was whether the furnace walls radiated as a black body. This was investigated by means of a platinum thermocouple contained in a Marquardt porcelain tube fixed in the end of a water-cooled iron pipe extension, through which the lead wires extended. By using this simultaneously with the optical pyrometer, the temperatures of the walls as observed by optical and thermo-electric were almost identical. At temperatures lower than 1300, however, the optical readings were high, owing to the error caused by the reflection of the flames from the glazed walls.

Ferrous Metallurgy in Canada.—DR. ALFRED STANSFIELD, in a paper on "Recent Advances in Canadian Metallurgy" before the March meeting of the Canadian Society of Civil Engineers notes that a recent study of the Lake St. John (Quebec) District has caused him to modify his opinion expressed after a study of the Swedish industry just prior to the war that it would not be profitable to produce electric pig iron in Canada, since at Lake St. John a high-grade white iron containing titanium appears to be a desirable possibility. The Canadian production of electric steel has increased from 61 tons in 1914 to approximately 50,000 tons in 1917, mostly as shell billets from steel scrap. Several furnaces are in operation in and about Montreal, the Munitions Board has built ten 6-ton furnaces at Toronto, and the Armstrong Whitworth Company has built a plant for the production of electric tool steel at Longueuil. While the furnace at Belleville has made much good steel from titaniferous ore, it has been found cheaper to use scrap. This furnace and another at Orilla has recently been fully occupied with the production of ferro-molybdenum. Before the war from eight to ten thousand tons of ferro alloys, mostly ferro-silicon, were made annually at Welland by the Electro-Metals, Ltd. This alloy is now made also at Shawinigan. In 1916 the production of ferro alloys had increased to 28,600 tons, valued at $1,777,000, and included a large tonnage of ferro-phosphorus made at Buckingham, P. Q., by the Electric Reduction Company.

The Electrodeposition of Zinc.—In a paper to be presented at the fall meeting of the American Institute of Mining Engineers, C. A. HANSEN, of the General Electric Company, gives some important information on the proper practice in electrolytic zinc. He postulates two major reactions in the cell: first, zinc deposition at the cathode according to Faraday's constant, and second, corrosion of this zinc by the solutions according to the surface exposed and the chemical activity of the solution as mainly determined by its acidity. He also discusses the meager data on the effect of temperature on the deposition, showing a reduced current efficiency in pure solutions at higher temperatures, and he shows that its bad effect may be obviated by (a) flushing out the unsatisfactory solution, (b) cutting down the cell current, reducing the acid concentration and therefore the corrosion, as well as the energy input, and (c) using glue, lanolin, and other organic reagents whose effect,

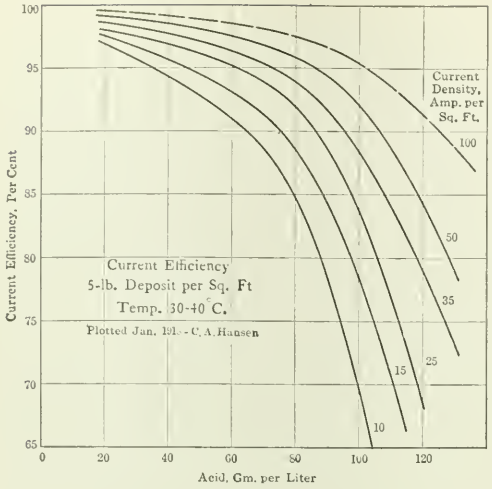

FIG. 1.

though beneficial, is cursory. According to the author's postulates, the difference between 100 per cent current efficiency and the actual is a measure of the corrosion rate. Since the latter increases with the current density (high current densities yield rougher deposits, particularly with low acid concentrations), this conclusion agrees qualitatively with facts. Values from the curves, Figure 1, do not agree as well with observed results as expected, and a second variable is thought to be the lack of zinc which exists in high acid solutions. The voltage data of Figure 2 were determined in a special cell so constructed as to avoid the errors of small cells, and include contact and other losses. Direct current data for the electrolysis

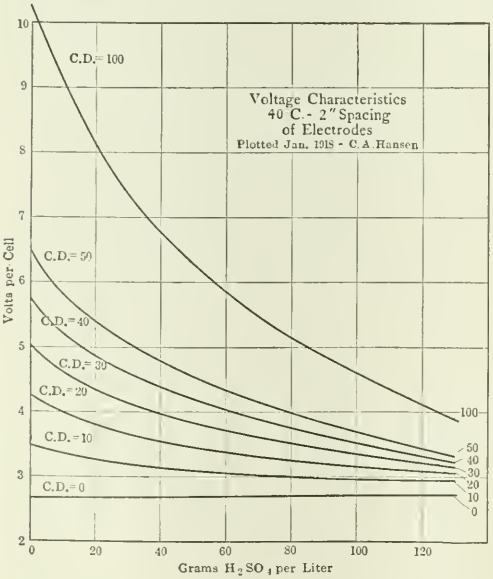

FIG. 2.

of pure zinc sulphate solutions should be multiplied by the factor 1.145 or 1.21 depending upon the electrical conversion apparatus in use. The cost of the cell room is almost inversely proportional to the current density. High leach-tank temperatures which are desirable are largely had by low current efficiency, which is undesirable.

Non-cumulative impurities in the electrolyte are copper, cadmium, arsenic, antimony, iron, manganese, silica and alumina. Copper and cadmium are precipitated with zinc, and will come down in the early cells

Cu or Cd, milligrams per liter	0	5	10
Acid, 30 gm. per liter	99	93	90
Acid, 60 gm. per liter	96	87	81
Acid, 90 gm. per liter	93	76	65

of a cascade, in which the current efficiency will no longer correspond to that expected for pure solutions.

Arsenic and antimony are not precipitated, but remain in the effluent. They are less dangerous in manganese-free electrolytes; with manganese a variation from 0.0003 to 0.001 gram antimony per liter made the difference between excellent and impossible cell-room practice.

The behavior of iron is less consistent, but it evidently serves no good purpose. Manganese by itself exerts no harm. The sulphate is oxidized in part to permanganic acid at the anode, reacting with the sul-

Acid, Grams per Liter	Arsenic, Milligrams per Liter			Antimony, Milligrams per Liter		
	0	5	10	0	5	10
30	99	94	90	99	91	84
60	96	83	77	96	80	65
90	93	66	50	93	63	35

phate and throwing out manganese dioxide at the surface of the anode itself. This dioxide adheres with low acid concentration, with higher it drops as a slime always containing substantially the same amount of lead peroxide.

Some cumulative impurities are unimportant; such are the alkali metals and magnesium. Others, such as nickel, cobalt, vanadium and possibly uranium affect the cells when in such small amounts that chemical analysis can hardly detect them. The behavior of the cell itself is thus the surest check on the thoroughness of the purification. The effect of cobalt is shown by the following table:

Co, Milligrams per Liter	0	5	10	15	20
Acid, 30 gm. per liter	99	96	93	91	87
Acid, 60 gm. per liter	96	90	85	77	64
Acid, 90 gm. per liter	93	80	70	55	30

Pure solutions invariably yield excellent deposits, wholly without blemish on the starting sheet side. Pinholes are almost always found when impurities in quantity of tenths of milligrams per liter are present. If serious quantities are present, a good deposit may form for some hours, and then start corroding at such a rate that it entirely disappears, only to be redeposited later. It is the realization that thorough purification is a necessity which has made the process commercial. In spite of the effort spent on synthetic solutions, no inorganic addition agent has been found which improves the power characteristics of the cell, or affects the product other than forming a slightly smoother deposit.

Temperature Sensitive Paints.—In the *General Electric Review* for February, W. S. ANDREWS gives some condensed data on temperature sensitive paints. He says this term has been applied to chemical compounds that are subject to color changes at a comparatively small rise in temperature. These paints are occasionally used for indicating a dangerous rise in the temperature of machine bearings, electric generators and other apparatus where excessive heating has to be avoided. The two compounds described are easy to make and reliable in operation. The double iodide of mercury and copper is normally red but turns black at about 87 deg. C., becoming red again when the temperature falls. To prepare it make separate solutions of copper sulphate and potassium iodide in distilled water. Add the latter to the former with constant stirring until the precipitate which is first formed is re-dissolved. Then add a strong solution of mercuric chloride (corrosive sublimate) and the red double iodide of mercury and copper will be precipitated. Wash and dry this precipitate on filter paper. The red powder may be mixed with a weak solution of gum arabic in water and used as a paint. The double iodide of mercury and silver is normally of a light primrose yellow, but turns to a dark orange or brick red at about 45 deg. C. It becomes yellow again on cooling—and it may be heated and cooled an unlimited number of times without losing its curious property, providing it is not overheated. To prepare it make separate solutions of silver nitrate and potassium iodide in distilled water. Add the latter to the former with constant stirring until the original precipitate is dissolved. Then add a strong solution of mercuric chloride (corrosive sublimate), which will produce a precipitate of the double iodide of mercury and silver of a bright yellow color. Wash and dry the precipitate on filter paper. It can be used as a paint by mixing with a weak solution of gum arabic in water.

Recent Metallurgical and Chemical Patents

Wood Distillation

Distilling Pyroligneous Acid.—H. O. V. BERGSTRÖM, of Stockholm, Sweden, patents a process of distilling pyroligneous acid under pressure. In the dry distillation of wood or other substance containing cellulose, so-called pyroligneous acid is obtained which principally contains water, acetic acid, wood spirit and tar or tarry constituents dissolved in the pyroligneous acid. The acetic acid is generally recovered in the form of acetate of lime and in order to obtain an acetate containing a high percentage of Ca (OCOCH), the pyroligneous acid is preferably distilled and the distillate is saturated with lime and evaporated. The present invention refers to a method of distilling pyroligneous acid which utilizes the distillation vapors. The charactertistic feature consists in executing the whole process under superatmospheric pressure in the system of apparatus. Consequently, the distillation of the pyroligneous acid is performed under an increased pressure, say 2–4 atmospheres, in the distillation boiler, the vapors formed during the distillation are led also under an increased pressure into lime white or other substance adapted for binding the acid constituents of the same, and the resulting vapors are also held under an increased pressure when utilized for heating purposes, for example for distilling pyroligneous acid, for depriving the same of spirit, for drying the acetate obtained, etc. Another feature of the invention consists in passing the vapors from the distillation of the pyroligneous acid through liquid pyroligneous acid (crude or deprived of spirit) before being led into the lime white or other substance adapted for binding the acid constituents of the same. By this means the tar or tarry constituents are removed from the vapors before they are led into the lime white and a purer acetate is formed.

Another feature of the invention consists in that the vapors, washed with pyroligneous acid or not, instead of being directly led into lime white or the like, are led into a heating element surrounded by acetate solution or other liquid which is to be concentrated. The vapors are condensed in said heating element and the condensate is then saturated with lime or other base for forming acetate solution. In passing through the heating element the vapors give off their heat to the solution, or liquid surrounding the same, the solution being thereby brought to boiling and is, thus, concentrated. The vapors escaping from the boiling solution or liquid may still be maintained under an increased pressure and be utilized for heating purposes as stated above. Another feature consists in using acetate solution instead of water for slaking the lime in order to obtain the lime white necessary for neutralizing the acid constituents of the vapors either in the state of vapors or after having been condensed. (1,261,344 Apr. 2, 1918.)

Dyes and Intermediates

Vat Dyestuffs.—M. P. SCHMIDT, of Biebrich-on-the-Rhine, Germany, patents a process for the manufacture of vat dyestuffs of the carbazole naphtho quinone series. He has found that the carbazole-naphtho-quinones derived from alpha- or beta- naphthylamine still present a similar capacity of condensation as the simple quinones themselves. They give valuable vat dyestuffs of a brown to black tint with the usual compounds containing reactive hydrogen-atoms. Amins, sulphinic-acids, oxythionaphthene, indoxyl or their derivatives and in general all compounds containing reactive hydrogen atoms are suitable for the condensation. It seems that the condensation takes place in the same manner as with naphthoquinones, the element connected with the reactive hydrogen atoms going in orthoposition to one of the quinone-oxygen-atoms, whereby leuco-compounds are produced in the first place with change or may be converted into vat dyestuffs, either by the action of the oxygen of the air or by the employment of other means of oxidation.

They are reddish-brown powders, difficultly soluble in the usual solvents. They may be crystallized from hot glacial acetic acid. With alkaline hydrosulphite they give a yellow vat, from which wool is dyed brown.

24.7 parts of the quinone obtainable from the 1.2-pheno-5-oxynaphthocarbazole are suspended in about 250 parts of water, and 15.6 parts of toluene sulphinic acid are added. The mass is acidified with some hydrochloric acid and heated and stirred on the water-bath for some hours. It is then made alkaline and air is blown through it, until the dyestuff is fully oxidized. The precipitate of a brown color is drained off and washed with water.

The dyestuff yields with alkaline reducing agents a yellow vat, from which wool is dyed with fast brown tints. (1,261,858, Apr. 9, 1918.)

Vat Dyestuffs.—MICHAEL ILJINSKY of Uerdingen-on-the-Rhine, Germany, patents a process of making vat dyes. The invention relates to vat-dyestuffs containing sulphur with an anthraquinone molecule, which are obtained by dry heating of anthraquinone or anthraquinone derivatives with thiosulphates. If for example anthraquinone-sulphonic acids or their salts are heated with thiosulphates, products which can easily be vatted and which take upon cotton in powerful fast tones are formed, while sulphur is liberated. The products of the process mentioned in German Patent 95484 are black sulphur dyestuffs and they are dyed from sodium sulphide solution. The products of the present invention are insoluble in sodium sulphide solution, they are dyed from alkaline hydrosulphite vats and they give olive-colored tints. Also the products resulting from the process described in German Patent 226879 (Example 3) are not identical with those of the present invention. Apart from the difference in color, the dyestuffs prepared according to that specification are all soluble in concentrated sulphuric acid, whereas the new products are insoluble in concentrated sulphuric acid. For the preparation of sulphur dyestuffs, thiosulphates have heretofore many times been employed, but hitherto always in aqueous solutions and with addition of alkali. The present process on the contrary proceeds in the absence of water and alkali, the reacting mixture remaining dry during the whole process. Such thiosulphate melts (if "melts" may in this case be spoken of at all) have not previously been produced. The specification states that it is surprising that under such circumstances the substances enter into reaction. Comparative experiments have demonstrated that for example a mixture of dry sodium anthroquinone-sulphonate, sulphate and sulphur, does not react in a similar manner under the same circumstances. (1,261,394, Apr. 2, 1918.)

Phthalic Anhydride.—THOMAS D. GREENLEY of Glen Ridge, N. J., patents a process of making phthalic anhydride which he assigns to the Ellis-Foster Co., of New Jersey. The process is described as follows:

The first step in the operation is to prepare as an activator or accelerator of reaction a quantity of sulphate of mercury which may be produced by heating and stirring 10 lb. of mercury with 100 lb. of oleum containing 20 per cent SO_3, the temperature being raised to 200 deg. C. and maintained at that point with constant agitation for a period of about one hour. If mercury sulphate is available from other sources or from a preceding run, it is not necessary to prepare the sulphate in this manner. 30 lb. of naphthalene are dissolved in 100 lb. of oleum of the same strength as the foregoing and this solution or mixture is added to the mercury sulphate in acid solution prepared as above set forth. The mixture is heated in a retort to 250 deg. C. and is maintained at this temperature until about one-half of the reaction mass has distilled over. During this heating and distilling operation the reaction mass may be well agitated and to this end the retort is equipped with a stirring device which may be operated so as to give a mild to vigorous agitation, depending upon the size and shape of retort and conditions of operation. In any event, preferably the agitation is carried out in such a manner as to secure a satisfactory intermingling of the reacting constituents. The mass is then cooled to about 200 deg. C. and 100 lb. of oleum are added. The temperature is then raised to about 250 deg., the other conditions being the same as the foregoing. After distillation has been completed to about one-half the volume of the reaction mass, 150 lb. of oleum are added and the temperature carefully raised to about 300 deg. C. The distillate may then be filtered, treated with caustic soda solution and again filtered, the alkaline solution neutralized and evaporated to dryness. To purify, the mass is heated to the subliming point of phthalic anhydride the product is suitably collected and may be purified as desired. (1,261,022, Apr. 2, 1918.)

Refractories

Bonding Kieselguhr Powder.—CHARLES S. KINNISON of Birmingham, England, proposes to bond Kieselguhr so that it may be molded into any desired shape by adding soda-ash solution and drying. Best results are obtained by using 8 to 15 per cent of soda ash and 92 to 85 per cent of Kieselguhr. It is thought that sodium silicate is formed in the drying process. (1,259,525; Mar. 19, 1918.)

Potash

Potash from Kelp.—FRANK K. CAMERON of Salt Lake City, Utah, patents a process of obtaining potash salts from kelp, which he assigns to the Alaska Products Co., of New York. The process comprises mincing and straining the kelp in such a manner as to produce thorough aeration, adding an acid flucculating agent (hydrochloric acid) to produce a floating separation of coagulum from the clear liquor, returning the floating coagulum for treatment together with fresh kelp in the straining operation and evaporating the liquor to crystallization. (1,259,486; Mar. 19, 1918.)

Potash from Leucite Rock.—FRANZ A. RODY of Newark, N. J., patents a process of obtaining potash from silicate rock and other silicates such as leucite, feldspar, etc. The patent is assigned to the Metallurgical Co. of America, of New York. The method comprises fusing about one hundred parts of crude leucite, reducing it to a powder of one hundred mesh and then digesting for about an hour with water and about six parts of lime at a pressure of one hundred pounds per square inch, thereby bringing the alkalis into solution. (1,260,944; Mar. 26, 1918.)

Explosives

Nitro Compounds from Tar Oils.—JOHN R. MARDICK of New York, patents a process of making nitro-compounds from tar oil raw materials containing

several per cent of compounds removable by crystallization and repeated washings, not exceeding three, with 2½ to 5 per cent by weight of sulphuric acid and 5 per cent solution of soda ash, (1) coal tar distillate having a sp.gr. from 1.00 to 1.10 (2) impure water-gas tar distillate having a sp.gr. of 0.95 to 1.08; (3) producer-gas tar distillate having a sp.gr. of 0.95 to 1.08; (4) the first two-thirds of the entire distillate of coal tar; (5) the distillate of a tar or mixture of tar distillates having a sp.gr. between 0.95 to 1.10. The following special nitration process is used as distinguished from the processes customarily employed for nitrating pure benzol, toluol, etc. In operating for example upon coal-tar distillate having a sp.gr. of 1.00 to 1.10 one and one-half parts of an acid mixture consisting of 45 per cent HNO_3, 38 per cent H_2SO_4 and 17 per cent H_2O is used, the acid mixture having a sp.gr. of 1.54 to one part of the aforesaid material, the same being mixed by the gradual addition of the said acid to the oil over a prolonged period of time, preferably about 7 to 8 hours and the temperature of the nitration bath being maintained by means of constant stirring and cooling, during the first two hours between 25 to 30 deg. C., the next three hours between 30 and 35 deg. C. and the last two hours between 35 and 40 deg. C. with the extreme limit preferably 45 deg. C. and in no case above 60 deg. C. After the nitration has been completed, the acid bath beneath the nitro-compounds is withdrawn in the manner customary in the manufacture of tri-nitro-toluene and nitro-glycerin, and the nitro-compound is then drowned in water in the well-known manner by throwing the same into a large volume of water and then thoroughly washing the resultant nitro-product in a suitable vessel with the water maintained at a temperature of about 40 deg. C. The washing operation is preferably repeated about three times. After the washing the nitro-compound obtained is removed to a kneading machine and washed with several changes of water, about three, or until the water shows no substantial acid reaction. Then a small amount of magnesium carbonate is added to neutralize the acid and the material is thoroughly agitated, whereupon it is again washed with water and any soluble crystalline salts are washed out. (1,258,587; Mar. 5, 1918.)

Electrolytic Zinc

Electrolytic Process.—HERBERT R. HANLEY, of Winthrop, Calif., (assigned to Bully Hill Copper Mining and Smelting Co.) patents a zinc extraction process to increase the amount of water-soluble zinc compounds by an acid roast, to remove impurities, and to produce sulphuric acid as a by-product. Sulphide ores should be first roasted to give the maximum amount of sulphates, then this calcine, oxidized zinc ore or fume is mixed with 50 per cent sulphuric acid to form a thick mud (approximately 30 pounds of acid per hundred of ore). The mixture is air dried, then for twelve hours in a flue drier, when the cake is broken to ½ inch and roasted at temperatures ranging from 260 deg. C. at the cold end (200 deg. C. minimum) to 500 deg. C. at the hot end (650 deg. maximum) converting substantially all zinc compounds into water-soluble sulphates, and volatalizing arsenic and selenium. The hot calcine is agitated with water to produce a solution of 1.27 specific gravity and purified in the usual way. An electrolyte preferably containing 120 grams zinc sulphate per liter is then deposited with air agitation until the zinc has fallen to the lowest percentage practicable considering the expense of the current used. The spent electrolyte now contains alkaline and zinc sulphates as well as sulphuric acid and is evaporated to the concentration necessary so it may be added to the beginning of a new cycle. In this process the bulk of the magnesium sulphate will crystalize out, together with a quantity of alkaline sulphates depending upon the amount of zinc remaining in the solution. This sulphate radicle lost is supplied in the primary roast—it may even be necessary to continuously remove an excess of acid so formed. (1,241,966, Oct. 2, 1917.)

Aerating Anode.—Mr. Hanley also patents an aerating device serving also as an anode, illustrated in Fig. 1. The aluminium cathode 2 is suspended between

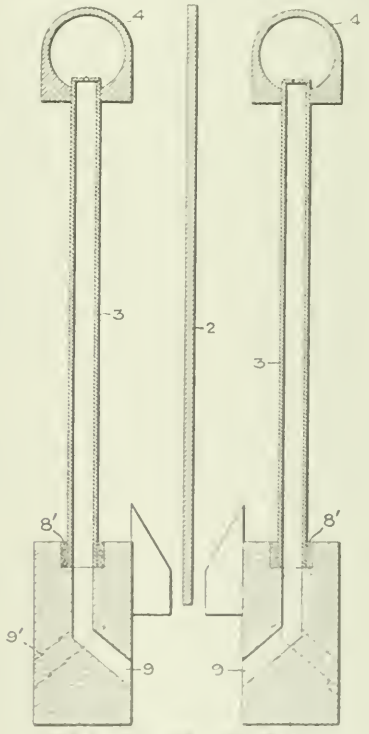

FIG. 1.—COMBINED ANODE AND AERATING DEVICE

a series of lead pipes 3 acting as insoluble anodes. The pipes receive an air supply from a manifold 4 placed above the solution and discharge it at reduced pressure to alternate sides of a nonconducting base 8 fixed across the tank, through openings 9 so large as not to be plugged up by crystals or slimes. The air bubbling up along the face of the cathode brushes off the polarizing hydrogen film, and thus increases the current efficiency. (1,241,967, Oct. 2, 1917.)

Electrodeposition in Strongly Acid Solutions.—U. C. TAINTON and J. N. PRING of England have formerly patented a process (No. 1,059,233) consisting of adding to the zinc solution to be electrolyzed a large percentage of acid and a small proportion of a colloid, and electrolyzing with a current of high density. They now find that some of the advantages of this process can be secured without the colloid, if conditions do not require a smooth and lustrous deposit. A saturated solution of zinc sulphate, for instance, to which was added 16 per cent of sulphuric acid was electrolyzed at a current density of 600 amperes per square foot, obtaining firm deposits with a current efficiency of 94.6 per cent. (1,247,179, Nov. 20, 1917.)

A New Method of Extinguishing Chemical and Oil Fires

The problem of protecting gasoline, oils, chemicals and other inflammable liquids from fire has always been a pressing one. Recently a method of attacking this problem has been devised, which consists in covering the burning surface with "firefoam," which is essentially a carbon dioxide foam very light in specific gravity which floats on the burning surface and snuffs the fire out.

As is generally known it is useless to attempt to extinguish oil, gasoline or chemical fires with water or ordinary fire extinguishers. Water sinks to the bottom of the liquids, or putting it in other words, the burning liquids float on the water and the fire is not extinguished. If extinguishing gases are used they are blown away by the draft of the fire and very little good is accomplished, especially if the fire is of any great magnitude.

This new method of extinguishing fires confines the carbon dioxide gas in a thick, tough blanket of foam, which floats upon the lightest liquids, cutting off the air supply from the fire. The substance is claimed to be quite permanent, lasting an hour or more, which prevents the possibility of the fire reflashing.

The product has been developed by the Erwin Manufacturing Co. of Milwaukee, who have designed special apparatus for applying it so that tanks even 40 or 50 feet or larger in diameter containing inflammable liquids can now be given protection from fire.

Pure Sheet Nickel Now Available for Industrial Purposes

During the past few years there has been a great deal of activity in the promotion of pure nickel and nickel alloys in various forms for manufacturing purposes.

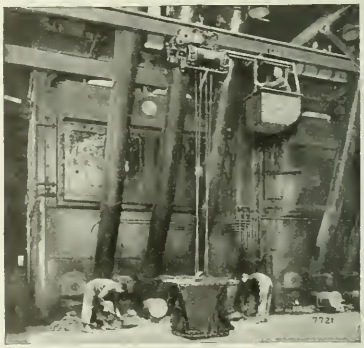
Pure, solid nickel is not the same as the inferior metals usually sold as nickel, such as are used in nickel watch-cases and other manufactured articles which consist mostly of steel, brass or German silver with a thin plating of nickel. This plating wears off in a short time. Pure nickel does not rust or oxidize; it will not tarnish like silver or some of the alloys, such as German silver, and there is no danger of corrosion resulting in the surface being injured as with a plated material. It is not attacked by acids or alkalies in the dilute form, like copper and its alloys, and is practically immune to the attacks of all alkalies regardless of their strength, and is largely resistant to the action of most acids. Nickel also has a very high tensile strength, which is among its chief advantages when used as an acid resisting metal, as there are very few of the other metals which will resist these corroding elements and at the same time have sufficient strength to fit them for many purposes in the chemical field. Pure nickel, when manufactured in the form of sheets, being homogeneous, in addition to its great tensile strength, is very ductile and easily formed by spinning or stamping. Specially formed articles for use in manufacturing chemical equipment can be manufactured from nickel without using any special equipment except that as employed in manufacturing articles from German silver or other hard alloys. Pure nickel tubing is being manufactured and can be supplied in quantities and in all the commercial sizes.

The increase in the cost of copper and its products has brought this to a point where pure nickel can be compared favorably with it as to initial cost. The service and long life of nickel cannot be compared with the common metals.

There are many uses for this metal in the chemical field. Many parts of chemical apparatus require a metal which will withstand the action of corroding elements without deterioration. Facilities for manufacturing pure sheet nickel have been provided for by the Driver-Harris Company, of Harrison, N. J., and for the manufacture of tubing, by the Newark Tube & Metal Works, Newark, N. J.

Handling Ashes with Electric Hoists

The problem of handling ashes mechanically is becoming more urgent, and a mono-rail electric hoist with a bottom dumping bucket has been developed by the Link-Belt Company of Philadelphia, Pa., for this purpose. A photograph of this hoist, in use at the plant of



MONO-RAIL HOIST FOR ASH HANDLING

the Philadelphia Paper Company, is shown in the accompanying drawing.

This machine runs on the lower flange of an I-beam track. It is operated by a man traveling in a trailer cage, who controls the raising or lowering of the bucket, as well as the travel of the hoist. About thirty tons of ashes are handled daily at this plant and are pulled out every six hours.

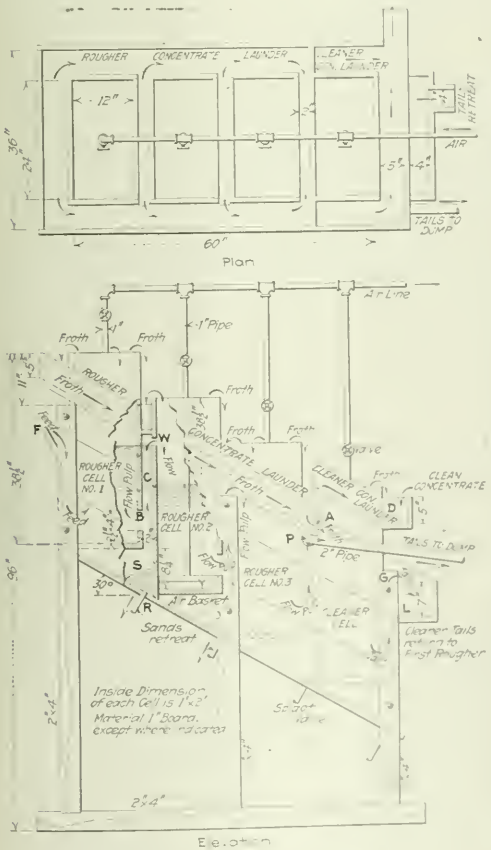
A New Flotation Machine

By A. W. Fahrenwald

THE flotation machine shown in the accompanying illustrations was designed by me for the Texas State School of Mines, to be installed in the testing mill now under construction. To conform with the capacity of the rest of the mill it is designed to treat from 300 to 400 lb. per hr.

The apparatus as shown in the two views consists, in the main, of four cells identical in shape and size. The first three are for roughing and the fourth one for cleaning the concentrates from these. The cells are inclined at an angle of 30 deg. with the horizontal giving a drop of 9½ in. from cell to cell. This drop gives a gravity flow to the pulp in passing through the machine. The distance between cells is 2 in. for this testing machine. For larger capacity in mill work this would be increased somewhat. For large capacity the length of each cell would also be increased to 2½ ft. and the width to 8 to 10 ft. depending upon the tonnage required. The machine is self-contained, which is convenient for testing work. It is easy to operate and requires little attention.

Following the passage of pulp through the machine, the feed enters at the point F, and thence into the rougher cell No. 1. Here the pulp is subjected to the usual pneumatic action where a concentrate froth is formed; this builds up and flows over the four sides of the cell as indicated by the arrows, into a launder which serves the three roughing cells. From roughing cell No. 1 the pulp passes under the baffle B and up the rectangular channel C, between the first and second roughing cells, into roughing cell No. 2. The opening in roughing cell No. 2 controls the height of pulp level in cell No. 1. A similar opening in cell No. 3 controls the pulp level in cell No. 2 and so on through any number of cells. A pipe P for discharging tailings, controls the pulp level in the last roughing cell. The froth overflow from the three roughing cells passes down a common launder into the cleaner cell through the opening A. In this cell a clean concentrate is produced and a tailing overflow at G which is returned to the first roughing cell.



FAHRENWALD FLOTATION MACHINE

The arrangement of cells described is not limited to three cells in series, but three would ordinarily be sufficient. The capacity of the machine can be varied from a very small amount up to the maximum at which point some flotable sulphide would be discharged with the tailings. The operation of the machine is simple and does not require any great amount of care. The only adjustment necessary is that of the air which is accomplished by the use of one main valve. The gate W can also be made adjustable.

In this machine it is possible to treat a feed containing sands. Particles that are too heavy to be carried up the channel C, by the uprising current of pulp, settle down into the pocket S where they can be removed intermittently or continuously through the spigot valve R. For a feed containing sands the first cell would act as a classifier, the sands being sent back to the grinding machine. This opening also affords a way of cleaning out the machine after each test.

The form of bottom used for injecting air into the pulp consists of a top and bottom ribbed casting between which is clamped four thicknesses of canvas. A projection passes up through a hole in the center, connected to a ¼ in. air line. The air is forced underneath the canvas and up through it. There is no leak through the hole in the canvas which fits over the projection since it is clamped between the bottom and top pieces by four bolts at the center in the same way as at the edges.

The machine for testing purposes is self contained; the height of pulp level in each cell is controlled by an opening in the side of the succeeding cell; the froth formed over flows on four sides of each cell, thus giving each particle of concentrate a minimum distance to travel in leaving the machine; the porous bottoms for injecting air into the pulp are lowered into the cells from above and the removal of one for repair does not interfere with the operation of the other cells; it is simple in construction and of low first cost, the pulp passes over a weir the entire width of the machine which gives the individual particles a better chance to be floated than if the same mass of pulp entered the cell through a pipe which overloads the machine in that immediate vicinity.

El Paso, Texas

Automatic Electric Furnace Control

WITH the advent during the past year of 20-ton electric furnaces and indications of an advance to a standard maximum of 30 tons, the General Electric Company developed an improved system of automatic control to handle the motive power necessitated.

These improvements became necessary as the rate of steel production in these furnaces had been increased by the use of higher capacity transformers and higher voltages, which permitted forcing power into the furnaces at considerably higher rates.

The control panel is made in three sections, as shown in Fig. 1. The top section contains three shunt relays and three contractor groups; the total number of each being in accordance with the number of electrodes used. The middle section has three contact-making ammeters each provided with dashpots to prevent hunting, and with coils provided with taps which are used to vary the amount of power supplied to the furnace. Beneath are three small dial switches which are connected to the coil taps. On the lowest section there are four d.p.s.t. knife-blade switches with fuses, one switch being used for the line and the other for the electrode motors.

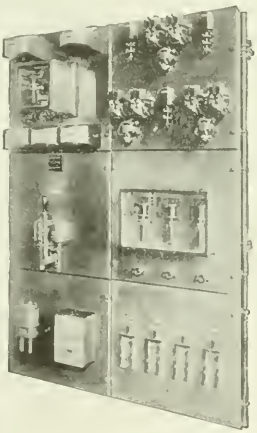


FIG. 1. CONTROL PANEL

Each contactor group consists of three units all mechanically interlocked, two contactors being normally open and one being normally closed.

Facing the panel, the left-hand contactor of any group makes the necessary connections to raise the electrode, while the right-hand contactor causes the electrode to be lowered and the bottom contactor short-circuits the motor armature through a resistance, in this way dynamically braking all moving parts and stopping them almost instantly. A higher resistance is connected in circuit with the armature when lowering than when raising, this being done to keep the speed approximately constant.

The shunt-wound electrode motor is connected to the line until the desired regulation is obtained, when the motor is disconnected and stopped almost instantaneously by means of dynamic braking, this method giving the simplest and most positive control of the electrode movement. The type of motor used was designed for this particular service, especially in regard to self-lubricating bearings, and ranges in size from 1 to 1½ hp. for small equipments, to 5 hp. for 15- to 20-ton furnaces.

The higher power used can be seen by taking for example, the 6-ton furnace, which is the size in greatest general use. The transformer capacity has increased from 900 kv-a. to 1500 kv-a., and even 1800 kv-a. has been proposed, all these capacities being based on 100 volts. In the variable voltage equipments the successful use of 150 volts renders it possible to increase the normal 1500 kv-a. up to 2250 kv-a.

Although 100 volts remains standard for refining, voltages up to 173 have been used for melting, these voltages being obtained either by high-voltage taps or high-voltage Y-data.

Fig. 2 shows a connection diagram of 3-phase furnace arranged for variable voltage operation by means of changing high-voltage connections. The high-melting voltage is obtained by connecting high-voltage windings delta, and the low-refining voltage by connecting them "Y."

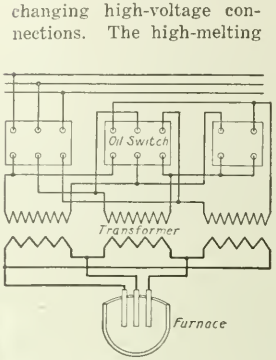

FIG. 2. THREE-PHASE FURNACE ARRANGED FOR VARIABLE VOLTAGE OPERATION

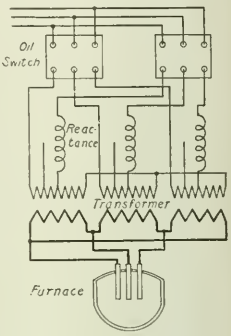

FIG. 3. CONNECTION DIAGRAM OF FURNACE EQUIPMENT USING REACTANCE

When it is considered desirable to use external reactance with high-voltage taps, the method shown in Fig. 3 is used. Variable voltage is obtained by means of high-voltage taps and external reactance is provided to be cut in during the melting period.

The use of high voltages during melting down, permits of decreasing the current for a given input, improves the power factor and insures higher emergency input when most needed.

Book Reviews

TREATISE ON APPLIED ANALYTICAL CHEMISTRY, by Professor *Vittorio Villavecchia*, Director of the Chemical Laboratories of the Italian Customs, translated by *Thomas H. Pope*, B. Sc., A. C. G. I., F. I. C., University of Birmingham. 1918, Vol. I. Price $6.00. 476 pages and 58 illustrations. Philadelphia: P. Blakiston's Son & Co.

One picks up this volume expecting to find a treatise on methods of separation as well as the customary opening chapters on weighing, filtering, igniting, etc.; but one is surprised to find that it is a compendium of analytical and other tests of economically occurring substances. The capitulation is by name of material or class. Chemical products are treated individually and in alphabetical order. Then follow chapters on classes of substances and materials such as fertilizers, cement materials, metals, fuels, coal-tar, oils and fats. Even stable manure has a place as a complex fertilizer. Asphalt appears to be overlooked; rubber, paints and glass likewise. There is much material of a non-analytical or non-chemical text throughout as a consequence of this method, resulting in chapters or paragraphs on such subjects as technical tests of cement and

photometric tests of illuminating oils. There are tests described for the thoroughness of metallic coatings, gilding, silver and nickel plating, oxidizing, etc. The translator's work is excellent, but at times his art is not concealed. Thus "newly won" in the following sentence, "When newly won, lignites contain 20-60% moisture" may be good rendering of a happy Italian phrase, but in English it is not colloquially technical or technically colloquial. As a whole the work is extremely valuable for its full compilation of specific tests and criteria, standards and requirements for commercial purity of industrial chemical substances.

ELECTRIC FURNACES IN THE IRON AND STEEL INDUSTRY. By *Rodenhauser* and *Schoenawa*. Translated from the German by *C. H. Vom Baur*. Second edition, octavo (14 x 22 cm.), xviii + 429 pages, 135 illustrations. Price $3.75. New York: John Wiley & Sons. London: Chapman & Hall, Ltd.

The first edition of this noteworthy book, appearing in 1913, made its mark, and was duly reviewed by us. This new edition has been largely re-written, and much new material added to keep pace with the developments of the last four years. We would like to have seen a fuller description given of the Heroult furnace, since it is the one in largest use, and more complete directions as to using burned dolomite instead of burned magnesite in making up furnace hearths, since the former is more sensitive to impurities than the latter, and account should be taken of that fact. Yet, there is no other book in English which covers this ground so thoroughly and satisfactorily; it is invaluable to the iron and steel metallurgist, and highly instructive to all using or interested in electric furnaces.

* * *

LUBRICATING ENGINEERS' HANDBOOK. By *John Rome Battle*. 334 pages. Illustrated. Price, $4.00. Philadelphia: J. B. Lippincott Company.

The author of this book has produced a very commendable work, both in the theory and practical application of lubricants, and the book should appeal to those interested in lubrication in general.

Considerable extraneous information is included in the book, which is more of a mechanical engineering than of a lubricating nature, and many pages have been covered with matter of a purely descriptive nature regarding various machines, their moving parts, and other apparatus used in the industrial arts. Such miscellaneous information as has been included can be found in most good books on mechanical engineering and it appears somewhat out of place in a book devoted to lubrication. Almost every kind of a machine and apparatus requiring lubrication has been described along with the principles of their lubrication. Very little literature pertaining to lubricating oils and their application has been written; consequently for those seeking general information on this subject the book should prove of interest. As a reference work, however, the book would not appear to be very useful, as the subject matter is too general in nature. The book is well written in language understandable by the layman, and the subject matter is arranged in logical sequence; the type is large and easily read, on good paper, and the illustrations are numerous.

* * *

HYDRO-ELECTRIC POWER STATIONS. By *Eric A. Lof* and *David Rushmore*. Price $6.00. New York: John Wiley & Sons, Inc.

A timely interest attaches to any book on this subject owing to the impending reawakening of hydro-electric development. The present treatise gives an outline of current practice in the various phases of engineering involved. The authors claim that "this book deals with and explains the problems which must be solved in connection with the construction and management of a hydro-electric power station, so that the manager or engineer may select power equipment and fully understand the economic factors which enter into each individual situation." Unfortunately the book does not do this in as large a measure as could be desired. The discussion of the fundamental problems involved is too meagre and too much wanting in critical quality to be much of a guide either to the student or the engineer. On the other hand the book furnishes a fairly complete picture of standard practice at the present time, particularly in regard to the electrical portion of the subject. It is in this phase that the authors of course are chiefly interested; and this probably accounts for the fact that about 300 pages of the book have been devoted to matters concerning electric generation, transformation, transmission, etc., that are in no way peculiar to hydro-electric power generation. The dearth of books on this subject impels us to admit, however, that we know of no more satisfactory treatise; and for a really satisfactory one we shall probably have to wait until the subject is tackled by some engineer whose experience on the anterior side of the turbine coupling is equivalent to that of the authors on the posterior side—and that may be a long while.

THE JOURNAL OF THE INSTITUTE OF METALS, Vol. XVIII. Edited by *G. Shaw Scott*, 21 -net. The Institute of Metals, 36, Victoria Street, London.

There is continued in the present volume the invaluable discussion on metal melting that was inaugurated by the institute last year. A new system of gas-firing is described which is claimed to enable metals to be melted exceedingly economically and which effects great savings in coal. The possibilities of using powdered coal for brass melting are fully discussed by numerous fuel experts.

Though brass is so important for war work and so much space is devoted to its consideration in the *Journal*—notably in the case of Dr. Parker Haigh's article "Experiments on the Fatigue of Brasses"—other of the non-ferrous metals and alloys that the Institute of Metals exists to study receive attention. Thus we find Professor H. C. H. Carpenter, who is to be this year's president of the institute, contributing a valuable paper, jointly with Lieut. L. Taverner, on the effects of heat on aluminium sheet. Other metallurgical problems discussed relate to high temperature thermostats, the effect of hydrostatic pressure on metals, and etching re-agents. A valuable treatise is given by Professor T. Turner, on "Hardness and Hardening," in which the latest views upon this subject are ably summarized and discussed.

Engineers will be specially interested in Professor W. E. Dalby's full and completely illustrated account of the researches that he has made with the aid of his remarkable "autographic load-extension optical indicator."

The volume under review concludes with a section in which concise abstracts are given of all recent literature bearing on metals.

EYE HAZARDS IN INDUSTRIAL OCCUPATIONS. By *Gordon L. Berry*, Field Secretary, National Committee for the Prevention of Blindness, with the co-operation of Lieut. Thomas P. Bradshaw, U. S. Army, formerly Technical Assistant to the Director of the American Museum of Safety. (Octavo, 150 pp., illus.) Published by the National Committee for the Prevention of Blindness, 130 East Twenty-second Street, New York. Price, 50 cents.

In this volume the author reviews the chief industrial hazards to eyesight in the industries of the United States. Case reports illustrate each section, the special dangers are described and recommendations made for such changes of working conditions, or installations of protective devices, as have been found suitable for protecting workers. The book is most completely illustrated.

The following section headings indicate the scope of the book: Statistics of Eye Accidents, Chipping Operations, Machine Operations, Abrasive Wheels, Sand-Blasting, "Mushroomed" Tools, Riveting, Radiations from Intense Light and Heat Sources, Ultra-violet Rays in Illuminants, Radiant Energy in Arc Welding and in Molten Metal, Metallurgical Operations, Glassblowers' Cataract, Infections, Gage Glasses, Acids and Chemicals, Treatment of Acid

Burns, Industrial Poisons, Removal of Dangerous Fumes, Vapors and Gases, Spray Process Hazards, Methyl Alcohol, Bottling Accidents, Mining and Quarrying, Agricultural Hazards, Goggles, Garment Trade Hazards, Industrial Lighting, the Safety Movement.

These subjects have been treated not so much in the way of a technical manual for safety engineers, but rather in a general informative way for the information of the average manufacturer or layman who is seeking information of this nature. Descriptions of many of these hazards have been included heretofore in publications covering the complete field of industrial accident prevention, and where discussion of preventive measures would be repetition the author has referred his reader to the chief of those sources where such detailed information might be secured, if desired.

Much of the "laboratory work" in the preparation of this book was accomplished in Buffalo, New York, where at the invitation of a large group of leading citizens a study was made of the eye hazards and methods in vogue for accident prevention in representative industries of that typical manufacturing city.

The book is the most complete compilation of material relating solely to the prevention of eye accidents that has been published in this country. Inasmuch as there occur annually in the United States alone nearly 200,000 eye accidents, from which many cases of total blindness result, it would seem that there is need for further attention to this important subject.

Personal

Mr. R. C. Bergen, assistant editor of Metallurgical and Chemical Engineering, has resigned to go into chemical manufacturing work. He has been connected with this journal since its change to a semi-monthly in 1915 and was formerly chemical engineer with the Roessler & Hasslacher Chemical Co., at Perth Amboy, N. J.

Mr. Charles Philip Coleman has been elected president of the Worthington Pump and Machinery Corporation. Mr. Coleman advances from the position of vice president, held since May, 1916, to the presidency. He was, prior to that date, receiver of the International Steam Pump Company and associate companies, which have now been reorganized into the present corporation, which owns and controls large works manufacturing pumping machinery and affiliated lines.

Mr. Francis C. Frary, research chemist of the Aluminum Company of America, has been commissioned as captain in the ordnance reserve corps and assigned to research work in the trench warfare section, Engineering Bureau, office of the Chief of Ordnance, Washington, D. C.

Mr. H. E. Ives, formerly with the United Gas Improvement Company, Philadelphia, Pa., has entered the science and research division of the United States signal corps and is now stationed in Washington.

Mr. Henry H. Mandle has resigned from his position as chief of the technical staff of Herman & Herman, Inc., and has reverted to his former practice as a consulting chemical engineer with offices at 220 West 42d St., New York. Mr. Mandle has also become interested in the National Bronze & Chemical Works, for whom he is acting in the capacity of technical adviser.

Mr. Louis S. Munson, associated with the Ault & Wiborg Company, Cincinnati, O., for the past eleven years in the capacity of chemist, has resigned to take charge of the production department of the new dye plant being erected by the du Pont's on the Delaware River near Wilmington.

Dr. J. C. Olsen has accepted the position of Professor of Chemical Engineering and Head of that department at the Polytechnic Institute of Brooklyn. A new chemical engineering laboratory is to be equipped and installed at the Polytechnic Institute, and more emphasis given to the course in Chemical Engineering, both day and evening. Considerable more space is available for the work in Chemistry since the Institute has taken over the building used by the Preparatory Department. This building has been thoroughly overhauled and put in first-class condition. New chemical laboratories will be built in this building.

Mr. Charles M. Schwab, chairman of the Board of Directors of the Bethlehem Steel Corporation and president of the Bethlehem Shipbuilding Corporation, has been made Director General of the Emergency Fleet Corporation. He will devote all of his time to "speeding up" shipbuilding and has arranged to have the offices of the Fleet Corporation removed to Philadelphia, which is the center of shipbuilding in the East. He will have no connection with the letting of contracts.

Mr. E. Gybbon Spilsbury has returned from Cuba, where for the last two months he has been studying the manganese situation.

Mr. A. E. Ward has been appointed sales manager of the International Oxygen Co., 115 Broadway, New York. Mr. Ward was formerly with the Prest-O-Lite Company and for many years has been associated with the compressed gas industries.

Current Market Reports

The Iron and Steel Market

The chief development of the past fortnight in the iron and steel situation has been a clear realization that the war requirements in steel are greater, in proportion to productive ability, than had been estimated. The steel makers find occasion to consider more seriously the matter of supplying adequately all the war activities, and particularly that of shipbuilding, than they had previously felt was necessary.

There have been some misunderstandings, which have been ironed out, and the steel makers are simply addressing themselves more strenuously to the task. It appears that the work of shipbuilding is accelerating more rapidly than was previously apparent. The vessel launchings of late, of which there have been precise statistics, are not a measure of the work that is proceeding. In other words, steel is being fabricated at the shops tributary to the shipyards at such a rate as to presage in due course a much heavier rate of vessel launchings, and vessel completion, than has obtained in the past few weeks.

The requirements in steel for our allies have visibly increased. It appears that some requirements were withheld from trade knowledge. In the past two or three weeks the trade has learned, for instance, that according to trustworthy reports General Pershing quietly borrowed from Britain and France steel in various forms representing a total of over 700,000 tons, and this steel General Pershing merely notified the Government it would have to find in the United States and ship abroad, to repay the loan. Of this particular amount 300,000 tons is to be in ship plates for British yards, while there are other and direct requirements in the same quarter.

From all that can be learned there is occasion to expect that iron and steel exports to our allies for the remainder of the year will be at a materially greater rate than has obtained in the past few months. This has a double influence upon the steel trade, for there is not only the increase in exports to be reckoned, but also the fact that exports in recent months have been made up rather largely of steel that had been accumulating for a long period on the Atlantic seaboard. Lately the shipments from mills, for export, have been much less than the tonnage actually leaving the country.

With these new developments it appears that a larger amount of steel will be required for prosecuting the war than was represented by the appraisals current at the beginning of April. With production unchanged from anticipations, the supply of steel remaining for purely commercial purposes, not connected with the war, will be less than had been expected.

The iron and steel market has given concrete testimony to the situation now confronting the trade. Since about

the first of March shipments of pig iron and of finished steel products to commercial consumers have been much greater than in the first two months of the year, probably at least twice as great. In some quarters it was thought that such an increase would soon result in commercial consumers being fully supplied. Their requirements are, of course, much less than before the country became as fully engaged in prosecuting war as it now is. On the other hand, it is quite certain that the requirements have increased over those of early in the year, when consumers were hampered in their operations, just as producers were.

There has been no material increase in production in April as compared with March. The output of pig iron has been larger, but there has hardly been a commensurate increase in the production of steel. Shortage of scrap is distinctly in evidence. The mills must now depend chiefly upon their own scrap and such as is obtained from industrial consumers engaged in war work. The usual flow of old material into consumption is quite generally arrested, as there is little new construction of a character that would displace old material, whether in industrial or municipal operations, or in the railroad field.

The restriction to blast furnace operations in the central west through insufficient car supplies in the Connellsville region has been fully as great in April as in March, when there was a noteworthy improvement over conditions in January and February. The furnaces dependent upon by-product coke now have practically full operation, and in occasional instances furnaces formerly dependent entirely upon Connellsville coke have been able to secure by-product coke, a surplus over the producer's own requirements. For a complete solution of the coke situation in the central west the completion of additional by-product ovens may perhaps have to be awaited. Ovens with a capacity of about 100,000 tons of coke a week are scheduled for completion within a few months.

On the whole, operations in the iron and steel industry have been at the rate of about 85 per cent of capacity in the past two months, with no great changes from week to week. The output is approximately equal to the average output in 1916, but the capacity, by reason of new construction, is much larger. The tonnage that represented full operation in 1916 now represents an average of about 85 per cent operation. In view of the great decrease that has occurred in the commercial, or peace, consumption of steel since 1916, it is obvious that an enormous tonnage is released, voluntarily or otherwise, for prosecuting the war.

The markets have been very quiet. Nearly all shipments are in connection with war operations, or against old commitments by ordinary consumers, whose deliveries have been greatly delayed. Throughout the market prices are at the prescribed maximum limits.

Non-Ferrous Metal Market

Monday, April 22.—There is nothing much to report in copper and tin. Lead and spelter continue weak. The price of nickel has been fixed by agreement. Antimony is unchanged.

Copper.—Consumers have been able to obtain sufficient supplies for their purposes and as the refinery production is increasing there is no sign of any copper shortage. The price remains as fixed by the Government at 23½c. per pound for producers and 24.67½c. per pound for jobbers.

Tin.—New business in tin is practically at a standstill as Chinese tin is held at a very high price and other brands are off the market. Australian tin for future delivery has appeared on the market at about 85½c. for June shipment. Arrivals at Atlantic ports up to April 17 were only 420 tons, mostly from the United Kingdom.

Lead.—The trust price was reduced to 7c. on Apr. 11, the actual market having been under that of the trust for some time. The market is quiet with principal producers asking 7c. New York and 6.92½c. E. St. Louis. Independents ask 7⅛ to 7¼c. New York.

Spelter.—The market continues dull with commercial spelter at 6.92½c. New York and 6.75-6.80 E. St. Louis for spot lots. May delivery at New York is quoted at 6.92½-7.02½, June at 5c. higher, and July at 5c. higher than June.

Nickel.—An agreement has been reached between the International Nickel Co., Bernard M. Baruch and the Council of National Defense, by which high-grade nickel will be sold at 40c. and the lowest grades at 38c.

Antimony.—Now quoted at 12¼ to 12½c. per pound. There are more sellers than buyers and futures are not interesting to the former, the spot market commanding most of the attention.

OTHER METALS

Aluminium, lb., 98-99 per cent, virgin, Gov't price	.32
Bismuth, lb.	2.50-2.75

Quicksilver, Mexican	118.00

Chemical Market

COAL TAR PRODUCTS: The situation underwent but little change during the interval. Some of the important crudes like benzol were in better demand, but supplies are so liberal that chemical prices are inclined downward rather than otherwise. The intermediates in general were in fair demand and prices are inclined to firm up somewhat due to restricted offerings.

Benzol: A slight improvement is reported in the buying demand, and some fairly good size contracts were closed over the year. The increase in demand, however, is not great enough to absorb the large quantities on the market and the position is very weak. It is said that sales were made at a reduction in price, where a large quantity was involved.

Phenol: There are more offerings of this material than for some time heretofore. The demand is only routine and prices are easier.

Toluol: The government has released some fairly large quantities of late to the manufacturers of dye intermediates, but there is not a great deal available. Producers are not in a position to offer except with permission by the government. Second hands are taking advantage of the situation and are exacting all sorts of prices for the small quantities on hand.

Naphthalene: Offerings are not liberal, but the demand is so light that the position is weak, though prices are quotably unchanged.

Aniline Oil: The demand has been active and second hands are pretty well cleaned out, although small scattered offerings tend to keep prices at present levels.

Aniline Salts: There has been an active export demand of late and prices have firmed up as a result. There is little or no material in second hands, so that producers are realizing their own prices.

Beta Naphthol: The technical material is in steady demand, but the production is heavy and prices are unchanged.

Para Toluidine: Although the stringency in the toluol situation has caused some producers to curtail, there is no change in price as the demand is not particularly heavy.

Sulphanilic Acid: The production is confined to a few quarters. The demand is not heavy and prices are therefore unchanged.

Phthalic Anhydride: Competition between some of the large factors has caused a drop in price; there is a fair demand.

Benzidine Base: There is a fairly active demand, but there is an ample production and prices are unchanged.

Benzaldehyde: There are only a few concerns producing this material at present; this fact coupled with the scarcity and high prices of toluol tends to drive prices upward.

Monochlorbenzol: Large quantities of this material have backed up on the market with practically no demand; a very favorable price can be done.

HEAVY CHEMICALS: Trading generally has been comparatively quiet and the volume of business has been rather disappointing. As a rule the tendency of values has been downward with the exception of special items which are extremely scarce and for which there is a very heavy demand.

Caustic Soda: The market during the past two weeks has been rather listless but has been featured by a strong market for future deliveries and a rather easier position for spot stocks. Producers have had the situation well in hand and from 5c. to 5½c. has been quoted for shipments from plant basis works freight. Spot cars have sold at from 4.50 up to 5c. Sales at the former figure have been principally due to the fact that there has been a lack of buying inquiry for these cars and the holders have in some instances been pressed for cash. A few producers have named prices for 1919 but these have been on such a high level that consumers have naturally shown but little tendency to cover. Buyers seem to feel that the new prices have been named merely to feel out the market.

Soda Ash: A lack of consuming demand and increased shipments have tended to ease off an easy situation. Barrels were for the most part rather firm but at the moment of writing have eased off and are obtainable at 2.85 spot New York. Bags have been very weak and have been quoted as low as 2.40 Philadelphia and 2.50 New York.

Bichromate of Soda: The market has not been subject to marked change during the interval but has been subject to fluctuation practically daily. Considerable speculation is still rife despite the fact that large losses have been the rule in the past in transactions of this sort. Sales of spot have occurred between 21c. and 22c. with the market occasionally up to 23c. As a rule small lots have sold at lower prices than car quantities.

Acetic Acid: This product has been one of the features of the chemical market. As has been the rule when the government assumed control of industry, prices have soared skyward with supplies almost impossible to be obtained. Producers have been disposing of production to certain approved buyers but for outside business the 20% material has sold as high as 15c. Some 56% material is held at 23c. Glacial has sold at 37c. and 38c., with sellers asking 40c. and even more.

Cyanide of Soda: While the regular trade has been asking 40c. and 42c. there have been resales from time to time at prices ranging from 38c. upward. On contract producer quotes 37c. for the soda and 32c. for the mixture for regular consumers only.

Copper Sulphate: A lack of consuming demand has resulted in practically no important business of late and resale lots have been on the market from time to time at prices ranging from 8.80 to 9.10. The regular trade has quoted from 9.25 to 9.50.

Sulphuric Acid: The production seems to have overcome the demand somewhat and acid has backed up on some manufacturers with the result that offers of sixty-six brimstone acid have been made at $35.00 sellers tanks works. The sixty degree brimstone acid has been available at $25.00 sellers tanks works. Resale lots of sixty-six acid have changed hands as low as at $32.50 New Jersey point.

Oleum: This situation has also been somewhat easier. Twenty per cent material has been rather difficult to move at $65.00 tanks and $70.00 drums, although there has not been a great deal of material offered on the open market. Sixty per cent oleum is being produced in a limited way and sales have occurred at $225 per ton.

Nitric Acid: Some acid not water white probably aqua fortis is being offered at 8¾c. works but for prime white material producers will not shade 9c. and there are makers who are holding to as high as 9.60 for the 42 degree material.

Muriatic Acid: The situation has been firm and twenty degree material is held firmly at 2¼c. as a minimum trading level at works. Offers of the 22 degree material are more restricted as the warm weather approaches and while some acid has been available at 2.50 works, generally 2¾c. and even 3c. has been obtained for moderate quantities. Carboys continue scarce and restrict the movement in all acids to a noticeable extent.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, APRIL 23, 1918

Acetic anhydride	lb.	1.35 — 1.50
Acetone, drums	lb.	Nominal
Acid, acetic, 28 per cent	lb.	Nominal
Acetic, 56 per cent	lb.	Nominal
Acetic, glacial, 99½ per cent., carboys	lb.	.40 — .41
Boric, crystals	lb.	.13¼ — .14½
Citric, crystals	lb.	.87 — .88
Hydrochloric, C. P	lb.	Nominal
Hydrochloric, 20 deg	lb.	.02½ — .02¾
Hydrochloric, conc., 22 deg	lb.	.02½ — .03
Hydrofluoric, 30 per cent., in barrels	lb.	.06 — .06½
Lactic, 44 per cent	lb.	.15½ — .16
Lactic, 22 per cent	lb.	.06 — .06½
Molybdic, 85 per cent	lb.	3.85 — ...
Nitric, 36 deg	lb.	.08¼ — .08½
Nitric, 42 deg	lb.	.09 — .10
Oxalic, crystals	lb.	.43 — .45
Phosphoric, 47–50 per cent. paste	lb.	.08 — .10
Phosphoric, ref. 50 per cent	lb.	.26 — ...
Picric	lb.	Nominal
Pyrogallic, resublimed	lb.	3.10 — 3.15
Sulphuric, 60 deg	ton	25.00 — 27.50
Sulphuric, 66 deg	ton	35.00 — 40.00
Sulphuric, oleum (Fuming), tank cars	ton	60.00 — 75.00
Tannic, U. S. P., bulk	lb.	1.30 — 1.35
Tartaric, crystals	lb.	.75 — .78
Tungstic, per lb. of W	lb.	1.70 — 1.75
Alcohol, sugar cane, 188 proof	gal.	4.93 — 4.95
Alcohol, wood, 95 per cent	gal.	.90½ — .91
Alcohol, denatured, 180 proof	gal.	.68 — .69
Alum, ammonia lump	lb.	.04 — .04½
Alum, chrome ammonium	lb.	.18 — .19
Alum, chrome potassium	lb.	.20 — .21
Alum, chrome sodium	lb.	.12½ — .13
Alum, potash lump	lb.	.08½ — .09
Aluminium sulphate, technical	lb.	.02½ — .02
Aluminium sulphate, iron free	lb.	.03½ — .03½
Ammonia aqua, 26 deg. carboys	lb.	.25 — .26
Ammonia, anhydrous	lb.	Nominal
Ammonium carbonate	lb.	Nominal
Ammonium nitrate	ton	(Fixed price) .15
Ammonium, sulphate domestic	lb.	.07½ — .08
Amyl acetate	gal.	5.00 — 5.25
Arsenic, white	lb.	.17 — .18
Arsenic, red	lb.	.65 — .70
Barium carbonate, 99 per cent	ton	80.00 — 90.00
Barium carbonate, 97–98 per cent	ton	65.00 — 67.00
Barium chloride	ton	65.00 — 85.00
Barium sulphate (Blanc Fixe, Dry)	lb.	.02½ — .02¾
Barium nitrate	lb.	.09½ — .10
Barium peroxide, basis 70 per cent	lb.	.30 — .32
Bleaching powder, 35 per cent. chlorine	lb.	.02 — .02½
Borax, crystals, sacks	lb.	.07½ — .08½
Brimstone, crude	ton	Nominal
Bromine, technical	lb.	.75 — ...
Calcium, acetate, crude	lb.	Nominal
Calcium, carbide	lb.	12½ — .13
Calcium chloride, 70–75 per cent., fused, lump	ton	27.50 — 30.00
Calcium peroxide	lb.	1.60 — 1.70
Calcium phosphate	lb.	.34 — .35
Calcium sulphate 98–99 per cent	lb.	.09 — .09½
Carbon bisulphide	lb.	.08¼ — .10
Carbon tetrachloride, drums	lb.	.15½ — .16
Carbonyl chloride (phosgene)	lb.	1.10 — 1.50
Caustic potash, 88–92 per cent	lb.	.83½ — .84
Caustic soda, 76 per cent	lb.	.048 — .05
Chlorine, liquid	lb.	.15 — .18
Cobalt oxide	lb.	1.60 — 1.65
Copperas	lb.	.01¼ — .01½
Copper carbonate	lb.	.30 — .40
Copper cyanide	lb.	75 — .78
Copper sulphate, 99 per cent., large crystals	lb.	.09 — .09¼
Cream of tartar, crystals	lb.	.63 — .65
Epsom salt, bags, U.S.P	lb.	.03¼ — .03¾
Formaldehyde, 40 per cent	lb.	.19 — .19½
Glauber's salt	100 lb.	1.50 — 2.00
Glycerine, bulk, C. P	lb.	.66 — .67½
Iodine, resublimed	lb.	4.25 — 4.35
Iron oxide	lb.	.13 — .15
Lead, acetate, white crystals	lb.	.17 — .18
Lead, arsenate (Paste)	lb.	.15 — .18
Lead nitrate	lb.	.15 — .16
Litharge, American	lb.	.09½ — .11½
Lithium carbonate	lb.	1.50 — 2.00
Manganese dioxide, U. S. P	lb.	.70 — .75
Magnesium carbonate, technical	lb.	.10½ — .11
Nickel salt, single	lb.	.14 — .15
Nickel salt, double	lb.	.12 — .14
Phosgene, see Carbonyl chloride		... — ...
Phosphorus, red	lb.	1.30 — 1.50
Phosphorus, yellow	lb.	1.50 — 1.60
Potassium bichromate	lb.	.44 — .46
Potassium bromide granular	lb.	1.35 — 1.50
Potassium carbonate calcined, 85–90 per cent	lb.	.55 — .60
Potassium chlorate, crystals	lb.	.36 — .40
Potassium cyanide, 98–99 per cent	lb.	Nominal
Potassium iodide	lb.	3.75 — 3.80
Potassium muriate 80–85 p. c. basis of 80 p. c.	ton	325.00 — 350.00
Potassium nitrate	lb.	.27 — .31
Potassium permanganate (U. S. P.)	lb.	3.80 — 4.00
Potassium prussiate, red	lb.	2.80 — 2.90
Potassium prussiate, yellow	lb.	1.18 — 1.25
Potassium sulphate, 90–95 p. c. basis 90 p. c.	ton	Nominal
Rochelle salts	lb.	.41 — .42
Salammoniac, gray gran	lb.	.17 — .18
Salammoniac, white gran	lb.	.15¾ — .16
Sal soda	100 lb.	1.35 — 1.40
Salt cake	ton	24.00 — 27.00
Silver cyanide, based on market price of silver	oz.	... — ...
Silver nitrate	oz.	.61½ — .62
Soda ash, 58 per cent., light, flat (bags)	100 lb.	2.50 — 2.60

Soda ash, 58 per cent., dense, flat	100 lb.	3 75	—	
Sodium acetate	lb.	23	—	.24
Sodium bicarbonate, domestic	lb.	.02½	—	03
Sodium bicarbonate, English	lb.		—	
Sodium bichromate	lb.	.22½	—	23
Sodium bisulphite, powd	lb.	.05½	—	06
Sodium chlorate	lb.	.24	—	.25
Sodium cyanide	lb.	.38	—	40
Sodium fluoride, commercial	lb.	.18	—	19
Sodium hyposulphite	lb.	.02½	—	02½
Sodium molybdate, per lb. of Mo	lb.	2 50	—	
Sodium nitrate, 95 per cent	100 lb.	Nominal		
Sodium nitrate	lb.	.33	—	34
Sodium peroxide	lb.	.45	—	.50
Sodium phosphate	lb.	.04	—	.05
Sodium prussiate, yellow	lb.	.41½	—	.42
Sodium silicate, liquid (60 deg.)	lb.	Nominal		
Sodium sulphide, 30 per cent., crystals	lb.	.02¼	—	.03
Sodium sulphide, 60 per cent., fused	lb.	.05¼	—	.06
Sodium sulphite	lb.	Nominal		
Strontium nitrate	lb.	.25	—	35
Sulphur chloride, drums	lb.	06	—	.06½
Sulphur dioxide, liquid, in cylinders	lb.	15	—	40
Sulphur, flowers, sublimed	100 lb.	4 05	—	4 60
Sulphur, roll	100 lb.	3 70	—	3 85
Sulphur, crude	ton	Nominal		
Tin bichloride, 50 deg	lb.	.23½	—	24½
Tin oxide	lb.	.78	—	.80
Zinc carbonate	lb.	25	—	30
Zinc chloride	lb.	.12½	—	.13
Zinc cyanide	lb.	Nominal		
Zinc dust, 350 mesh	lb.	.14	—	.16
Zinc oxide, American process XX	lb.	.14	—	.15
Zinc sulphate	lb.	.05	—	.06

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.30	—	.35
Benzol, 90 per cent	gal.		—	
Toluol, pure, water white	gal.	Nominal		
Xylol, pure, water white	gal.	.35	—	.50
Solvent naphtha, water white	gal.	.17	—	.22
Solvent naphtha, crude, heavy	gal	.13	—	.16
Creosote oil, 25 per cent	gal.	.33	—	.35
Dip oil, 20 per cent	gal.	.29	—	.30
Pitch, various grades	ton	8 00	—	20 00
Carbolic acid, crude, 95-97 per cent	lb.	1 05	—	1 10
Carbolic acid, crude, 50 per cent	lb.	.60	—	.65
Carbolic acid, crude, 25 per cent	lb.	.35	—	.38
Cresol, U. S. P.	lb.	.18	—	.20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1 00	—	1 25
Alpha naphthol, distilled	lb.	1 60	—	2 00
Alpha naphthylamine	lb.	.58	—	.60
Aniline oil, drums extra	lb.	.25½	—	.27
Aniline salts	lb.	.32	—	.34
Anthracene, 80 per cent	lb.	.50	—	.65
Benzaldehyde (f.f.c.)	lb.	5 25	—	5 50
Benzidine, base	lb.	1 75	—	1 85
Benzidine, sulphate	lb.	1 40	—	1 50
Benzoic acid U. S. P.	lb.	4 25	—	4 50
Benzoate of Soda, U. S. P.	lb.	4 00	—	4 25
Benzyl chloride	lb.	2 25	—	2 50
Beta naphthol benzoate	lb.	10 00	—	12 00
Beta naphthol, sublimed	lb.	.85	—	.90
Beta naphthylamine, sublimed	lb.	2 65	—	
Dichlor benzol	lb.	.12	—	.18
Diethylaniline	lb.	4 50	—	5 00
Dinitro benzol	lb.	.35	—	.40
Dinitrochlorbenzol	lb.	.40	—	.42
Dinitronaphthaline	lb.	.55	—	.60
Dinitrotoluol	lb.	.55	—	.60
Dinitrophenol	lb.	.46	—	.50
Dimethylaniline	lb.	.65	—	.70
Diphenylamine	lb.	1 00	—	1 10
H-acid	lb.	2 25	—	2 50
Metaphenylenediamine	lb.	2 00	—	2 25
Monochlorbenzol	lb.	.17	—	.19
Naphthalene, flake	lb.	.10½	—	.10¾
Naphthalene, balls	lb.	.12	—	.13
Naphthionic acid, crude	lb.	1 20	—	1 30
Naphthylamin-di-sulphonic acid	lb.	1 00	—	1 10
Nitro naphthaline	lb.	.45	—	.50
Nitro toluol	lb.	.50	—	.55
Ortho-amidophenol	lb.		—	
Ortho-dichlor-benzol	lb.	.15	—	.18
Ortho-toluidine	lb.	1 25	—	1 30
Ortho-nitro-toluol	lb.	.75	—	1 00
Para-amidophenol, base	lb.	3 50	—	3 75
Para-amido-phenol, H. Cl	lb.	4 00	—	5 00
Para-dichlor-benzol	lb.	.12	—	.15
Paranitraniline	lb.	1 25	—	1 30
Para-nitro-toluol	lb.	1 50	—	1 60
Paraphenylenediamine (base)	lb.	3 00	—	3 25
Para toluidine	lb.	2 25	—	2 50
Phthalic acid anhydride	lb.	3 50	—	4 00
Phenol, U. S. P.	lb.	.52	—	.54
Resorcin, technical	lb.	5 75	—	6 00
Resorcin, pure	lb.	8 50	—	9 00
Salicylic acid	lb.	.95	—	1 00
Salol	lb.	1 90	—	2 00
Sulphanilic acid, crude	lb.	.32	—	.35
Tolidin	lb.	2 25	—	2 50
Toluidine-mixture	lb.	.75	—	.85

Black, reduced, 29 gravity, 25-30 cold test	gal.	21	—	22
Cylinder, light	gal.	36	—	38
Cylinder, dark	gal.	35	—	36
Paraffine, high viscosity	gal	40	—	41
Paraffine, 903 sp. gr	gal.	36	—	38
Paraffine, 865 sp. gr	gal.	26	—	28

Flotation Oils

(Prices at New York unless otherwise stated)

Pine oil, crude, f. o. b. Florida	gal.	44	—	
Pine oil, steam distillated, sp. gr. 0.925-0.940	gal.	53	—	
Pine oil, destructively distilled	gal.	49	—	53
Pine-tar oil, sp. gr., 1.025-1.035	gal.	35	—	
Pine-tar oil, double refined, sp. gr. 0.965-0.990	gal.	40	—	
Pine oil, light, sp. gr. 0.950, tank-cars, f. o. b. works	gal.	37	—	
Pine oil, heavy, sp. gr. 1.025, tank-cars, f. o. b. works	gal.	26	—	
Pine tar, thin, spo. gr. 1.060-1.080	gal.	30	—	
Turpentine, crude, spo. gr. 0.980-1.000	gal.	40	—	
Hardwood oil, f. o. b. Michigan, sp. gr. 0.960-0.990	gal.	19	—	
Hardwood oil, f. o. b. Michigan, sp. gr. 1.06-1.08	gal.	19	—	
Wood creosote, ref. f. o. b. Florida	gal.	31	—	

Vegetable and Other Oils

China wood oil	lb.	25½	—	
Cottonseed oil, crude	lb.	17	—	18
Linseed oil, raw, cars	gal.	1 54	—	1 55
Peanut oil, crude	gal.	1 37	—	
Rosin oil, first run	gal	41	—	
Rosin oil, fourth run	gal.	.58	—	
Soya bean oil, Manchuria	lb.	.19	—	.19½
Turpentine, spirits	gal	.41	—	

Miscellaneous Materials

Barytes, floated, white, foreign	ton	Nominal		
Barytes, floated, white, domestic	ton	30 00	—	36 00
Beeswax, white, pure	lb.	.56	—	.64
Casein	lb.	.22	—	.30
Chalk, light, precipitated, English	lb		—	
China clay, imported, lump	ton	17 50	—	36 00
China clay, domestic, lump	ton	12 50	—	20 00
Feldspar	ton	8 00	—	12 00
Fluorspar, gravel, f. o. b. mines	ton	33 00	—	35 00
Fuller's earth, powdered	100 lb	1 00	—	1 50
Graphite, flake	lb.	.16	—	.18
Ozokerite, crude, brown	lb.	.65	—	.75
Ozokerite, American, refined, white	lb.	.75	—	1 00
Red lead, dry, carloads	lb.	.10	—	.11½
Rosin, 280 lb	bbl.	6 15	—	
Soapstone	ton	10 00	—	12 50
Talc, American, white	ton	15 00	—	22 00
White lead, dry	lb.	.09	—	.10

Refractories, Etc.

(F. O. B. Works)

Chrome brick	net ton	Nominal		
Chrome cement, German	net ton	Nominal		
Clay brick, 1st quality fire clay	per 1000	50 00	—	55 00
Clay brick, second quality	per 1000	35 00	—	40 00
Magnesite, raw	ton	30 00	—	35 00
Magnesite, calcined	ton	32 00	—	35 00
Magnesite, Grecian, dead burned	net ton	85 00	—	90 00
Magnesia brick, German, 9x4½x2½	net ton	135 00	—	140 00
Silica brick	per 1000	50 00	—	60 00

Ferroalloys

Ferrocarbontitanium, 15-18 per cent., carload, f. o. b. Niagara Falls, N. Y.	ton	200 00		
Ferrocerium	oz.	20 00		
Ferrochromium, per lb. of Cr	lb.	50		
Ferromanganese, domestic, 70 per cent.	ton	250 00		
Ferromanganese, English	ton	325 00		
Ferromolybdenum, per lb. of Mo	lb.	2 00		
Ferrophosphorus, 75 per cent., f. o. b., N. Y.	ton			
Ferrosilicon, 50 per cent.	ton	180 00	—	190 00
Ferrosilicon, 50 per cent.	ton	165 00	—	175 00
Ferrotungsten, 75-85 per cent.	lb.	2 25	—	2 35
Ferrouranium, f. o. b.	lb.	7 00	—	7 50
Ferrovanadium, f. o. b.	lb.	4 00	—	5 00

Ores and Semi-finished Products

Antimony, 62 per cent.	lb.	1 60	—	1 70
Chrome ore, 42 per cent.	ton	1 40	—	1 60
Chrome ore, 48 per cent.	ton	1 90	—	
Manganese, 48 per cent.	lb.	1 2	—	
Manganese ore	ton	80 00	—	100 00
Molybdenite, per lb. of Mo	lb.	1 85	—	
Tungsten, Scheelite, per unit	unit	24 50	—	
Tungsten, Wolframite	unit	24 00	—	
Uranium oxide	lb.	3 25	—	3 60
Vanadium pentoxide	lb.	10 50	—	
Pyrites, foreign	unit	17	—	17½
Pyrites, domestic	unit	2	—	

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

The ALUMINUM ROLLING MILLS COMPANY, Cleveland, O. Capital, $1,000,000. To operate a local plant for the manufacture of steel, etc. Incorporators: F. H. Pelton and George B. Folk, Cleveland.

The ANNA LEE MINING COMPANY, Carthage, Mo. Capital, $75,000. To mine for lead and zinc. Incorporators: J. C. Wyatt, C. B. Pollard, R. A. Mooneyham, all of Carthage; C. Vernon, and W. C. Lucas, Kansas City.

The AUBUCHON SILICA MINING & MILLING COMPANY, St. Louis, Mo. Capital, $100,000. To mine for silica. Incorporators: Carl E. Aubuchon, Charles Spier, and Thomas B. Aubuchon.

The BOND CHEMICAL COMPANY, Camden, N. J. Capital, $125,000. To engage in the manufacture of chemicals and allied products. Incorporators: John J. Finney, Joseph Mallon, and F. M. Wick, Camden.

The CHICAGO COKE & CHEMICAL COMPANY, Portland, Me. Capital, $100,000. To operate a plant for the manufacture of chemicals, coke, iron, etc. Incorporators: P. B. Drew, C. G. Trott, and D. F. Drew, Portland.

The COLONIAL ANILINE WORKS, Monticello, N. Y. Capital, $10,000. To engage in the manufacture of dyestuffs and chemicals. Incorporators: P. S. Glickstein, W. and C. Lowenthal, 424 Caton Avenue, Brooklyn.

The CO-OPERATIVE FERTILIZER COMPANY, Miami, Fla. Capital, $30,000. To manufacture fertilizers. Incorporators: J. Petersen, C. M. Brown, Sr., and Charles D. Rowe.

The CORNWALL PAPER MANUFACTURING COMPANY, Cornwall, N. Y. Capital, $50,000. To manufacture paper and paper products. Incorporators: A. G. Lutz, F. B. Oldham, and L. Hecht, 403 Avenue C, Brooklyn, N. Y.

The DUNCAN LEAD & ZINC COMPANY, Duncan, Okla. Capital, $200,000. To engage in a general lead and zinc mining business. Incorporators: W. E. Williams, J. H. Goodnight, and W. M. Lockett, Duncan.

The EARLE CHEMICAL COMPANY, Wheeling, W. Va. Capital, $15,000. To engage in the manufacture of chemicals and kindred specialties. Incorporators: R. I. Runner, E. H. Draker, Eugene Hill, Raymond Sypher, and C. Rader, Wheeling.

The FOUNDRY EQUIPMENT & METALS COMPANY, Covington, Ky. Capital, $10,000. To operate a local foundry. Incorporators: L. A. and A. E. Clifton, and Frank X. Bertsch, Covington.

The HAMILTON ABRASIVE COMPANY, Westfield, Mass. Capital, $50,000. To manufacture abrasive materials of various kinds. Incorporators: F. D. Hamilton, Louis M. Fuller, and H. B. Putnam, Westfield.

The HARVEY CHEMICAL COMPANY, Hoboken, N. J. Capital, $50,000. To engage in the manufacture of chemicals and allied products. Incorporators: Jacob J. Harvey, East Orange; O. C. Harvey, Orange, and Harry B. Harvey, Newark.

The INTERSTATE LEAD & ZINC MINING COMPANY, Vinita, Okla. Capital, $40,000. To mine for lead and zinc. Incorporators: L. G. Sims, L. M. Linebaugh, Vinita, and S. P. Strong, Dallas, Tex.

J. F. LINBERG COMPANY, Inc., Jamestown, N. Y. Capital, $50,000. To manufacture chemicals and dyestuffs, etc. Incorporators: R. M. Bates, and E. J. and J. F. Linberg, all of Jamestown.

The LONE STAR LEAD & ZINC COMPANY, Miami, Okla. Capital, $200,000. To engage in a general lead and zinc mining business. Incorporators: B. C. Clark, Purcell; C. A. Clark, Oklahoma City; and R. I. Tibbs, Maypearl, Texas.

The LUDLUM STEEL COMPANY, Detroit, Mich. Nominal capital, $5,000. To manufacture steel and iron products. Incorporators: Lester P. Dodd, Norman J. Miller, and A. E. Perrin.

McCAFFREY & COMPANY, Inc., Philadelphia, Pa. Capital, $10,000. To engage in the manufacture of paper, paper boxes, etc. Joseph J. McCaffrey is the principal incorporator.

The MAXWELL PAINT COMPANY, Philadelphia, Pa. Capital, $10,000. To manufacture paints, etc. Morris Liveright is treasurer.

The MAYER & CLARKSON COMPANY, Buffalo, N. Y. Capital, $50,000. To manufacture iron and steel mill, shop, and foundry supplies. Incorporators: Alfred L. Mayer, A. A. Mayer, and C. B. Clarkson.

The MORRIS COUNTY CHEMICAL WORKS, Butler, N. J. Capital, $100,000. To operate a plant for the manufacture of chemicals, etc. Incorporators: John A. Marszalek, Thomas L. Sexsmith, William Joyce, and Walter A. Clark, Butler.

The NATIONAL BASIC FERTILIZER COMPANY, Birmingham, Ala. Capital, $137,000. To manufacture basic phosphate fertilizer. Incorporators: C. E. Elgin, Searles, Ala.; J. W. Lowman, Albany, and W. S. Oglesby, Searles, Ala.

The NEW LONDON CHEMICAL COMPANY, New London, Conn. Capital, $50,000. To manufacture chemicals and allied products. Incorporators: Bert W. Flanders, Ira M. Comstock, and H. E. Harris, New London.

The PANTO LEAD & ZINC COMPANY, Ada, Okla. Capital, $100,000. To mine for lead and zinc, etc. Incorporators: J. G. Witherspoon, Harmon Ebey, and Frank Jackson, Ada.

The PHILADELPHIA ELECTRIC STEEL CORPORATION, Wilmington, Del. Capital, $70,000. To manufacture electric steel and allied products. Incorporators: F. A. Armstrong, M. M. Clancy, and C. L. Rimlinger, Wilmington.

The PREMIUM ZINC MINING COMPANY, Oklahoma City, Okla. Capital, $75,000. To engage in the development of zinc properties. R. L. Ritchie is the principal incorporator.

The CHARLES H. PRIME COMPANY, Inc., New York. Capital, $50,000. To manufacture strawboard, boxboard, cardboard, etc. Incorporators: P. H. Smeallie, C. H. Prime, and J. K. Voorhees, 200 Fifth Avenue.

The PYROTOL CHEMICAL COMPANY, Beaumont, Tex. Capital $35,000. To manufacture chemicals and allied products. Incorporators: Bruce Richardson, S. Gordon, E. J. Goodier, and A. H. Safir.

The RED RIVER VALLEY LEAD & ZINC COMPANY, Durant, Okla. Capital, $50,000. To engage in the development of lead and zinc lands. Incorporators: George B. Morris, G. Thompson, Durant, and J. H. Holland, Achille.

The ROBAX CHEMICAL COMPANY, Dover, Del. Capital, $100,000. To manufacture chemicals and kindred specialties. Incorporators: Cornelius A. Cole, Hackensack, N. J.; Arthur R. Oakley, Pearl River, N. Y.; and Paul E. Britsch, Brooklyn, N. Y.

JACOB RUBIN & SON, New York. Capital, $75,000. To manufacture plate and window glass. Incorporators: J., H. H. and L. Rubin, 1516 Fifty-fourth Street, Brooklyn.

The RUBY JACK MINING COMPANY, Harrison, Ark. Capital, $200,000. To mine for lead and zinc. Incorporators: C. C. Wolf, O. L. Perry, D. M. Ormand, Harrison.

The SEABOARD BRASS FOUNDRIES, Inc., Brooklyn, N. Y. Capital, $52,500. To operate brass and other foundries. Incorporators: Donald Hayes, 5 Hanson Place, and C. Holter, 173 Lenox Road, Brooklyn.

The UNITED STATES PAPER MILLS, Inc., Chambersburg, Pa. Capital, $30,000. To operate mills for the manufacture of paper. Milton Long is the principal incorporator.

The VOLCO LEAD & ZINC COMPANY, Oklahoma City, Okla. Capital, $200,000. To engage in the development of lead and zinc properties. Incorporators: O. R. Jeter, Brinkman; N. U. Stout, Snyder, and S. M. Jones, Headrick, Okla.

The WESTERN CHEMICAL PRODUCTS COMPANY, Vernon, Cal. Capital, $25,000. To manufacture chemicals and allied products. Incorporators: G. W. Marchand, Long Beach; W. T. Moore, Long Beach, and T. C. Yeager, Canton, Mo.

Construction and Operation

Alabama

BIRMINGHAM.—Announcement has been made by the Tennessee Coal, Iron & Railroad Company that extensive improvements and additions will be made at its Fairfield byproduct coking plant which will double the present capacity. The work includes the construction of two additional batteries of seventy-seven ovens each, or a total of 154 ovens, together with complete byproduct recovery plants. The ovens will be of the Koppers type. It is said that the project will involve an expenditure of about $2,000,000. George G. Crawford is president.

LOCK TWELVE.—In addition to the expenditure of $30,000,000 planned by the Government for the construction of a nitrate plant at Muscle Shoals, it is understood that an expenditure of $500,000,000 is planned for the erection of additional nitrate plants, one of these to be located near Lock Twelve on Warrior River.

Arizona

TUCSON.—Alfred Roos, of Tucson, and associates, are planning for the immediate construction of a large new plant for the handling of wulfenite concentrates.

MIAMI.—The Miami Copper Company is considering plans for the construction of a new addition to its plant to increase the present capacity. A 6,000-ton mill is now in operation.

California

BISHOP.—The Round Valley Tungsten Company is planning for extensive development work at the camp at the Pine Creek tungsten claims recently acquired, including the installation of two new Marcy mills having a combined capacity of 150 tons daily.

BOLINAS.—The Chetco Mining Company has commenced extensive development at its copper properties in Marin County near Bolinas, and operations have been inaugurated in a new 40-ton mill, comprising crusher, Hendy ball-mill, and Overstrom concentrator.

CRESCENT MILLS.—The Juneday Mining & Milling Company has completed the installation of new machinery at its properties in Plumas County, and is planning for the construction of a new 50-ton mill.

PITTSBURG.—The Columbia Steel Company is making rapid progress in the construction of a new addition to its plant to increase the present capacity by about fifty per cent. Immediately upon completion of the structure, the company will commence the installation of two 30-ton and one 10-ton traveling cranes and a new 15-ton locomotive crane. Power for operation will be supplied by the Pacific Gas & Electric Company.

SAN FERNANDO.—Plans have been filed by the San Fernando Canning Company for the construction of a new canning works, about 100 x 475 feet. The structure, contract for which has been awarded, is estimated to cost $25,000, and the equipment to be installed will cost $40,000.

Colorado

CRIPPLE CREEK.—The Camp Bird Mining, Leasing & Power Company has had plans prepared for the construction of a large new ore-house at its properties.

NEDERLAND.—The La Plaisance Mining & Milling Company, recently incorporated, is planning for extensive development work at the La Plaisance gold and silver mine, to be operated in connection with the New England mine. E. V. Grant, F. A. Fair, and Alfred Dawson are interested in the company.

PUEBLO.—Negotiations have been completed by the Norcross Chemical Company for the leasing of the plant formerly occupied by the Table Queen Baking Company on South Union Avenue, and the company is planning to commence work on alterations and improvements to utilize the plant as a chemical manufacturing works and laboratory. New machinery will be installed immediately upon completion of these improvements, the new plant to be devoted to the manufacture of bismuth compounds, copper oxide, and iodoform. The company has completed the construction of a large new manufacturing plant near Stone City, which will manufacture various acids and explosives. W. E. Young is vice-president.

SILVERTON.—The D., L. & W. Mining and Reduction Company is engaged in extensive development work at its properties, and plans are under consideration for the construction of a new mill along the Animas River. H. M. Kingsley is manager.

Connectnicut

BRISTOL.—The plant of the Munroe & Muzzy Pen Company, located in the Edgewood district, near Bristol, was recently partially destroyed by fire, with loss estimated at $50,000.

STAMFORD.—Baer Brothers, Canal Street, manufacturers of paints, etc., have commenced the reconstruction of the portion of its plant recently destroyed by fire, with loss estimated at $100,000. The company is planning to increase the former capacity of the plant.

Idaho

MULLAN.—The Copper King Mining Company is considering plans for the construction of a new 200-ton mill at its plant. H. W. Ingalls is manager.

SAGLE.—The Armstead Mines Company, which operates on Pend Creille Lake, has made an appropriation of $200,000 to provide for the erection of a new 100-ton mill and other development work. Plans have been prepared by O. H. Hofstrand, Salt Lake City, Utah. H. H. Armstead is president.

Illinois

CHICAGO.—The Interstate Iron & Steel Company, Seventy-eighth Street and South Chicago Avenue, has had plans prepared for the construction of a new one-story addition to its plant.

EAST ST. LOUIS.—The Lubrite Refining Company, Tulsa, Okla., has had plans prepared for the construction of a large new local plant on property recently acquired near Twentieth Street and the Alton & Southern Railroad, comprising about twenty-five acres. The plant, which will be devoted to the production of airplane lubricants, will have an initial capacity of 1,000 barrels daily, ultimately to be increased to 5,000 barrels. W. S. Strickler is president.

LA SALLE.—The Valley Chemical Company is rushing to completion the construction of a large new addition to its plant. Immediately upon completion of the structure, which it is estimated will be within the next three months, the company will install the necessary furnaces and machinery for operation.

Indiana

EVANSVILLE.—Plans have been completed by the Hercules Gas Engine Company for the construction of a large new addition to its plant, the structure to be one-story, about 175 x 450 ton. It is estimated that the new building will cost about $150,000.

TERRE HAUTE.—Plans are under consideration by the Rott Glass Company for the construction of a new addition to its plant.

Iowa

BELMONT.—The Valley Sugar Company, recently organized, has acquired the Elder property comprising about 270 acres and is planning for the construction of a large new plant for the production of beet sugar.

CEDAR RAPIDS.—Plans are under consideration by the Viking Pump Company, manufacturer of pumping machinery and equipment for the construction of a new addition to its plant, about 35 x 125 feet. The structure is estimated to cost $20,000.

Kansas

WICHITA.—The Lucky Eight Oil & Gas Company is planning for the construction of a large new oil refinery on a site now under consideration at Eldorado to have an initial capacity of 2,000 barrels daily. It is expected that the new plant will be ready for operation by August 1. F. L. Wright is president.

Kentucky

LOUISVILLE.—The Louisville Fertilizer Company, operating a mixing plant for the production of commercial fertilizer, is said to be considering the construction of a large plant on property adjoining its present works, the new factory to be devoted to the manufacture of nitrates.

Louisiana

LAKE CHARLES.—The United States Government has awarded a contract for the construction of a large new local oil refinery and research building to the American Construction Company, Houston, Tex., and work will commence at once.

Maryland

CUMBERLAND.—F. Brooke Whiting and J. Blaine White are arranging for the organization of a new company to operate the plant formerly occupied by the Eastern Glass Works, at South Cumberland. The works comprise five acres and extensive alterations and improvements will be made. The plant will be devoted to the manufacture of high grade glassware and it is expected to be completed within three months, giving employment to about 100 hands for initial operations.

Michigan

ALMA.—The R. & P. Tractor Company, recently incorporated, is planning for the immediate establishment of a local plant. F. W. Ruggles is president.

IRON MOUNTAIN.—The Aragon Mining Company is planning for the immediate operation of the Oliver properties, Norway, near Iron Mountain. New mining machinery will be installed immediately the entire plant to be electrically operated.

WAYNE.—The Harroun Motors Corporation is considering plans for the construction of a new one-story addition to its plant. It is said that the structure, which is estimated to cost $150,000, will be used for the manufacture of shells for the Government.

Mississippi

CHARLESTON.—The Lamb-Fish Lumber Company has recently awarded a contract to the Unit Construction, St. Louis, Mo., for the construction of a large plant for the extraction of denatured alcohol and acetone from mill waste. It is said the works will cost about $1,000,000.

Missouri

ST. LOUIS.—Plans are under consideration by the Johnston Tin Foil & Metal Company, South Broadway, for the construction of a new two-story plant about 50 x 100 feet. The works are estimated to cost about $50,000.

ST. LOUIS.—The St. Louis Coke & Chemical Company is having plans prepared for the construction of its proposed new plant at Granite City, Ill., estimated to cost $5,000,000. Included in the plans is the erection of a byproduct coke oven and two blast furnaces. This company is a subsidiary of the American Coke & Chemical Company.

Montana

EAST HELENA.—The Economy Mining Company is making rapid progress in the construction of a new 75-ton concentrating mill at the Economy mine, and extensive additional development work is contemplated.

Nevada

ELKO.—The Standard Oil Shale Company, which was reorganized at Salt Lake City, Utah, with a capital of $1,250,000, is planning for the construction of a new 100-ton plant for the distillation of oil from shale at its Elko properties. The company has acquired 1000 acres of land near Elko, and 1000 acres near Levan, Juab County, Utah.

New Mexico

HANOVER.—The Republic Mining & Milling Company has plans under consideration for the construction of a new 100-ton concentrating mill.

New Jersey

JERSEY CITY.—The Hudson County Smelting & Refining Works has filed authorization papers to operate a smelting and refining plant at 489 Henderson Street. Jacob Laffer, 161 Pavonia Avenue, Jersey City, head, the company.

KEARNY.—Swift & Company have filed plans for the construction of a new five-story reinforced-concrete rendering plant to be located in the Kearny meadow district. It is said that this will be the largest plant of its kind in the East, the company planning to have a capacity of about 3,000,000 pounds of raw product monthly.

NEWARK.—The Butterworth-Judson Corporation, Avenue R, manufacturer of chemicals, is having plans prepared for the reconstruction of the portion of its plant recently destroyed by fire, with loss estimated at $200,000.

NEWARK.—The International Oxygen Company has taken out a building permit for the construction of a new plant at 796 Frelinghuysen avenue, estimated to cost about $20,000.

ELIZABETH.—The Linden Tanning Company has completed negotiations for the purchase of the tanneries of M. Straus & Sons, located at 42–68 Frelinghuysen Avenue, Newark, consisting of a series of two, three and four-story brick buildings containing approximately 250,000 square feet of floor space. The property was held at $300,000.

PERTH AMBOY.—The American Smelting & Refining Company has had plans prepared for the construction of a new addition to its plant to cost about $75,000.

PERTH AMBOY.—The Roessler & Hasslacher Chemical Company has taken out building permits for the construction of two new additions to its plant. Contracts for the structures have been awarded.

JAMESBURG.—The Texas Refining Company has recently acquired property near Jamesburg as a site for the construction of a new plant for the manufacture of lubricants. Construction work has been commenced on one of the units of the plant, a structure 50 x 50 feet. It is said that the company has received a contract from the Government for 10,000 barrels of grease for auto trucks.

BAYONNE.—The Standard Oil Company of Avenue K, having a frontage of 621 feet on the Kill von Kull, and extending about 800 feet to the National Docks Railroad, for a consideration said to be in the neighborhood of $775,000. It is said the property will be used for extensions.

New York

NEW YORK.—The American Aniline Products Company, 80 Fifth Avenue, has acquired the plant of the United Piece Dye Works, Nyack, N. Y., occupying the entire block fronting on Railroad Avenue, Cedar Hill Avenue, Hudson and Florence Streets. The works comprise a number of brick buildings having a total floor space of about 90,045 square feet, and the property was held at $105,000. The company is planning to use the plant for the manufacture of aniline colors, principally khaki and navy blue, having secured a large contract from the Government.

BROOKLYN.—The Long Island Soap Company has had plans prepared for the construction of a new three-story reinforced-concrete plant, about 50 x 80 feet, at Bridgewater Street and Meeker Avenue. David M. Ach, 1 Madison Avenue, New York, is architect.

FULTON.—The Oswego Pulp & Paper Company, Fulton, has had plans prepared for the construction of a new three-story local plant, to cost about $60,000. Charles Eaton, Watertown, is architect.

Ohio

CLEVELAND.—The Standard Foundry Manufacturing Company has taken out a brick and reinforced-concrete addition to its plant at 2717 East Seventy-fifth Street.

CLEVELAND.—Fire on April 10 following an explosion damaged the plant of the Grabler Manufacturing Company to the extent of approximately $200,000. The company was engaged in the manufacture of hand grenades for the Government.

COLUMBUS.—The Columbus Metal Company, recently incorporated with a capital of $30,000, has inaugurated operations in its new foundry at 459 South Parsons Avenue. The company will engage in the manufacture of castings of all kind.

HAMILTON.—The Beckett & Marquardt Company has taken out a building permit for the construction of a new reinforced-concrete factory building on Mill Road, to cost about $25,000.

YOUNGSTOWN.—The Carnegie Steel Company is preparing plans for the construction of extensive additions to its local plant, including the erection of a large new byproduct coke plant.

YOUNGSTOWN.—The Liberty Steel Company has plans under consideration for the construction of additions to its local plant to increase its present capacity. It is said that the company will make $600,000 of the additions, of which $350,000 will be contributed and $750,000 preferred to provide working capital for the period. At the present time the plant has a capacity of 600 tons of ingots per year, and it is proposed to increase this to 20,000 tons annually.

Oklahoma

POTEAU.—Edgar A. Berry and associates, operating a plant at Okmulgee for the manufacture of window glass, have completed negotiations with the local Chamber of Commerce for the removal of its plant to Poteau. It is estimated that the new works will cost about $50,000 and will give employment to about 125 hands for initial operations.

Pennsylvania

PHILADELPHIA — Fels & Company, Seventy-third and Woodland Avenue, manufacturers of soaps, have had plans prepared for the construction of a new one-story brick addition to their plant, about 65 x 95 feet, at Woodland Avenue and 73rd and Road. Harris & Richards, Drexel Building, Philadelphia, are the architects.

MARCUS HOOK.—The General Chemical Company, 25 Broad Street, New York, has recently awarded a contract for the construction of a new one-story and basement service building, about 100 x 100 feet, at Marcus Hook. The structure is estimated to cost $100,000. The Carleton Company, 151 West Forty-second Street, New York, is the contractor.

NEW CASTLE.—The Grasselli Powder Company, Cleveland, O., has commenced the construction of its new local acid manufacturing plant, which will comprise eight one-story units and a power plant for works operation. It is said that the plant, when completed, will represent an investment of about $1,000,000.

PITTSBURGH.—The Yankee Steel Company of America, recently incorporated under Delaware laws with a capital of $1,000,000, is considering the construction of a large plant near Sharpsville for the manufacture of sheet steel products. Ephraim Truxall is president and general manager.

Rhode Island

PROVIDENCE.—The Standard Oil Company of New York has acquired a large tract of land near its local distributing station, and is said to be planning for the construction of a large new refinery, can factory, and shipbuilding works.

Texas

HOUSTON.—The Prairie Oil & Gas Company has recently acquired property on the Houston Ship Channel, comprising about 400 acres, as a site for the construction of a large new oil refinery. It is said that plans are under consideration for the construction of a pipe line from Cushing, through Ranger, to the ship channel.

QUANAH.—T. Sanford Gibbs is having plans prepared for the construction of a new concentration mill at his copper properties near Quanah.

Utah

GOLD HILL.—The Deep Creek Investment Company is considering the construction of a new local mill for the treatment of low-grade ore. F. W. Ferriss is president.

MARYSVALE.—Rapid progress is being made by the Florence Mining Company in the construction of a new 100-ton mill at its alunite properties. Jacob Young is manager.

Washington

CHEWELAH.—The Northwest Magnesite Company is planning for the installation of new machinery at its plant to provide for increased capacity. The improvement is estimated to cost $150,000.

KELLER.—The Iron Creek Mining Company is planning for the early construction of a new 25-ton mill at its properties.

West Virginia

MORGANTOWN.—The Economy Tumbler Company is planning for the construction of new additions at its glassware manufacturing plant to cost about $175,000.

PARKERSBURG.—The Brown Flint Glass Company, recently incorporated with a capital of $50,000, has completed its organization and is planning for the manufacture of glassware. J. W. Brown, of Vienna, is president.

Wisconsin

CUBA CITY.—The Hercules Mining Company of Wisconsin, recently incorporated with a capital of $100,000, is planning for the construction of a new 100-ton mill at its local properties located near Plattesville. Harry Seemiller is general manager.

Canada

TORONTO, ONTARIO.—Fire recently destroyed a portion of the plant of the Thor Iron Works, foot of Bathurst Street, with total loss estimated at $300,000.

Mexico

CANANEA.—The Calumet-Sonora Mining Company, whose properties are located about four miles from Cananea, has completed the construction of a new 500-ton concentrating plant for the treatment of ore from the Catalina mine.

Trade Notes

The ZAREMBA COMPANY, of Buffalo, has moved its offices to the Niagara Life Insurance Building, corner of Franklin and Mohawk Streets.

The YARNALL-WARING COMPANY, of Philadelphia, has decided to group its several power-plant accessory products under the family name of "Yarway."

The HUFF ELECTROSTATIC SEPARATOR COMPANY, owners and manufacturers of the electrostatic process of ore concentration, have opened an office at 120 Broadway, New York, for consultation regarding ore dressing problems, especially the dry concentration of ores and the separation of valuable minerals from others which are commercially detrimental. The office will be in charge of A. L. Sweetser.

The EASTON CAR & CONSTRUCTION COMPANY, Easton, Pa., announce the opening of a new Branch Office in Washington, D. C., the address being 225 Kellogg Building, 1422 F. Street, N. W.

SWEDISH BEATER FILLING NOW MANUFACTURED IN THE UNITED STATES.—Helin's beater filling, which has met with much success in Europe and particularly in Sweden, is now being manufactured and marketed in the United States by the Fibre Making Processes, Inc., 440 So. Dearborn Street, Chicago, Ill. This filling is a cast iron composition, combining a structure of basalt lava with strength and durability. The manufacturers claim that compared with steel knives this filling doubles the capacity with about the same power consumption.

NATIONAL ANILINE DIRECTORS.—At the annual meeting of the shareholders of the National Aniline and Chemical Co., Inc., held at 244 Madison Avenue, New York City, on February 18th, 1918, the following board of directors was elected:

Dr. Wm. Beckers, New York City.
H. H. S. Handy, Syracuse.
Dr. L. C. Jones, Syracuse.
Clinton S. Lutkins, New York City.
Wm. J. Matheson, New York City.
Eugene Meyer, Jr., New York City.
W. N. McIlravy, New York City.
T. M. Rianhard, New York City.
J. F. Schoellkopf, Buffalo.
C. F. Hugo Schoellkopf, Buffalo.
J. F. Schoellkopf, President, Buffalo.
Robert Alfred Shaw, New York City.
L. Frank Stone, New York City.
Dr. R. C. Taggersell, Buffalo.
Orlando F. Weber, New York City.
Henry Wigglesworth, New York.

The new names appearing in the above are Dr. Taggersell, chief chemist of the manufacturing department at Buffalo; Dr. Jones, chief chemist of the Semet-Solvay Company; Mr. C. S. Lutkins, Secretary of the General Chemical Company; Mr. Orlando F. Weber, now associated with the War Industries Board at Washington.

The house of PHILLIPPE BERGER, Paris, France, announces that it will send one of its engineers to the United States to be here during April and May. He will have full buying authority for machinery and raw materials and will consider propositions for the establishing of industries in France. Communications should be sent to M. León Belge, Hotel Biltmore, New York.

MARDEN, ORTH & HASTINGS CORPORATION, 61 Broadway, New York, has acquired the control of the Buttercup Oil & Car Company, of Louisville, Kentucky. Buttercup Oil & Car Company is reported to be one of the largest producers of edible oils in the United States, and it is understood that they will continue the refining of peanut, cocoanut and cotton seed oils, and other edible oils will be added to their production list.

SCHUTTE & KOERTING CO., TRANSFERRED.—At a meeting held on February 23, 1918. The stock of the company was transferred to the alien property custodian of the United States and at his instance the Board of Directors was reconstructed as follows: E. Pusey Passmore, Governor of the Federal Reserve Bank, Philadelphia; Ralph J. Baker, Asst. Gen'l Counsel of the alien property custodian; D. W. Hildredth, treasurer of Schutte & Koerting Co.; T. H. Johnston, Schutte & Koerting Co.; Chas. S. Calwell, president Corn Exchange National Bank, Philadelphia. The new board elected the following officers: Chas. S. Calwell, president; D. W. Hildreth, treasurer; Ralph J. Baker, secretary.

This ensures the active continuation of the business in all its lines.

THE SURFACE COMBUSTION CO. has changed its address from Long Island City to 366-368 Gerard Ave, Bronx, N. Y., where increased space and new equipment has been provided.

The PERMUTIT CO., manufacturers of water softening and water rectification apparatus, and for several years past located at 30 E. 42nd Street, New York, announces its removal on March 15th to 440 Fourth Ave., New York.

MONSANTO AND COMMERCIAL ACID CO. CONSOLIDATE. — The Monsanto Chemical Company of St. Louis has purchased the Commercial Acid Company of East St. Louis for a consideration in excess of $2,000,000. Announcement to this effect was made recently by John F. Queeny, president of the Monsanto Company.

The Commercial Acid Company's plant is on a tract of 140 acres, and is one of East St. Louis' largest industrial institutions. The Monsanto Company is one of the leading manufacturers of medicinal chemicals in this country, its plant occupies two blocks in South St. Louis. The new corporation will be capitalized at about $5,000,000.

DYE PATENT LICENSES FOR DU PONT.—Recent applications to the Federal Trade Commission for licenses to manufacture under German-controlled patents under the "trading-with-the-enemy" act include several from E. I. du Pont de Nemours & Co. as follows: Applications covering patent No. 868,294, on a process of producing phenylglycin and its homologues, held by the Farbwerke Hoechst and patent No. 680,395, on a process of making indoxyl derivatives, held by the Roessler interests, of Frankfort-am-Main; No. 818,992, anthracene dye and process of making, patent of Bally & Isler; No. 787,859, anthracene compound and process of making, patent of Scholl & Bally; No. 1,003,268, anthracene dye and process of making, patent of Just & Wolf; No. 796,393, anthracene coloring matter and process of producing, patent of Bally; No. 753,659, anthracene derivative and process of making, patent of Rene Bohn; No. 739,145, anthracene dye, patent of Bohn; No. 1,055,701, pigment and process of making, patent of Bohn; No. 724,789, blue dye and process of making, patent of Bohn; No. 1,063,119 producing aminoanthraquinone and derivatives, patent of Rampini; No. 906,367, anthracene dye and process of making, patent of Bally & Wolff; No. 711,377, solid alkaline hydrosulphites and process of making, patent of Bazlen; No. 961,612, anthracene compound and process of making, patent of Isler & Wolff; No. 931,958, sulphur dye and process of making, patent of Haas; No. 795,755, process of making stable dry hydrosulphites, patent of Bazlen.

All of the last fourteen patents enumerated above were held on assignment by the Badische Anilin und Soda Fabrik, of Ludwigshafen am Rhein.

NEW CHEMICAL COMPANIES organized during January had capital of eleven million dollars compored with seven million dollars for such organizations in December and less than four million dollars for those formed in January a year ago. Capital invested in chemical companies for manufacture of chemicals, drugs and dyes in this country since the war began now stands at three hundred and thirty-nine million dollars.

Manufacturers' Catalogs

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, East Pittsburgh, Pa., has issued catalog 8-E, describing Westinghouse industrial heating apparatus.

THE CUTLER-HAMMER MANUFACTURING COMPANY, Milwaukee, Wis., has issued two small circulars, one on the "C-H electric space heater unit" and the other on the "C-H electric air heaters." An 8-page booklet has also been issued describing the Thomas meter for measuring gases and air in large quantities.

CENTRAL SCIENTIFIC COMPANY, Chicago, Ill., has issued circulars describing De Khotinsky constant temperature heating appliances and Cenco direct current meters.

SARCO COMPANY, INC., New York, has issued a folder describing Sarco metallic gasket.

ELECTRIC MACHINERY COMPANY, Minneapolis, Minn., has issued Bulletin 176 describing vertical type alternators directly connected to waterwheels.

Keep Our Young Men in College

OUR country is confronted with a serious menace to her future welfare through the patriotic response of her young college men to the call for military service. When the war began in 1914 there was a large volunteer movement among students from France and England, to such an extent, indeed, that England later found it necessary to recall from France her technically trained young men. France shortly discovered that her own schools were being deserted, and saw the necessity of recruiting students to furnish a supply of engineers and technologists for the future. With this experience before us, our educators were prepared to sound the necessary warning when the United States entered the war, and almost from the beginning of our participation we have made special efforts to keep young men in college, particularly those who were studying scientific and engineering courses.

More recent data on the situation have been made public through an article by Huber William Hurt in a recent issue of *School and Society*, wherein it is shown that thirty educational institutions in the United States have 26,000 fewer students than they had last school year. The total loss for the higher institutions of learning is estimated at 68,500, which is the number of vacancies that ought to be filled if our colleges and universities are to render full service to the country.

We conceive it to be the duty of engineers everywhere to take definite steps to see that young men now in college are shown the necessity of pursuing their work to the end, and that young men eligible for college training are urged and even assisted to attend a nearby college. There are dozens of ways for a young man to get through college if the spirit wills, and assistance may range from showing how the trick may be turned, to actual financial support during the period of instruction. Here is an opportunity for real service which engineers should not neglect.

Something Usually Lacking in Annual Reports

IT IS said that when the late Abram S. Hewitt was invited to join the board of the United States Steel Corporation at the time it was organized, he refused to do so unless the directors agreed to take the public into their confidence and tell in cold print everything that was done. He insisted that details be given which theretofore were held impossible to disclose, lest competitors learn too much. The argument lasted until late at night, the old ex-mayor holding that the concern was big enough to stand it; that the temper of the times demanded that all the facts be told; that whatever the corporation did that was right it could be proud of and

that whatever it did that was wrong would be found out anyway. He carried his point and to this day men of good-will have not regretted it. The Steel Corporation was one of the pioneers in telling stockholders and the public the things they should know but did not expect to learn. Things both favorable and unfavorable are told with splendid frankness.

The peculiarity—and we might almost say the trouble—with doing one good thing is that it is expected to lead to another, and then to another, and so on without ceasing. It is a feature of the *mores*, of the folkways, of public opinion, that if we blaze a trail of merit of any sort we are expected not only to continue in the path of righteousness, but to take the lead in other respects—all for the public good. One of the first things we learn in childhood is that obedience to parental discipline does not grant exemptions, even though other children persevere in naughtiness.

Now that publicity in the administration of affairs, and about bulk and tonnages, and things not done and things done, and building operations, and costs as well as profits, has been made in their annual reports, we conform to custom and cry for more. We want to see publicity in regard to the administration of materials and to learn about the progress of research from year to year. We are aware that the subject is delicate, that it would be indiscreet to reveal the things hoped for or that are of promise in laboratories or that have reached a semi-commercial scale. It would not be expedient to tell of strategems in manufacture for competitors to imitate. Dividends are, after all, the basis of industry and they must not be neglected. But this is just what we are coming around to: One of the most important features desired of dividends is that they bid fair to continue, and the best way to provide for future dividends is to keep ahead of the game, while the way to keep ahead of the game is by research.

Dr. Mees said the other night at a meeting of the Society of Chemical Industry at the Chemists' Club, that he had found both in England and America about the same cost for building and maintaining research laboratories before the war. He said that $3500 per man to be employed was approximately the cost to build and equip an industrial research laboratory designed for one establishment in one industry, and that the annual maintenance expenses were about the same. Thus if a corporation that had such a laboratory established were to state in its annual report that $35,000 had been expended from its research fund, it would have been fair guessing up to 1915 that there had been about the value of ten men engaged in this kind of work. Of course, it would only be guessing, and it would give no intimation of the merits or the results of the effort. We offer it merely as an alleged measuring stick with no guarantees whatever, beyond the intimation that Dr. Mees has done excellent work in the Eastman laboratory at Rochester, and that he speaks with large experience.

We have no desire to demand of corporations details of their business which it would be unwise to publish. We merely point out that all information on the subject of research is usually suppressed, which we think a mistake. We know, for instance, that the Steel Corporation is diligent in this respect, which reassures us as stockholders; but we learn nothing of it in their annual report.

It is surprising how rapidly the public mind changes. A few years ago the mere mention of a chemical expression was regarded as impolite because nobody reasonable was supposed to know what it meant—and chemistry was held to be made in Germany anyway! Now the question is constantly asked whether we are scientific enough to compete with European countries after the war. The anxiety is less serious in regard to the steel and certain non-ferrous metal industries than it is concerning those which are regarded as more specifically chemical; but it is well to remember that even in variety of special steels the Germans were eminent before the war.

Slowly the fact is dawning upon the public consciousness that in nearly every great industry somebody is working away all the time to find improvement or economy or variety, either in this country or somewhere else. Wherever sound research is carried on the chances are much greater that improvements will be discovered and developed. In one sense, research is going hunting; in another it may be regarded as a modified form of insurance towards future benefit, and it is fair to say that manufacturing organizations that do not engage in it, lack this insurance. They not only lack this insurance but they lack something else; for wherever research is carried on intelligently and with understanding and with a wholesome belief in it, the entire organization becomes alive with the consciousness that improvements are sought. It sharpens the eyes of the whole force and it drives away the monotony of work. Therefore we think it a good thing to tell something in annual reports of the attitude of the administration of great industrial establishments toward this subject; to give at least the encouraging information, if the facts bear it out, that research is in progress.

Of course the rule-of-thumb people are always anxious to prove that they are scientific, science having come into fashion of late. If anything is said of research by the real leaders who engage in it, the rule-of-thumb people will follow the lead and, as likely as not, issue what is sometimes called "blurbs" on their control laboratories in the hope that a credulous public will believe them to be maintaining institutes of research. This will not mislead the technical press. The very ignorance of technical matters within boards of directors about which we have frequently complained is likely to show itself in this respect. But if those who engage in genuine research can be induced to tell something of the measure of their activities in this great field, it may give the less progressive concerns enough of a jolt to make them see a light—which would be a great benefit to American industry.

Iron and Steel Production Rates

IN January and February pig iron was produced in the United States at an average rate below 30,000,000 tons a year. Since April 1 the rate has averaged well above 40,000,000 tons. A favorite estimate of blast-furnace capacity now existing is 43,000,000 tons, and it is quite possible that pig iron will be produced at such a rate in the near future. The controlling factor has been coke. Estimates of the steel ingot capacity range from 47,000,000 to 50,000,000 tons, but from the pres-

ent alignment it seems improbable that if pig iron production reaches a rate of 43,000,000 tons ingot production will reach a rate of 47,000,000 tons.

These and related facts embody two problems: (1) There was something radically wrong with coke production, movement and utilization last winter, and a recurrence of the conditions next winter must be avoided. (2) There is room for further ingenuity on the part of steel works managers in making bricks without straw, or in other words open-hearth steel with a scrap supply quite below normal.

It may prove to have been a very costly oversight if the experience of last winter's curtailment in pig iron production is remembered merely as a shortage of transportation for coke. That has been the common view, but there was a great deal more in the matter than that. The amount of pig iron that was produced, in January and February, from the coke that was available, was far below what would have been produced from that amount of coke under normal working conditions, and as conditions have been partly righted there has been a greater increase in the production of pig iron than in the production of coke.

There were three factors producing an inefficient utilization of the facilities that were available. In the first place, the beehive ovens in many cases did not produce good coke because, awaiting cars, coke was frequently held in the oven too long. In the case of the Connellsville region at least the coke operator was not free to blow out ovens, when car supplies averaged less than necessary to take care of full production by the ovens in blast, because he did not wish to commit business suicide. The absurd system of car distribution in the Connellsville region allots cars, when there is an insufficient supply on the railroad division, in proportion to the number of ovens in blast at each plant. If the operator blows out some ovens this week, his allotment is cut down next week. It is not instantaneous suicide, but the process would be sure. The result of the absurd system of the railroads is poor coke, overburned, and high coke consumption per ton of pig iron produced. In the second place, through irregularities in the receipt of coke, many blast furnaces had to bank at intervals. At such times the coke consumption per ton of pig iron produced is the invariable result when a finite quantity is divided by zero, the symbol being ∞. In the third place, many blast furnaces had to run at gaited rates for long periods. The detached furnace, or pair of furnaces, had no alternative but to make the best of things. A valley furnace manager made what was considered a remarkable record, running at about 50 per cent for several weeks, with an increase of only 10 per cent in coke consumption, but that would be an 11 per cent loss in pig iron over what would have been produced in the industry as a whole if the furnaces operated thus, instead of enough being blown out to give a full coke supply to the remainder.

A compilation showing the coke consumption per ton of pig iron at all blast furnaces last January and February, compared with normal performance at the same furnaces is needed, not to prove that there was much waste of coke last winter, plus much production of poor coke, for the general facts are known, but to emphasize how serious the loss was. If anyone has doubt that there was a very serious loss, let him reflect that conditions as to quality of coke and quantity and regularity of supply were much less objectionable in the year 1917 as a whole than they were last winter. Then let him seek an explanation of the statistical fact that from 1916 to 1917 there was an increase of 2,000,000 tons in the production of coke (Geological Survey) and a decrease of 800,000 tons in the production of pig iron (American Iron and Steel Institute).

No such experience must occur next winter. It is to be hoped that there will be ample transportation facilities, but if there are not, the cars available must be furnished in such manner as to conduce to as regular operation of beehive ovens as possible, and the production of the best coke that can be made. If there is not going to be enough coke at blast furnaces, then the coke must be so employed as to produce the maximum tonnage of pig iron possible with it.

The other problem, referring to the present and not next winter, is to bring about a better balance between pig iron production and steel ingot prodction. In proportion to rated capacities the production of steel ingots has been less than the production of pig iron, and that is a remarkable condition seeing that the iron foundries are not consuming their normal proportion of the total make of pig iron. The condition is due to one or both of two things—too much steel making capacity in proportion to blast furnace capacity, or not enough scrap. As long as pig iron does not accumulate, the individual works manager may be doing his best. He may have a full supply of pig iron, use it all, and get from his open-hearth furnaces only 85 per cent of their rated capacity. With more scrap he might produce ingots at 100 per cent.

The problem of regulating or controlling the scrap movement has been a very difficult one, in comparison with which the setting of prices on plates, or pig iron or even coke, has been extremely simple. It was necessary that scrap prices be limited, but when that was done very little scrap proved available. The dealers insisted that they should be permitted to charge a commission to consumers for handling scrap for them. After much discussion the commission was allowed, April 30, by the War Industries Board. Since then the offerings of scrap have not materially improved. The dealers have not made good on their representations that allowance of the commission would produce scrap, and the showing is particularly in point, because during the pendency of the discussion as to whether or not a commission would be allowed, holders of scrap would naturally keep it, while on the allowance of the commission they would hasten to sell. If there is scrap in the country the scrap should be found, commandeered by the authorities and put at the disposal of open-hearth furnaces.

If on the other hand there is not going to be a normal supply of scrap, the balance fitting the situation should be produced. If there is not enough blast-furnace capacity in proportion to steel-making capacity, the necessary steps should be taken, under authority of the Government, to hasten completion of blast furnaces now in course of erection, or to build new furnaces. There have been some remarkable records of blast-furnace building, when the builders had merely brains and money. Now the work could be hastened by government authority.

Southern Convention of the American Electrochemical Society

Tour of Southern Industrial Centers, Including the New Nitrate Plants at Muscle Shoals and New Power Developments in Tennessee and Alabama—Report of Technical and Business Sessions—F. J. Tone of Niagara Falls Elected President

THAT a war-time convention of scientists and engineers can be held with resultant benefit to the participants, the region visited and the nation at large was amply demonstrated by the American Electrochemical Society in its tour of the Appalachian South during the entire week of April 28. The serious purpose behind the convention and the prospective benefit to the country may be inferred from the action of Director General McAdoo in approving the use of a special train to transport the Society from Washington as far south as Birmingham and return.

AMERICAN ELECTROCHEMICAL SOCIETY

North and South were brought together in a way that could not have been accomplished otherwise, and those who had been strangers to the potentialities of the South realized the possibility of so developing the raw material and power resources of the region as to establish an extensive chemical and electrochemical industry in the course of the next few years. Certainly a good beginning has been made in the production of iron, steel, ferro alloys, fixed nitrogen, cement, wood pulp, coke and its by-products, sulphuric acid, dyes and explosives.

The establishment of two great nitrogen-fixation plants at Sheffield and Muscle Shoals, makes of northern Alabama one of our largest chemical and electrochemical centers. No one could visit these plants without experiencing a sense of pride in what has been accomplished up to date, and a feeling of gratitude toward those who have sacrificed personal interests for the nation's good by devoting their time, talents and professional experience to the vital matter of producing ammonium nitrate.

If the visitors from the North gained inspiration and knowledge from their trip, there is also abundant testimony from the Society's hosts that the meetings brought encouragement and professional gain to them. Notes were freely exchanged and the best of professional fellowship prevailed. That there was tangible gain to both host and guest was therefore inevitable. The nation's war program was uppermost in the minds of all, with the purpose to contribute in every possible way to its advancement.

Assembly and Registration at Washington

As a pleasant prelude to the railway journey, the members and guests of the Society who had gathered at Washington on Sunday, April 28, were shown the courtesy of a private visit to the Executive Offices, Cabinet Room, etc., in the White House, through arrangements made with Secretary Tumulty by the Washington representative of METALLURGICAL & CHEMICAL ENGINEERING. The interest of the visitors centered not

only in the older historical events that had transpired in these rooms, but also in the vital national issues that are there decided from day to day at the present time. The war maps on the walls of the Cabinet Room, corrected daily to show the positions of the contending forces in Europe, were objects of special interest.

Directors Meet En Route

Leaving Washington Sunday evening, the directors of the Society assembled in the observation car for a meeting at which were presented the annual reports of officers and committees. The Society was found to be in excellent condition financially, and a comprehensive campaign for membership was outlined.

On the following day, Monday, April 29, two points in Tennessee were visited, Johnson City and Kingsport.

Johnson City, Tennessee

At this point known as the Gateway to the Appalachian South, the visitors were the breakfast guests of the local Chamber of Commerce. After an address of welcome by Lee F. Miller, president of Chamber, and response for the Society by President Fink, the visitors were taken about the city in automobiles. Time did not permit a visit to the chemical plant of the Clinchfield Products Co., manufacturers of barium products. It was also learned that this concern makes sodium sulphide for the production of dyes at the Federal Dye Stuff & Chemical Corporation at Kingsport, using as one of the raw materials nitre cake from the sulphuric acid works of the Tennessee Copper Co. at Copperhill.

Kingsport, Tennessee

This community is one of the most interesting and promising chemical centers of the South. It has been developed largely through the intelligent efforts of the Industrial Department of the Carolina, Clinchfield & Ohio Ry., and is an excellent example of logical and systematic planning to produce an independent and coordinated industrial center. The variety of chemical and other industries operating here is indicated by a partial list of the products: Cement, wood pulp, tanning extract, clay products, dyes, explosives, leather, wood distillation products and potash from cement. Add to these such local mineral resources as barytes, bauxite, feldspar, manganese, limestone, marble, mica, salt, phosphate and pyrite, and one readily sees a wonderful opportunity for future development.

Arriving at Kingsport the Society assembled at the Inn where addresses were made by V. V. Kelsey, J. F. Johnson and Ex-Governor John I. Cox, who reviewed the early history of the region and explained its resources. At noon the party was taken to Rotherwood Farm where a complimentary luncheon was served. In the afternoon the members were given an opportunity to visit the plants of the following companies: Federal Dye Stuff & Chemical Co., Clinchfield Portland Cement Corp., Kingsport Brick Corp., Kingsport Extract Corp., American Wood Reduction Corp., Kingsport Pulp Corp., and Kingsport Tanning Corp. Particular interest centered in the chlorine, dye and explosives departments of the Federal Co., the continuous causticizing plant[1] of the Pulp Corp., and the Cottrell potash-recovery plant at the Cement Corp., the last being under construction.

HOTEL TUTWILER, BIRMINGHAM, ALA.

Annual Business Meeting

In the evening a complimentary dinner was served at the Inn, followed by the annual business meeting and a dance at the Federal Club.

The annual report of the Directors showed among other items the investment of $2000 of the Society's funds in each of the three Liberty Loans. An amendment to the constitution providing for honorary members was adopted by a large majority. Officers elected

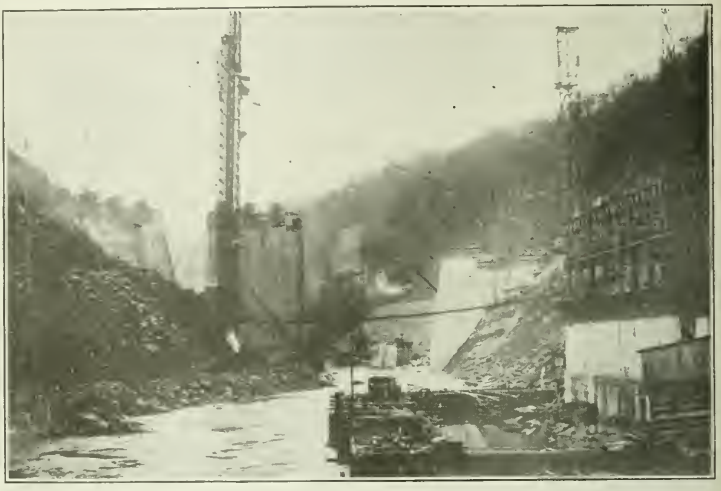
[1] See this Journal April 1, 1918, p. 376.

for the ensuing year were announced as follows: President, F. J. Tone; Vice-presidents, Acheson Smith, H. W. Gillett and R. Turnbull; Managers, C. F. Burgess, E. L. Crosby and C. G. Schluederberg; Treasurer, P. G. Salom; Secretary, J. W. Richards.

Knoxville District, Tennessee

Tuesday morning, April 30, the party had breakfast at Mascot as guests of the American Zinc Co., and later visited the company's zinc-ore concentration plant. An interesting feature of the flotation process at this plant is the preliminary treatment of the pulp with a solution of copper sulphate to aid in the flotation of the blende. The company's metallurgists have been conducting some interesting researches in preferential flotation, the results of which we expect to present in detail in the near future.

Arriving at Knoxville the party was taken immediately by special train as guests of the Board of Commerce and the Aluminum Company of America to see the hydro-electric developments of the latter on the Little Tennessee River. The complete project of this company contemplates the construction of a series of perhaps seven dams and power plants beginning at Alcoa and continuing at intervals up the river, each dam being located at the upper end of the lake created by the one next below. Work is now under way on No. 2 dam at Cheoah, as shown in the accompanying photographs. This dam is 200 ft. high and is reported to be the highest overfall dam in the world. During flood seasons water will flow 10 ft. deep over the crest. The power plant will develop 80,000 hp. The entire project is made possible through an agreement between the Aluminum Company and the Southern Railway providing for the relocation and construction of the latter's railroad.



DAM AND POWER HOUSE FOR ALUMINUM COMPANY OF AMERICA, AT CHEOAH ON THE LITTLE TENNESSEE RIVER

At noon the members of the party were guests of the Aluminum Co. at luncheon at Alcoa, the site of development No. 1.

Technical Session at University of Tennessee

Returning to Knoxville the Society assembled at the University of Tennessee where a technical session was held following a brief address by President Brown Ayres.

Hydro-Electric Power in Quebec and Ontario

A description of possible hydro-electric power development of the waters of the Ottawa River, near the city of Ottawa, and of the waters of the St. Lawrence River, near Montreal, was given by Louis Simpson, industrial engineer of Ottawa. He mentioned especially the Chats Falls, 32 miles west of Ottawa, where it is possible to develop between 110,000 and 120,000 e. hp. The possible head is 50 ft., and ice troubles can be reduced to a minimum. He also mentioned the possibility of constructing a canal from Lake St. Francis to a power house located on the Lake St. Louis, both these lakes being enlargements of the River St. Lawrence. The possible head will be 80 feet, and it will be possible to develop 1,000,000 hp. This development, also, if properly engineered, would be free from ice troubles.

In discussion of this subject Mr. C. A. Winder thought the author was too optimistic regarding freedom from ice troubles as featured in the paper, and also questioned the possibility of developing the amount of power on the Ottawa river as claimed by the author.

Mr. H. S. Randall, Jr., challenged the author's statement that there are but few undeveloped water powers of considerable magnitude, and cited Maine and Labrador as localities where large undeveloped powers still existed. In the latter country there are heads of over 200 ft. where there would be freedom from ice troubles.

Storage Battery Capacities

C. W. Hazeleit, storage battery engineer of the National Carbon Co., presented an interesting discussion of the calculation of storage batteries together with an alignment chart and circular slide rule for calculating these capacities. The use of one million storage batteries for automobile starting purposes imposes new conditions of service which former methods of determining capacities do not cover satisfactorily. It is important that final voltages be standardized as a continuous function of the time rate of discharge, in order that the condition of the cells at end of discharge at any time rate shall be approximately the same, and that all capacity data may be correlative. An equation for this final voltage is suggested and the work of Messrs. Spencer and Naiden was reviewed. They demonstrated that the capacity of the starting battery was a single, definite function of the time.

The conclusions from his work given by the author are as follows:

1. The systematization of storage battery testing demands that all data shall be based on time rates if they are in any way to be universal.

2. The capacity of any Faure or pasted-type starting battery cell between the time limits of 5 minutes and the 100-hour rates of discharge, and of all commercial-type vehicle plates between the 30-minute and 12-hour rates, is a definite single function of the time; *i. e.*, Log I f (T) (Log T) $= K$, where I is the current, T the time, K the capacity in ampere hours times some constant, and (f) (T) a definite function of the time.

3. It is essential to have a universal final voltage equation which is scientific and a definite function of the time. The formula

$$E = 1.85 - \frac{0.448}{\text{Log } T} (T \text{ given minutes})$$

is offered as a scientific and practical equation.

4. The charging and finish-charging rates of any cell should be a definite time rate of discharge. The 7- and 18-hour rates are respectively recommended.

Sign of the Live Electrode

A comprehensive discussion of this subject was given by Prof. W. D. BANCROFT, of Cornell University. Professor Bancroft said the German physical chemists have changed their position several times as to the sign to be applied to the zinc electrode. At present the Germans use the minus sign for the potential of zinc in zinc sulphate solution, as do also the English. In this country the practice is by no means uniform. Professor Bancroft summarized his discussion of the subject as follows:

1. The chemical potential of the zinc in the Daniell cell is greater than the chemical potential of the copper, but the electrical potential is less.

2. With electrodes which form cations the electromotive force is a measure of the difference of the chemical potentials, but has the opposite sign; with electrodes which form anions it has the same sign.

3. Since the electrical potential of the copper in the Daniell cell is higher than that of zinc, and since the zinc electrode is the place of lowest electrical potential, though highest chemical potential, we ought to use the minus sign when speaking of the electrical potential difference Zn | $ZnSO_4$.

4. Calling the zinc potential minus is in line with the practice of all physicists, of the Bunsen Society, and of the Faraday Society.

5. The distinction between chemical potential and electrical potential was stated concisely by Gibbs.

Discussing DR. BANCROFT'S paper, DR. HERING stated that it represented the views of the majority of a committee previously appointed to consider the matter. MESSRS. MOTT, HERING and BANCROFT favored the view just presented, while MR. WATTS thought that the use of the + sign for Na, Zn, etc., and the — sign for Cu, Pt. etc., would follow long established custom and avoid confusion. Dr. Hering stated that the difficulty was that those who originally guessed at the direction of the flow of the current had guessed wrong, with consequent misleading practice in the use of signs. DR. RICHARDS sympathized with the view of Mr. Watts on account of the phrasing of the author's conclusions, objecting to the statement that the electrical potential of Zn is less than that of Cu unless it is specified that it is algebraically and not numerically less.

Resistivity of Porcelain and Magnesia

Tests of the electrical resistivity of calcined magnesite and porcelain were described by P. H. BRACE, research chemist of the Westinghouse Electric & Mfg. Co. The resistivity was measured from 430 to 990 deg. C. of (1) calcined magnesite (impure magnesia) completely fused in an arc furnace and free from cracks and blow holes, (2) molded calcined magnesite baked at 1700 deg. C., (3) porcelain such as is used for spark plug insulators, using direct current. The magnesia had greater resistivity than the porcelain at all temperatures investigated. Uni-lateral effects due to the direct current were noted, and the porcelain gave back electromotive forces up to 0.7 volt.

DR. E. C. SULLIVAN thought the author had neglected to emphasize an important point, viz., that the change in resistance with time was less at high temperatures than at low. President FINK commented on the author's failure to tell how he fired MgO pellets at 1700 deg., and wondered what atmosphere was used. A reducing atmosphere would convert FeO to Fe which would coat the MgO and destroy the resistivity. This would account in part for the better resistivity of molded than fused MgO. DR. NORTHROP thought that results of greater scientific value would be secured if work of this type were done on pure substances of simple composition rather than on complex materials. The results obtained on the latter are empirical and useful only for some practical end, whereas the other procedure would enable us to determine the reasons for the results obtained.

Determination of Gases in Metals

A precision method for the determination of gases in metals was described by H. M. RYDER, research chemist for the Westinghouse Electric & Mfg. Co.

The metal to be investigated is mounted as a thin ribbon or filament in an electric-light bulb, which is then evacuated. The temperature of the filament is then raised by an electric current, and the pump being kept going the gases evolved are continually forced out into a collecting tube. The temperature is raised in steps of 50 deg. C. up to the melting point, and the gases evolved at each temperature measured and analyzed. The bulb is water-cooled, in order to prevent the glass giving off gases on becoming heated. One or two cubic millimeters of gas can be thus measured and analyzed. Silicon steel was found to give off gas abundantly at the Ar_1 point, 730 deg. C. The process of gas analysis is novel and interesting. The CO_2 and H_2O vapor are first frozen out with liquid air, and the remaining "dry" gases are pumped into a small chamber by means of a modified Töpler pump. The CO_2 is then separated from the water vapor by substituting carbon dioxide snow for the liquid air. The quantity of CO_2 released is determined by measuring with a McLeod gauge the pressure due to it in a volume accurately known. It is then pumped out of the system and the water vapor released by removing the carbon dioxide snow. The pressure due

to this is determined by using a mercury U-tube manometer with an optical lever attachment[1].

Oxygen is added to the remaining gases, which have been returned to the main analysis system, and the CO, H_2, and CH_4 burned in a small combustion bulb, a hot platinum filament being used to start the reaction. The CO_2 and H_2O vapor formed are measured as before and the quantity of CO, H_2, and CH_4 determined from this and a knowledge of the decrease in the quantity of the mixture of gases. CO added to the remaining gases and burned provides for the determination of the excess oxygen and any oxygen which might be originally present in the gases. Nitrogen is determined, technically, by difference, but the method permits of a check on its value.

Arc Furnace for Nitrogen-Fixation

A paper on this general subject, not on the program, was presented by E. Kilbourn Scott. He explained briefly the essential differences between nitrogen furnaces and others, to wit: the electrodes are of metal instead of carbon, and the voltage is 5000 or more. One difficulty with all single-phase furnaces is that a great deal of the air entering the furnace does not get into the arc and is unaffected. The author sketched a design of his own furnace, three-phase, in which a maximum of air is reacted upon by the arcs. He described the development of nitrogen furnaces from those of 150 kw. 10 years ago to 4000 kw. now. Yields of nitric acid have now been obtained as high as 85 grams per kw.-hr. at a concentration of 1.3 to 1.5 per cent.

Program at Banquet

On Wednesday evening the Cherokee Country Club was the scene of a banquet tendered the Society by the Knoxville Board of Commerce. Toastmaster Hugh M. Tate gave the proceedings a distinct patriotic tone and commented on the cosmopolitan character of the Society's membership as represented on the Southern tour.

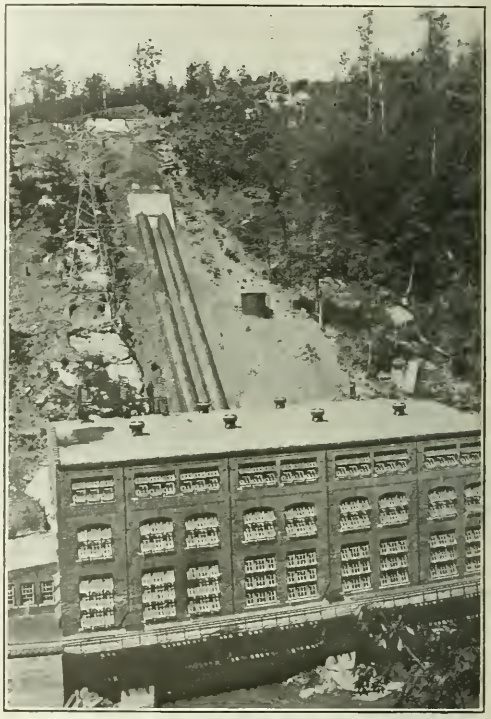
Three notable addresses were delivered following the banquet. The first was the annual address of President C. G. Fink, "Electrochemistry and National Economy." This will be published in full in a later issue.

The second was by John A. Switzer, professor of hydraulic engineering, University of Tennessee, who had during the preceding six weeks made a reconnaissance of undeveloped hydroelectric power sites in eastern Tennessee, capable of developing over 5000 hp. each. His surveys covered the Power, Clinch, Holston, French Broad, Hiwassee, Ocoee and Little Tennessee rivers. Stereopticon views were shown of the localities as well as of proposed dams and reservoirs. In all he described 21 sites at which could be developed a total of 750,000 hp. Prof. Switzer repeatedly explained in connection with several of the projects that the hydroelectric developments would be limited by the present location of railroad lines. Blue-prints were distributed showing the location of the 21 sites.

This third address was given by C. C. Schlueder-berg who spoke on "The Part United States Industries Must Perform to Enable the Allies to Win the War." The speaker showed the importance of our industries and the tremendous demands being made on them in the preparation of war materials. On the subject of abrasives and alloy steels he showed the vital relation existing between electrochemistry and the machine shop.

"It is an established fact that were it not for artificial abrasives, which, by the way, are prepared entirely in the electric furnace, the present output of automobiles, trucks, airplanes, and all other products of the machine shop would not be possible. It is readily conceivable that our success in this war will be at least in a measure due to our ability to produce abrasives artificially by electrothermal means.

"Coupled with the use of high-speed cutting tools made from alloy steel derived largely from the electric furnace, and the use of similar steel for machine parts where great strength is required, we have a good example of how modern scientific achievements have gradually worked their way into our every-day lives without our being aware of the fact."

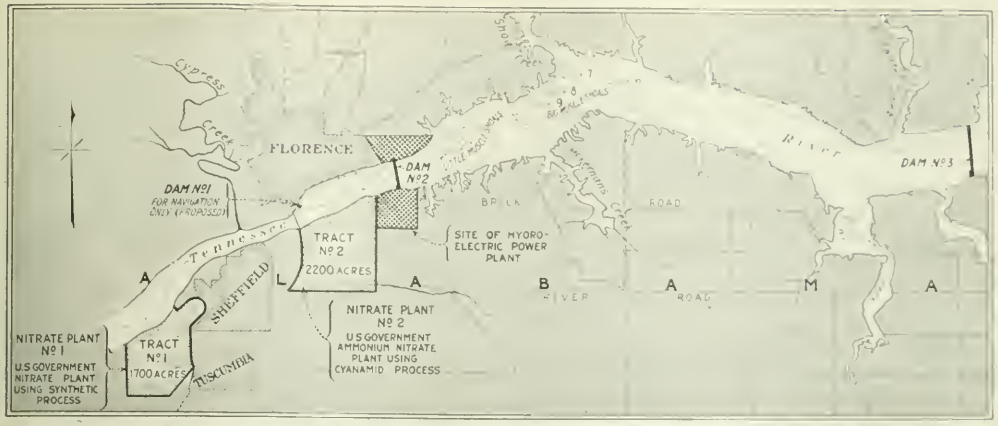


POWER HOUSE AND PENSTOCKS OCOEE NO. 2, TENNESSEE POWER CO.

Chattanooga, Tennessee

Had time permitted at this point the visitors would have found intense interest in the historic ground of Chickamauga Park, Lookout and Signal Mountains, and Missionary Ridge. Fortunately the local committee had so arranged the itinerary of the morning

[1] Reported by J. E. Shrader at the Pittsburgh meeting of the American Physical Society, December, 1917.



VICINITY OF MUSCLE SHOALS, TENNESSEE RIVER, SHOWING LOCATION OF GOVERNMENT NITRATE PLANTS AND PROPOSED HYDROELECTRIC DEVELOPMENTS

as to afford an automobile ride to these points in connection with visits to industrial plants.

The first point of interest was the plant of the Southern Ferro Alloys Co., which was opened by the courtesy of President Paul J. Kruesi and General Manager George L. Davison, both members of the Society. The company is making 50 per cent ferrosilicon at the rate of 20,000 lb. per day. The plant comprises three single-phase furnaces specially designed by the FitzGerald Laboratories. They are of 833 kw. each, or 2500 kw. for the entire plant. The maximum load for the month of April was 3800 hp. This is the first ferrosilicon plant ever opened to the inspection of visitors, and the courtesy was deeply appreciated.

The party was next taken to the Burdette Oxygen Co. for inspection of the electrolytic oxygen and hydrogen plant. The latter gas is used in the adjacent cotton-seed oil refinery of the Wilson Co. for the hydrogenation of oil.

At the plant of the Chattanooga Gas & Coal Products Co., the Society saw the operation of Semet-Solvay by-product ovens and the recovery of ammonia, tar and light oil. The finished products of the plant are coke, gas of 600 B.t.u., tar which is sold to the Lewis Co., light oil which is sold for fractionation, and ammonium sulphate.

After a trip through Chickamauga Park to a cotton mill and bleachery, the party returned to Chattanooga and went by steamer to the Hale's Bar hydroelectric plant of the Tennessee Power Co. Luncheon was served on the boat.

The dam at Hale's Bar is 1200 ft. long and about 40 ft. high. The power house, shown in accompanying view, contains 14 units of 3000 kw. each, generating current at 6600 volts, 60 cycles, 3-phase. This is stepped up to 44,000 volts for transmission to Chattanooga and 120,000 volts for Maryville, Danville and Ashville.

Returning to Chattanooga, the party was taken to Signal Mountain Hotel where a complimentary dinner was served. Interesting addresses were made by E. M. Jones and T. P. Maynard on the resources of the Chattanooga district.

Muscle Shoals District

Florence—Sheffield—Tuscumbia, Alabama

The visit to Muscle Shoals on Thursday, May 2, held unusual interest on account of the immense nitrate plants that are under construction to furnish munitions of war. Here one could gather some idea of the tremendous scale on which the Government has undertaken to provide its requirements of fixed nitrogen. Not only were the visitors impressed with the magnitude of plants, but they came away with a sense of pride in the achievements of American technologists in measuring up to the country's demands. Two huge plants are under construction, and it was learned that the nitrate program will probably call for two more of equal magnitude.

Throughout the day the Society was the guest of the Tri-City community, and members were transported by auto, boat and railroad to see the nitrate plants and the proposed hydroelectric development of Muscle Shoals on the Tennessee river.

A study of the accompanying map will give a clear idea of the full development. In the vicinity of the tri-cities are two Government reservations on which are being built the two nitrate plants, and site for the hydroelectric plant of the future. Three dams are contemplated: No. 1 for purposes of navigation only, No. 2 and No. 3 for development of power. The extent of back water is indicated on the several tributaries to the river.

Nitrate Plant No. 1

This plant is being constructed by the Government and will use a synthetic ammonia process developed by the General Chemical Co. and offered to the Government for the period of the war. A part of the ammonia will be oxidized to nitric acid, and the final product will be ammonium nitrate. Expressed in terms of nitric acid the production of the plant will be 200,000 lb. per day. As soon as the present plant is finished it will be duplicated at this point, and it is reported that a similar plant will be built for the Ordnance Dept. of the Navy. The present plant is be-

ing constructed from an appropriation of $20,000,000 made two years ago. The site was located Sept. 10, 1917; construction was ordered on Oct. 1; contracts were signed Oct. 2, and on Oct. 23 the first material arrived. There have been no labor troubles or undue delays. The number of men employed is 2500. In addition to the plant construction, the Government has also built the necessary white and negro camps, commissary, hospital, etc.

Nitrate Plant No. 2

This plant is being built by the Air Nitrates Corporation acting as agents of the Ordnance Dept., U. S. A., the personnel of the Corporation being practically identical with that of the American Cyanamid Co. whose process has been offered to the Government and is now being installed. It is understood that the proposed plants No 3 and No. 4 will use the same process.

In the auditorium of the village at Plant No. 2 the Society was addressed by Messrs. Young and Pranke of the Air Nitrates Corporation, who outlined briefly the project. Thirteen thousand men are employed and are housed in temporary camps. A permanent village will provide for 12,000 people. There is a recreation hall for each 800 men in camp, and a "movie" house each for the white and negro population. The mess hall is well organized and arranged and feeds 5000 men in 30 minutes. A modern hospital has been built and a workmen's compensation act is in effect. Sanitation is being provided in an up-to-date manner, and fire and police protection are afforded. Aparently nothing has been overlooked. These brief references give an idea of the human problems, as well as those of mere plant construction, with which the Corporation has been confronted. A complete story of the whole undertaking would make interesting reading and should be written some time in the future.

In the cyanamid plant the lime kilns will burn 350,000 tons of lime per year, and the coke dryers will handle 100,000 tons. The lime and coke are fused in carbide furnaces, the product cooled and ground and placed in ovens of one ton capacity each for treatment with nitrogen. The liquid air plant for nitrogen production will have a greater capacity than all similar plants in the United States and Canada.

The cyanamid contains 20 to 21 per cent nitrogen, equivalent to about 25% NH_3. This is cooled, ground and placed in autoclaves where it is treated with steam, producing ammonia. This gas is mixed with air and passed through a heated platinum screen, with resultant oxidation of the nitrogen by catalysis. The oxide gases are then cooled and absorbed. One-half the NH_3 produced in the autoclaves will be thus oxidized and combined with the balance of the ammonia for the production of ammonium nitrate. Power requirements will be 45,000 kw., produced from steam at the plant, and 30,000 kw. to be delivered from hydroelectric plants in the vicinity.

Expressed in terms of nitric acid the production of Plant No. 2 will be 2,000,000 lb. per day.

It is noteworthy that this entire process has been tried and proved in commercial operation for some years, and that no experimental equipment or process is being installed. As a consequence it is expected that operations will proceed smoothly from the beginning.

The construction of Plant No. 2 was determined on Nov. 26, 1917, and the first carload of material was delivered Dec. 20. Considering the short time actual construction has been under way, and the variety of work to be done, there can be nothing but admiration for the results.

J. G. White & Co. are constructing the power house at Plant No. 2 and the buildings at No. 1 with the exception of the acid plant. The Chemical Construction Co. is building the acid plants at both No. 1 and No. 2. Westinghouse Church Kerr & Co. are constructing the buildings at No. 1. Officers in charge at No. 1 are: For the Government, Capt. R. W. Hemphill; for the contractors, J. G. Munson and T. C. Oliver. At No. 2: For the Government, Capt. S. L. Coles; for the contractors, G. W. Burpee, M. T. Thompson and T. C. Oliver; for the Air Nitrates Corporation, J. W. Young.

At Lock 6, Muscle Shoals Canal

As will be seen on the accompanying map, a ship canal extends along the north bank of the Tennessee river. This canal with its nine locks, as well as considerable surrounding land and river islands, will be submerged when the proposed Dam No. 2 is built at the point shown.

It was at Lock 6 on the canal that the Society was tendered a barbecue luncheon following the visit to the nitrate plants. Here with a background of posters showing graphically the various phases of the whole Muscle Shoals project, a number of important addresses were made. C. W. Ashcraft welcomed the Society on behalf of the Tennessee River Improvement Assn., and presented Col. J. W. Worthington, who is generally known as the father of the Muscle Shoals project. He told of the long years of effort to accomplish in the South what had been done at Niagara Falls in establishing an electrochemical industry. He found a warm response to his claim that we need fewer lawyers and more engineers in Congress.

Mr. C. A. Winder addressed the Society on the subject of hydroelectric power. If power-consuming industries are not established contemporaneously with power development the latter is useless. Electrochemical and metallurgical industries offer the best load for hydroelectric plants. The speaker condemned the development of hydroelectric current for domestic and small industrial uses merely on the score that coal would be saved. Such a development might not be able to sell power enough to pay the interest on the investment which normally would be three times that for a steam plant. If the connected load does not consume power every hour of the day there is an economic waste and if it does not consume production for at least 40 per cent of the time the development is a poor venture. Domestic loads for lighting, heating, street railways and light industrial uses should be excluded from hydroelectric loads. Such loads of short duration apply to steam plants where the investment charge is small.

Mr. N. T. Wilcox of the Mississippi Power Co., Keokuk, Ia., spoke of the difficulties originally encountered in developing that project, and encouraged those in charge of the Muscle Shoals project to persevere. He said Alabama was more favored than Iowa in

mineral resources with which to foster industries that would consume power.

Mr. WILLIS G. WALDO spoke briefly on the Muscle Shoals project, stating that there could be a total development of 660,000 hp.; that the nitrate plants and other consumers would take 260,000, leaving 400,000 available for new electrochemical industry.

Mr. FUNASOHU ISOBE, chief engineer of the oil department of Suzuki Co., Japan, spoke for the Japanese who were in the party, expressing their appreciation of the courtesies shown them, and inviting the Society to Japan after the war.

After the exercises the party returned to Florence by way of railroad to Lock 9 and boat to the landing. In the evening a complimentary dinner was served, followed by an informal reception and addresses at the Elks' Home.

Birmingham, Alabama

This point in the South has long been famous for its combination of such raw materials as coal, iron ore and limestone in close proximity, and for low cost of producing pig iron. Recently the iron and steel industry of Birmingham has expanded, and the Tennessee Coal, Iron & Railroad Co. is building a model industrial town at Fairfield in connection with the new steel-plate plant. The operations of this company show that it thinks in terms of human beings as well as vast machines and furnaces.

The first point visited was the blast furnace and steel plants of the Tennessee Coal, Iron & R.R. Co. Most of the operations here were familiar to the guests, but it was a pleasure to inspect so clean and orderly a plant and see the various provisions made for the safety of the employees. The route of the party through the works was clearly marked by a trail of white sand—a convention "kink" that can well be adopted elsewhere.

From this point the party was taken by auto to the Bayview reservoir of the company, where a barbecue luncheon was served and a brief address delivered by Ex-Gov. EMMETT O'NEAL. In the afternoon the by-product coke-ovens were inspected and the new Fairfield steel works were seen in process of construction. A visit was also paid to the works of the American Steel & Wire Co., to see the manufacture of nails, barbed wire and woven wire fence. A short stop was made at the Birmingham Country Club for light refreshments, and later in the evening a complimentary banquet was served at Hotel Tutwiler.

TECHNICAL SESSION

The opening paper dealt with the mineral resources of Alabama prepared by EUGENE A. SMITH, State Geologist. Dr. Smith showed that in 1916 the value of the State's raw mineral production was $37,729,136, while the value of derived products was $55,256,735.

Electrodeposition of Manganese and Manganese Dioxide

Ten papers in all were presented at this session. The first was on the "Electrolytic Behavior of Manganese in Sulphate Solutions," by G. D. VAN ARSDALE and C. G. MAIER, respectively consulting chemist, and research chemist of the Phelps-Dodge Corporation.

This paper presents some preliminary results of work done in an attempt to solve the problem along electrochemical lines. Methods which might be developed from the results presented in this paper will probably not be adapted to the production of manganese for ferro-manganese, or other large-scale metallurgical use, but the data obtained are of interest not only theoretically but may also be of practical use for the production of manganese dioxide, particularly for dry-battery use. The results are summarized by the authors as follows:

(A)

1. Mn may be deposited at the cathode, from neutral solutions with high-current efficiency, from 80-90 per cent, and at voltages from 3 volts up.
2. The effect of increase of acidity is practically to prevent the deposition of Mn at a concentration of 0.36 per cent free H_2SO_4.
3. The deposit is powdery, and ordinary expedients for improving deposition do not give better results to any great extent.

(B)

1. MnO_2 may be deposited at the anode at nearly 100 per cent efficiency.
2. The effect of acid is to decrease the efficiency in cold solutions, but on heating to 65 -75° C. there is very much less effect.
3. MnO_2 may be deposited from warm acid solutions containing more than 5 per cent MnSO, in the form of a dense, black, lustrous film, at current densities up to 25 amp. per sq. ft. (275 per sq. m.) with very high deposition efficiency.
4. Impurities which are reducing agents cause a decrease in current efficiency in proportion to the amount present. Methods of controlling practically the effects of deleterious impurities and the possibilities of a commercial method of treating low-grade ores, and producing a high-grade MnO_2, will be the subject of a later paper.

Electrolytic Copper

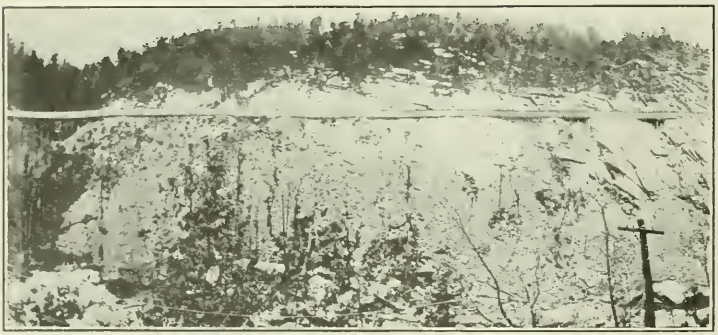
The effect of iron sulphate in the electrolytic precipitation of copper from sulphate solution with insoluble lead anodes was discussed in a paper by Prof. EDWARD F. KERN of Columbia University. He found that the presence of iron reduces the efficiency in the electrolytic precipitation of copper from sulphate solutions, when insoluble lead anodes are used. The higher the percentage of iron in the electrolyte, the lower is the current efficiency, and vice versa. The smaller the amount of copper in the electrolyte, the greater is the reduction of current efficiency as the result of the presence of iron sulphate in the solution. The effect of temperature upon the deposited copper is that smoother and purer copper is formed at 50 deg. C. than at lower temperatures. When no iron is present in the electrolyte, the copper may be almost completely removed, and the current efficiency remain very high, even though the copper in solution may be reduced to as low as 0.2 gram per 100 cc. Iron in the copper sulphate electrolyte causes the copper to deposit less smooth and less dense, irrespective of the ratio of current density at anode to that of cathode. It was seen that less adherent and less dense copper was deposited on the cathode from the electrolytes which contained iron than from electrolytes which contained no iron

and which also contained far less copper. The effect of the presence of iron in the electrolyte is to reduce the voltage required for the electrolysis. When no iron was present the potential between anode and cathode was approximately 2 volts; whereas when iron was present it was lower, in most cases being approximately 1.8 volts.

Copper Electroplating

Experiments with the copper cyanide plating bath were described in a paper by Prof. FRANK C. MATHERS of Indiana University. It was found that the current-yields (ampere efficiencies) at the cathodes were generally lower than those at the anodes, hence the necessity of making the regular additions of sodium cyanide to the baths. Sodium carbonate and perhaps sodium sulphate are valuable additions to the bath. In baths containing near to the minimum of sodium cyanide, sodium hydroxide lowered both the anode and the cathode yields. The anode yields are high in both hot and cold solutions if a proper quantity of sodium cyanide is present, but the cathode yields are much lower in the cold solution than in the hot. A bath containing 6 oz. (4.5 per cent) copper cyanide, 5.7 to 6.3 oz. (4.3 to 4.7 per cent) sodium cyanide and 5.8 oz. (4 per cent) sodium carbonate per gallon operated at 160 deg. to 175 deg. F. (60 to 80 deg. C.) is recommended. This is more concentrated than the baths generally used, but it can be operated at a higher current and the deposits are much better.

Mr. G. B. HOGABOOM criticized the high temperature used, stating that the deposits would be brittle and unsuited to work where bending or soldering were necessary. Furthermore the decomposition of cyanide is too great at 180 deg. F. As to the concentration of solution used by the author, he felt that 3 oz. Ag per gal. would give better results than 6 oz. The latter solution would be certain to yield blisters if used on steel. As for addition agents, NaOH is useless; Na_2CO_3 is useful to "age" the solution, but once added must not be added again. In fact it will increase with time, and hot solutions tend to accentuate this result. At 180 deg. F. a solution will increase from 11 deg. to 30 deg. Be. in three months. He was quite certain that the author's recommendation of a solution containing 5.3 ounces of sodium carbonate per gallon would not give good commercial results as far as the deposit is concerned.



FLUME, OCOEE NO. 2, TENNESSEE POWER CO.

Magnesia-Silica Refractories

The results of tests on the "Crushing Strength of Magnesia-Silica Mixtures at High Temperatures," were described by Prof. O. L. KOWALKE and O. A. HONGREN, of the University of Wisconsin. The mixtures were made from magnesia running 99.92 per cent MgO and silica running 97.66 SiO_2, the balance being lime, iron oxide and water. The mixtures were moistened and pressed into cylinders in a hydraulic press under a pressure of 1500 lb. per sq. in. They were then dried at 2100 deg. C., cut to 1 in. diameter and put under a uniform static load of 66.5 lb. per sq. in. and heated at a uniform rate until they failed. The general summary of results follows:

Pure magnesia failed under a load of 66.5 lb. per sq. in (4.65 kg. per sq. cm.) at 1,680 deg. C.

The addition of silica to magnesia, with seven to eight per cent silica as a maximum, increased the mechanical load-carrying capacity, so that failure occurred only at about 1870 deg. C., which is approximately 190 degrees higher than magnesia supported.

The failure of magnesia cylinders is slow and gradual; that of magnesia-silica cylinders is abrupt.

The superiority of magnesia-silica mixtures with 7½ per cent silica, over pure magnesia, in mechanical load-carrying capacity, appears to be due to the envelope of forsterite, which cements the grains of periclase.

Above 2000 deg. C. carbon attacks magnesia-silica mixtures very rapidly with a marked loss in weight.

Electrolytic Tin

A record of experiments to determine the best electrolyte, the best current density and the best addition agent to use in electro-refining impure tin bullion, with the object of saving the precious metals and getting pure tin was given by Prof. EDWARD F. KERN of Columbia University.

The experiments upon which this paper is based were conducted by Mr. FAN CHEN in the Electrometallurgical Laboratory of the School of Mines of Columbia University. The work was undertaken with the idea of finding a suitable tin electrolyte, and the proper working conditions for electrolytically refining tin bullion, so as to obtain the tin as an adherent, dense, compact cathode deposit.

The anodes were crude tin, cast into thin plates 4 inches (10 cm.) long, 1¾ inches (4.4 cm.) wide, and ⅜ inch (0.94 cm.) thick. Analysis gave (in per cent) 96.0 tin, 0.5 iron, 0.1 arsenic, 0.2 antimony, 2.0 lead, 0.6 copper, 0.1 bismuth, and 0.5 silver. The cathodes were made of sheet tin 1/64 inch (0.4 mm.) thick, and larger than the anodes by a quarter of an inch (0.6 cm.) on each of the two edges and bottom.

The electrolytes which were selected for trial were solutions of stannous chloride ($SnCl_2$), sodium-stan-

nous chloride ($SnCl_2.2NaCl$), ammonium-stannous chloride ($SnCl_2.2NH_4Cl$). Magnesium-stannous chloride ($SnCl_2.MgCl_2$), sodium-stannous fluoride ($SnF_2.2NaF$), stannous fluosilicate ($SnSF_6$), and a mixture of acid solutions of stannous fluoride and fluosilicate. Each of these solutions was prepared to contain 5 grams of tin per 100 cc. The experiments led to the following conclusions:

Addition agents are necessary for the electro-deposition of dense adherent deposits of tin.

Stannous fluosilicate electrolyte is the best of the electrolytes tried for the electrolytic refining of crude tin. Free hydrofluoric acid and free hydrofluosilicic acid are beneficial; HF 60 per cent of the total acid content is not detrimental.

The deposits of tin which are formed in sodium-stannous chloride, ammonium-stannous chloride, and stannous chloride electrolytes are similar, when addition agents are present.

Aloin was found to cause the formation of the best deposits when added to stannous fluosilicate electrolytes, in amount corresponding to 1 gram per 500 cc. of electrolyte.

Peptone, when added in amount of 1 gram per 500 cc. of electrolyte, gave good deposits from all of the electrolytes reported in Tables II, III, IV, and V.

Gelatine, quinoline and oil of cloves, when present in amounts of 1 gram per 500 cc. of electrolyte, did not improve the deposition of tin, except in the case of the stannous fluosilicate electrolyte.

Boric acid, when added in amounts of 1 gram per 1500 cc. of electrolyte and up to the saturation point, did not improve the electro-deposition of tin, except when added to stannous fluosilicate electrolyte in amount corresponding to 1 gram per 1000 cc. of solution.

Mr. WITHERELL sounded a note of caution against the use of addition agents, saying that they frequently worked well for a while, but that after a few weeks trouble would come, due to the decomposition of the agents, particularly those of organic nature. These troubles cannot be discovered in the laboratory, and hence it is advisable to use addition agents in only part of the plant at any one time.

Rusting of Rails

Under the title "Why Busy Rails Do Not Rust," Prof. OLIVER P. WATTS, of the University of Wisconsin, reviewed at length observations made since 1843 on the fact that idle rails appear to rust faster than busy ones. He gave the following explanations offered by previous writers for the lessened corrosion of rails in use:

1. That vibration causes shedding of rust and so, in the presence of less of this stimulator of corrosion, rusting will be diminished.

2. That vibration breaks up areas of different potential that are naturally present on the surface of iron or steel.

3. That there is a voltaic action between bright or polished and dull or rough iron which, in some manner not explained, lessens the total corrosion of the rail.

4. That the rise in temperature produced by the passing of trains causes a more rapid evaporation of moisture from the used rails, and for this reason lessens corrosion.

Prof Watts' results showed that an e.m.f. exists between the top and other portions of used rails acting in such a direction as to protect the rest of the rail; but it is manifestly impossible that a current generated by corrosion of one part of a bar of metal in a single solution shall, by its protective action on the other part, lessen the total corrosion.

The author presents the view that the lessened corrosion of rails in use is due to a combination of two of the causes mentioned by previous writers, viz., voltaic action between strained and unstrained metal in the rail, which results in a slower formation of rust on the cathodic portions, and that thereby the normal accelerative action of rust is greatly diminished; and the complete removal of rust from the top of the rail, where it would otherwise form most rapidly and exert the greatest accelerative effect on rusting.

Electric Furnaces

The **Vom Baur arc furnace**, a new design, was described by C. H. VOM BAUR, consulting engineer of New York City. The furnace is particularly designed for melting ferromanganese or ferrosilicon, or melting down cold charges for steel castings. The furnace design was created after observing many different electric furnaces in operation, and also operating many of them. It is covered by U. S. Patent No. 1,252,633, and was designed to remedy several defects of previous arc furnaces of the simpler, polyphase, solid bottom type.

It has a 2-phase, 3-wire connection, with the three electrodes in a straight line, the center electrode carrying the heavier current, all contained in an oval-shaped hearth, which has an equal heat gradient at the slag line. As the design follows easy, natural lines, furnaces as small as ½-ton and as large as 15 tons are now being made. In the larger furnaces, the rolling features of the Wellman type have been adopted, whereas with some of the smallest the tilting is accomplished, keeping the spout almost stationary, by having the fulcrum directly beneath it, which facilitates pouring into small hand-ladles.

The advantages of this shape of hearth, together with the 2-phase, 3-wire connection, and the electrodes in a straight line, are claimed to be many and far reaching. For instance: when burning in a basic bottom, as the electrodes are in a straight line, the heat of the arcs can be transmitted to a scrap carbon electrode lying horizontally on the bottom directly beneath all three vertical electrodes, and thence to the basic layer being sintered. Whereas, with arc furnaces having their three electrodes placed in triangular form, or those using four electrodes in a rectangular form, two carbon blocks at least are necessary in order to bring the electric arcs into play for sintering in the bottom. Other advantages in melting down and in minimizing heat losses were explained.

The **Booth-Hall electric furnace**, also a new design, was described by W. K. BOOTH, general manager of the Midland Electric Steel Co., Terre Haute, Ind. It is a vertical arc furnace with conducting hearth and

is built either single-, two-, or 3-phase to suit the conditions at the place of installation, the general principle being a furnace having a solid hearth which becomes conductive of electricity when hot, and the use of an auxiliary electrode which acts as a return for the electric current until the hearth becomes heated and conductive. The furnace is particularly

INTERIOR OF FLUME FOR OCOEE NO. 2, TENNESSEE POWER CO.

intended for melting down cold charges for steel-casting foundries. An illustrated description was published in METALLURGICAL AND CHEMICAL ENGINEERING, February 15, 1918, page 211.

Electric Steel Castings

A continuation of a report of foundry experience making electric steel castings was given by R. F. FLINTERMAN, of the Michigan Steel Castings Co. The former report was read at the Detroit meeting in May, 1917, and was published practically in full in our issue of May 15, 1917. In this paper a process referred to as "reversed duplexing" was mentioned as having great possibilities and it was intimated that this process would be tried out. In the present paper Mr. Flinterman says the process has not been tried out, as they have been able to increase their tonnage to such an extent with their present furnace that the addition of another furnace would not be economical. An inspiration for a change in furnace construction was derived from the paper by A. A. Meyer on "Electrical Characteristics of Electric Furnaces," which was also presented at the Detroit meeting in May, 1917 (see this journal, May 15, 1917). In this paper several causes of high-voltage drop in the bus bars were discussed and these were made the basis of changes in Mr. Flinterman's Heroult furnaces.

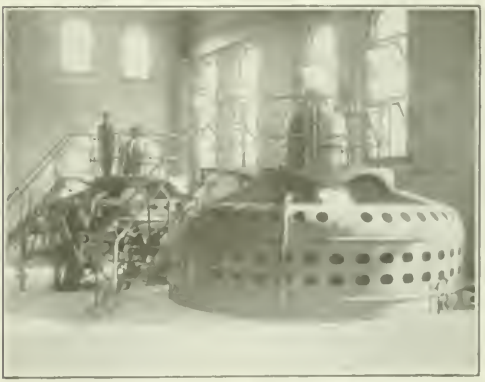
We quote from his paper as follows:

"In case of both the bus bars between the transformers and the flexible cables, and also the bus bars on the furnace itself, the $\frac{1}{4}$ x 6 in. (0.6 x 15 cm.) copper bars were spaced by means of $\frac{1}{4}$ x 3 x 6 in. (0.6 x 7.5 x 15 cm.) copper spacers. These spacers have all been replaced by vulc-asbestos spacers. In addition, mica insulation was placed between the various bus-bar leads in such a way that the different parts were isolated and made to act as nearly as possible independently from one another. We find that these small changes have made a great change in operation of furnace. From all indications it would appear that the drop in voltage found by Mr. Meyer has been much reduced. This point will be more clearly established by a series of tests which will be undertaken in the very near future.

"At any rate, it is safe to asume that part of the drop was due after all to skin effect, and that it was not entirely due to induction set up in the steel construction at rear and top of furnace, as Mr. Meyer stated in his paper.

"Under the circumstances, it would be much better to do away with the solid bus construction entirely. The later Heroult furnaces are now constructed as is our 3-ton furnace, where the flexible cables are carried direct to the upper part of the steel structure at back of the furnace. It would seem even better to us to carry the flexible cable directly through to the electrode clamps. There would of course be some induction set up in the steel structure, but we do not believe there would be as much voltage drop as there is now. At any rate, as now constructed, our furnaces are running much faster than formerly, and our current consumption is regularly lower than it was before. On one run of 24 hours, 11 heats were taken from the 3-ton furnace. Our average current consumption for the week, including all delays and stops, is running under 625 kw. hours per ton. Since our work is light, and our metal must be brought to a very high temperature, we consider this a very low consumption.

"With our tonnage brought to this high figure, our floor capacity is taxed to the utmost. An additional furnace would therefore be superfluous and uneconomical. The only opportunity for 'reversed duplexing' in our own shop would be to change the 3-ton furnace to basic lining. Under present pressure of



GENERATORS, OCOEE NO. 2, TENNESSEE POWER CO.

work this is of course impossible, and the actual trial of duplexing must therefore wait.

"There is one other point referred to in the writer's former paper which I desire to touch upon here, namely, the great possibility of the electric furnace in production of the various steel alloys. This one feature is perhaps of greater value and interest to the makers of tool steel, but I am firmly convinced that there are wonderful possibilities in the manufacture of heat-treated alloy-steel castings. This is

a field which is almost untouched and is well worth investigating.

Owing to lack of time the following papers were read by title only:

Brittleness Produced in Steel Springs by Electroplating, by O. P. WATTS and C. T. FLECKENSTEIN.

Experimental Carbon Cell, by S. A. REED.

Methods for Commercial Analysis of Ferrosilicon, by E. M. ANGER.

Thermoelectric Force of Some Alloys, by M. A. HUNTER and J. W. BACON.

Anniston, Alabama

This city was interesting from a technical point of view on account of the manufacture of electric ferroalloys and electric pig iron from scrap.

The Society was entertained at breakfast at the Anniston Inn, after which Mr. THEODORE SWANN, President of the Southern Manganese Corp., outlined the technical features of the local plants. The Southern Manganese Corp. is operating eight 3-phase furnaces on ferromanganese, and in April produced 5 per cent of the United States output. The Anniston Steel Co. is producing pig iron from steel scrap melted in 6-ton Heroult furnaces. Three additonal furnaces of the Southern Manganese Corp. have been leased to another company, which is making ferrosilicon.

Mr Swann stated that they expect to mine all their manganese within eight miles of Anniston and produce 8 per cent of the United States output. They are not looking for bonanzas and expect to get their supply in small lots from mines equipped with one or two log washers and producing up to 10 tons per day each. Such

DAM AND POWER HOUSE, OCOEE NO. 1, TENNESSEE POWER CO.

properties can be equipped for $2000 and will be ahead of the game when they have shipped their third carload of ore. Taking the cue from former practice of washing five tons of brown iron ore to get one ton of product, Mr. Swann believed they can afford to wash 50 tons of manganese dirt for one ton of 40 per cent manganese concentrate.

At present the slag from the electric furnaces is being sold to blast furnaces for recovery of the manganese content. Experiments on the retreatment of slag in the electric furnace showed that from slags containing 12 to 14 per cent Mn it was possible to produce a 60 per cent ferromanganese at the third or fourth tap, but the procedure was not commercially profitable. Silicomanganese has been made from the slag pile, running 69 per cent Mn and 19 per cent Si. The product requires more than three times the power necessary for ferromanganese. The furnaces used in the old plant are the type of carbide furnaces of the early nineties. Con-

HALE'S BAR POWER HOUSE, TENNESSEE POWER CO.

struction of the new plant was begun on June 25 and was turning out ferromanganese in 23 days. Mr. Swann stated that the company is willing to impart information to anyone who can use it for the benefit of the Government at this time. The plant had thus been opened to the engineers of the Anaconda Copper Co., which recently prepared to make ferromanganese at Great Falls, Mont.

RETURN TO WASHINGTON

The special train left Anniston Saturday noon and arrived at Washington Sunday afternoon, where the party disbanded and returned to their homes. The meeting and trip was one of the most successful affairs ever undertaken by a society and was pronounced the best of the meetings of the American Electrochemical Society. It was no junket undertaken for pleasure or personal profit alone, and if the report of the proceedings is replete with items of entertainment, that is to be charged to the inevitable Southern hospitality which had to find expression even in war time. The presence of a dozen ladies in the party added to the pleasure of the tour. They were specially received and entertained at every stop.

The trip was a hurried reconnaissance of a remarkable territory and the sentiment was frequently expressed that a future meeting should be held in the South at a central point. For the excellent arrangements of the trip the Society is indebted to Mr. Charles F. Roth and his committees at the points visited.

Iron and Steel of Canada.—We are glad to welcome a new member to the ranks of metallurgical journalism in America in *Iron and Steel of Canada*, a monthly publication appearing in Montreal in February. The high quality of the publication can be inferred when it is known that Alfred Stansfield, professor of metallurgy of McGill University, is editor in chief. Its field is "the science and practice of the iron, steel, foundry, machine and metal-working industries."

The Future of the American Electrochemical Industry

By S. W. Maher*

IT IS well known that the present center of the electrochemical industry in this country is in the Niagara Falls district, and that the situation there as regards an adequate power supply for the future development of this industry is becoming a very serious problem. In view of this fact it is doubtful if Niagara Falls will remain the center of this industry. Even if it should remain the leading electrochemical district of this country, it is evident that new sources of power must be found to take care of the expansion and development that is already beginning to tax the capacity of the power plants at Niagara Falls. The recent phenomenal growth in the demand for products manufactured by the electric furnace makes the question of great interest to the American engineer and manufacturer.

It is true that the war has brought about an unprecedented demand for electrochemical products, but it is not believed that the industry will decline to any great extent with the cessation of the war. On the contrary, the products of the electric furnace and of electrolysis depend for their demand largely on the ordinary and general growth of industry in this country. The truth of this assertion is easily seen when the chief products made with the help of electric current are considered.

The production of machinery is depending more and more on artificial abrasives, which are important products of the electric furnace. In fact, the value of artificial abrasives is already greater than that of natural ones. Of great importance also are the special alloys used for cutting metals at high speed, and the special steels of various kinds used in so many of the machines that are manufactured today. Aluminium, whose consumption is growing rapidly, and whose uses are just beginning to be understood, is entirely an electric furnace product. Mention may also be made of the electric production of steel, the production of calcium carbide for cutting and welding purposes, and the production of such metals as calcium, magnesium and sodium.

The products of electrolysis in solution are chlorine (which is of the utmost importance to the dye industry), oxygen, caustic soda, and the electro reduction of aromatic nitro compounds. This latter offers a field of great promise as it has yet been little worked on a commercial scale. With the present scope and importance of electrochemical industry, and its future requirements before us, it is proper to refer again to the situation at Niagara Falls. As already stated, this is the center of this field of work in the United States, and as such it is a vital factor to other industries scattered over the country. For instance, the cutting off of abrasives from this point would seriously cripple if not utterly destroy our airplane industry. If continued much longer the apparent lack of appreciation of the importance of the stable and growing electrochemical industry will make itself felt in no uncertain manner. It is believed, with no fear of contradiction, that there is not enough power available at Niagara Falls to adequately support the increasing demand of some of our most important electrochemical industries.

Canada is in a position to control the greater portion of the power supply at Niagara Falls, and in fact has been selling the American manufacturers a considerable quantity. Already, however, Canada's needs are increasing rapidly, and she is, therefore, forced to cut off our supply. As her demands continue to grow, the power situation must become more and more acute for us. In view of these facts, the American electrochemical industry must find other fields where it can expand and grow to meet the requirements of our industrial development.

The ideal site for an electrochemical industry should have not only cheap electric power, but certain raw materials such as salt, lime, coal, bauxite, iron manganese, chrome and nickel. There should also be adequate facilities for assembling the raw materials and distributing the finished products to the market. Of special importance, although not absolutely necessary at the point of production, are such materials as are necessary in the construction and maintenance of electrochemical plants. Among these may be mentioned fireclay, asbestos and mica, as well as refractory materials of all kinds.

Having shown the necessity for seriously considering at this time the future of the American electrochemical industry, attention is now called to a section of our country that we believe offers exceptional advantages for electrochemical plants. We refer to that portion of the southern Appalachian region that lies between the Cumberland Mountains on the north and the Blue Ridge System on the south, and comprising parts of Southwest Virginia, East Tennessee and Western North Carolina. This region offers great advantages in water and steam power, raw materials for manufacturing and building, and has good transportation facilities.

The territory is drained by the waters of six rivers, namely: the Powell, Clinch, Holston, Nolichucky-Toe, Wautauga and French Broad. The primary sources of these rivers are found in the springs, which are supported by abundant rain fall. The rainfall in this part of the country is so heavy and so uniformly constant from year to year that a constant and never failing supply of water power is assured at all times.

The approximate indicated minimum horsepower of these rivers is: Powell 13,000 hp.; French Broad 132,000 hp.; Nolichucky-Toe 61,000 hp.; Wautauga 30,000 hp.; Clinch 34,000 hp.; Holston 47,000 hp. This gives a total minimum indicated horsepower of 328,000. It should be understood that the above figures do not include storage, or any of the tributaries of these rivers.[1]

In addition to the water powers mentioned above, this territory is well situated with respect to the coal fields of Kentucky, Virginia and Tennessee. The amount of coal available from these fields is shown to some extent by the tonnages produced in the respective states in the year 1915. In this year Virginia produced 8,000,000 tons, Kentucky 21,000,000 tons, and Tennessee 5,000,000 tons.[2] These fields possess ample reserves,

*Chemist-Geologist, Carolina, Cinchfield and Ohio Railway.

[1] These figures are taken from "The Water Powers of Tennessee" by J. A. Switzer.

[2] From "Resources of the United States," by the United States Geological Survey.

and are tapped by railroads with strictly modern equipment. This assures a cheap and large supply of first class bituminous coal, which can be transported to prospective plant locations on a very low freight rate.

The mineral resources of this region are very extensive and will furnish many of the raw materials necessary to the electrochemical industry. These minerals are situated on or near the railroad, and, therefore, are easily assembled at points of manufacture. Southwest Virginia offers coal, salt, silica sand and high-calcium limestone, as well as iron and manganese. East Tennessee has commercial deposits of iron, manganese, phosphate and bauxite. Western North Carolina has low phosphorus magnetite, brown hematite, titanic magnetite, nickel and chrome. The proximity of these deposits to the railroad and water powers make the problem of assembling this material a very simple one, and, furthermore, excellent and quick freight service is available for distributing the finished products to the markets of the East, North, South and West.

Building material occurring and produced in this region are Portland cement, brick, tile, sand, lime, granite, sandstone and a variety of timbers, both hardwoods and softwoods.

Other materials that are found in this territory are asbestos, mica, fireclay and other refractories. The hardwoods found so abundantly in this territory are a source of charcoal and acetone, which are of great value. A large wood alcohol plant is now being constructed.

Hence, it is evident that the Southern Appalachian territory offers an interesting field for closer investigation by the electrochemical engineers. It has the necessary factors for cheap power; is has the raw materials, the assembling and distributing facilities, the building material and other advantages of importance to the electrochemical industry.

Johnson City, Tenn.

Approximate Determination of the Minerals in Concentrates by Means of the Microscope

By Kirby Thomas and Frederick W. Apgar

MICROSCOPIC examination of the concentrates and tailings from preliminary laboratory and mill tests furnishes a ready means of checking operations and observing the results of various adjustments and modifications of process during experimental work. Large-scale mill operation may thus be instituted along most promising lines, avoiding the chance of any radical later rearrangement of plant at considerable cost or the abandonment of a plant which in practical operation was found totally unfitted to the ore at hand. Such examples of wasted expenditure may be found in almost any mining district.

A simple and rapid method for obtaining an approximately accurate quantitative mineral analysis of a concentrate by means of the microscope gives immediate results when they are most wanted, whereas a complete chemical analysis with the calculation involved for recasting in terms of minerals requires considerable time and expense and the results are often delayed until after the immediate necessity for them is past.

A portion of the concentrate which has been reduced in bulk carefully by the application of approved methods of sampling is taken, spread out evenly on a glass microscope slide and placed on the stage. A magnification of 30 to 60 diameters is generally found sufficient for this purpose. The number of grains of each of the various minerals within the field of the microscope may then be counted, at the same time noting the general average size of grain for each.

This operation is repeated from five to ten times over the slide at random points and the results tabulated. Three or four slides may be prepared if desired and two to three counts made on each. If all the grains are approximately equal in size, the *total* number of grains counted of each of the various minerals, reduced to parts per hundred, will represent a percentage *volume* analysis directly; otherwise a simple correction must be applied to allow for the difference in grain-size of the various mineral components.

The relative volume so obtained multiplied by specific gravity and again reduced to parts per hundred will give the desired weight percentage of the different minerals and will be found sufficiently accurate for most practical purposes. The method will take considerably less time than would be required for chemical analysis recast in terms of mineral percentages.

In most cases it will be found that the critical minerals in fragment are easily distinguished by color and surface appearance so that the count may be made very easily and quickly. Certain gangue minerals such as quartz and feldspar are classed together and where two similar appearing dark sulphides occur together in an ore it is not generally necessary to distinguish between them. As a rule milling problems are concerned with the relative proportion of sulphides, oxides, silicates or carbonates and gangue, or with sulphides which differ materially in appearance and gangue.

If a large proportion of the grains are complex in character, minerals included in gangue, the approximation will be less accurate but at the same time perhaps this very fact is of the utmost importance as suggesting the desirability of finer grinding.

TABLE I—MICROSCOPIC ANALYSIS OF FLOTATION CONCENTRATES

Counting all grains in field over 0.03 mm. in size
Considerable dust-like particles from 0.001 to 0.003 mm.
Grains of the different constituents average fairly uniform in size.
Green mineral slightly smaller and quartz slightly larger than the black metallic.

	No. Grains	% Area	No. Grains	% Area	No. Grains	% Area	No. Grains	% Area
Green transparent (Chrysocolla) Size 0.03 to 0.12 mm.	72	38.0	48	34.0	57	34.0	84	43.0
Quartz Size 0.04 to 0.20 mm.	46	24.0	36	26.0	32	19.0	40	21.0
Brown transparent Size 0.1 mm.	1	0.5	1	0.7	1	0.6	1	0.5
Red transparent (Cuprite) Size 0.03 to 0.08 mm.	2	1.0	0	0.0	2	1.0	2	1.0
Black Metallic Size 0.03 to 0.17 mm.	70	37.0	48	34.0	73	43.0	64	33.0
Bronze to yellowish Size 0.08 to 0.15 mm.	0	0.0	7	5.0	3	2.0	4	2.0
		100.5		99.7		99.6		100.5

A typical example of the results obtained by this method on concentrates from a flotation experiment is given in Table I. The approximate results would indicate that by bulk the copper minerals in the concentrate were about 79 per cent, distributed as indicated, which by calculation would show a weight content for the concentrate of copper minerals of from 85 to 90 per cent. Further calculation if necessary will indicate the metallic content.

Milling in Cyanide Solution

A Comparative Analysis of the Results of Milling Gold and Silver Ores in Cyanide Solution in Place of Alkaline Water; and the Relation of Amalgamation in the Selection of Method

By A. W. ALLEN

THF object of the present article is to bring forward the pros and cons of milling in cyanide in place of alkaline water as a diluent of the ore and pulp in wet-crushing and grinding operations.

One of the chief advantages accruing from the practice of milling in cyanide solution is the intimate contact resulting between coarse metal and solvent, caused by the action and operation of the grinding machinery. This advantage shrinks in importance in the case of amalgamable ore when consideration is paid to the fact that milling in cyanide precludes the possibility of amalgamation being practiced, or renders its function only partly effective if any quantity of the metal in an ore can be obtained by a simple and direct method an explanation is needed for the substitution of a complicated solution alternative which actually recovers only a proportion.

In the case of gold ores and in spite of clear enunciations of the actual facts disclosed by milling results a good deal of misapprehension exists; and the question has been complicated and the issue beclouded by reference to the efficiency of amalgamation with unamalgamable gold ores. Such considerations do not affect the question. If a proportion of the gold in an ore is amalgamable then practically 100 per cent of this proportion is recoverable. If cyanidation replaces amalgamation as a treatment process for this proportion, then only from 90 to 95 per cent is usually recovered.

The arguments advanced in favor of part amalgamation have, as far as I am aware, only been used as referring to amalgamable gold; and it is therefore an untenable claim to advance that this gold may not amalgamate. In special but exceptional cases the recovery of gold by cyanidation may reach 97 per cent, but in no single instance has a recovery of 100 per cent been recorded with any professional claim to verisimilitude. These facts may be substantiated by milling barren material similar in physical characteristics to the ore usually found in gold treatment plants, and mixing with this a proportion of coarse gold recovered by the amalgamation process. No matter how fine the ultimate division of the mixture there will remain a small percentage of the original amount of gold associated with the gangue after complete milling in cyanide and filtration treatment.

Extraction Versus Recovery

A second method of beclouding the issue is to draw attention to the total amount of gold dissolved or extracted by cyanide and to ignore the question of recovery. Finely divided gold may be completely dissolved in a cyanide solution and thus completely extracted from the ore; but when associated with gangue as an average grade material such extracted gold cannot be completely recovered by any combination of known metallurgical processes operating on a working scale. All or nearly all the gold may be dissolved and a high percentage may be recovered as bullion. The loss of the balance is all that is needed to influence the contention in favor of efficient amalgamation of gold ores.

A case in point is afforded by the recent publication of the results of treatment in a milling-in-cyanide plant where amalgamation has been abolished. Previous milling operations showed that 86 per cent of the gold could be concentrated in about 7 per cent of the tonnage. Tests on the 93 per cent remaining, constituting the tailing after amalgamation and concentration, showed that this could be reduced to 45 cents per ton by crude cyanide methods, and apparently without further grinding expense. These results would seem to indicate the lines along which a very successful scheme of treatment might be formulated.

The 45-cent residue was, however, considered discouraging and further experiments on a sand of normal fineness for leaching purposes were apparently not considered. Tests were then made to see how much gold could be dissolved by an agitation treatment, and the results indicated that all the gold was soluble provided grinding was carried far enough. "Extractions" of 99.7 per cent were obtained in the laboratory; and as a result of these tests it was decided to grind and regrind the 7 per cent of the concentratable material without separation from the 93 per cent of low-grade ore, a scheme which provided that every particle of worthless rock and absorbent colloid should be thoroughly accepted in as rich a solution of gold as possible.

The fact that all the gold is soluble in cyanide is now reaffirmed, but actual results would seem to indicate that from 40 to 50 cents per ton has been lost in the residue from about 400,000 tons treated by an all-sliming, milling-in-cyanide process.

If the question of the further recovery of gold from the residue is considered it must be realised that the 7 per cent of material which might have been concentrated for special treatment is now intimately mixed with a large tonnage of gangue, and that any additional treatment of this residue may be deemed infeasible by known methods of handling. Even if the ratio of concentration was reduced to 10:1 there would still remain argument in favor of the isolation of the special product. A dump of 400,000 tons of residue carrying about 40 cents per ton in gold is valueless. A dump of 10,000 tons of clean pyritic concentrate carrying about $2 per ton in gold is a valuable asset in sulphur content as well as gold.

Tests on the concentrate in question showed that 96 per cent of the gold could be extracted by straight cyanidation, and apparently without previous roasting, or amalgamation during regrinding. Practical results on pyritic concentrate invariably show that roasting reduces the cost of subsequent grinding and leaves

cyanide consumption. Sulphur is urgently needed at the present time but "up-to-date" methods for the treatment of a simple gold ore involve not only the loss of the pyrite but a recoverable percentage of gold associated with it. By concentrating the pyrite and recovering the sulphur the gold is actually liberated, and the highest possible percentage may then be recovered.

The foregoing example adds weight to the contention that after milling in cyanide and all-sliming the actual residue value is not by any means in inverse ratio to the solubility of the gold in cyanide solution; but rather in direct ratio to the amount of gold which is permitted to pass into solution and become intimately associated with the worthless constituents of the ore. Practical results go to prove that a comparatively high percentage of such soluble gold is lost in the residue after what are generally termed "improved" methods of ore treatment.

Influence of Colloids in Absorption of Metal

Absorption of dissolved metal by colloid particles plays an important part in the all-sliming process and may be cited as one reason at least for the non-recovery of all the extracted metal. It is no longer possible, in the light of contemporary investigations, to speak definitely of dissolved or undissolved metal after cyanide treatment, when it is impossible to determine how much of the metal has been dissolved and absorbed, and how much has been untouched by the solvent. Reduction in actual recovery as a result of the absorption of metal-bearing solution is a phase of treatment not encountered in amalgamation practice. Absorption and adsorption are phenomena which are largely influenced by the question of fineness of division; and this fact may serve to explain the reason for the comparatively high residual content after milling and fine grinding in a cyanide solution carrying valuable metal, or in which a proportion of the metal is immediately dissolved.

Amalgamation Inefficient for Silver Ores

In the case of silver ores the advantages are in favor of milling in cyanide and the abolition of amalgamation, other than in exceptional cases such as at Nipissing. The reason is that on normal grade ores amalgamation is an inefficient process at best, a circumstance largely due to the fact that the specific gravity of the metal is comparatively low, and also that it invariably occurs in combinations unfavorable to high extractions by this process.

An additional factor influencing the decision to abolish amalgamation in favor of milling in cyanide with silver ores is found in the circumstance that the finest grinding is necessary in any case, whereas with gold ores it is almost invariably unnecessary, although often adopted to eliminate the need for separate treatments of sand and slime and to simplify the subsequent methods by handling the pulp in one solution and solution-displacement operation.

If regrinding of mill pulp could be done after thickening there would be a field for usefulness in the tube-mill in helping to dissolve gold remaining associated with the ore after efficient amalgamation had recovered its maximum amount. But efficient milling and regrinding usually involves classification and ample dilution, hence milling in water and regrinding in solution is impracticable under ordinary circumstances.

Dry Crushing Precedes Roasting and Cyaniding

Dry crushing is usually practiced from necessity and not from choice, but this method of reduction is indicated in the case where roasting follows crushing and precedes cyanide treatment. In this instance it has been found an advantage to regrind in weak cyanide solution in an apparatus available for amalgamation. The cyanide present tends to cleanse the gold and assist amalgamation; and as much as 40 per cent of the gold content in refractory ore may be recovered by this method at a minimum cost for labor and material, the balance being in a favorable condition for subsequent cyanide treatment.

Water Consumption Influences Method of Treatment

On the question of water consumption there are advantages in favor of milling in cyanide in those cases where efficient thickening is out of the question, or where the residue is discharged at under 20 per cent moisture. Under normal conditions, and by inexpensive means, sand tailing may be dewatered to carry the same percentage of moisture as when being dumped. Slime pulp can usually be dewatered by gravitational settlement and thickening to from 25 to 35 per cent moisture, or from 15 to 25 per cent by means of continuous-operation vacuum filters. The residue from decantation or vacuum-filter plants usually carries a fairly high percentage of moisture so that there need be no accumulation of solution, and in most cases there is sufficient balance for a water-wash.

Filter-press dewatering is practiced at the Homestake, Great Fingall, and elsewhere, and illustrates the most exact precision of chemical manipulation. The ore is first amalgamated to reduce coarse-gold content and the subsequent cost of chemical treatment by cyanide. It is thoroughly washed during milling, and lime is added previous to cyaniding to counteract soluble refractories and to assist coagulation. Cyanide treatment is then carried out in the presses on a neutralized slime, and unnecessary exposure to atmospheric influences is avoided, the time of cyanide treatment being limited to a minimum. The result is an extraction and recovery unparalleled in the metallurgy of gold ore and a cyanide consumption well below the average.

With ordinary chamber filter-presses a low percentage of moisture is left in the residue, from 15 to 25 per cent; but where opportunity permits an extensive water-wash it is often advisable to dispense with its use. It has been found that the practice necessitates a much higher cyanide strength than is necessary for the effective solution of the gold; and the loss of cyanide when an appreciable percentage of the moisture in the residue is in the form of barren solution is less than when an attempt is made to retain the whole of the solution, plus the contained double salts, in the circuit. In other words, a reduction in cyanide follows the practice of keeping the zinc content in the solution as low as possible; and the simplest way to insure this is to discharge a small percentage of the solution with the residue as moisture.

With regard to the use of a replacement water-wash with a filter-cake there are few instances where this is practicable. In most cases the time may be better employed in extending the solution-wash. Water will only mechanically displace dissolved gold, but the use of solution may cause residual gold to dissolve as well as replacing gold already in solution. There is also no danger of upsetting the chemical equilibrium of the solution by dilution.

When the residue is being discharged at a high percentage of moisture a final and efficient water-wash is, of course, imperative. Under normal conditions, however, the retention of practically all the solution in a closed circuit, with the constant addition of zinc and other impurities, will eventually result in an increased chemical consumption, and a decrease in actual recovery.

Questions of Acidity and Alkalinity

A great number of ores have an acid reaction. This acidity should be neutralized before the ore is brought into contact with cyanide solution, more especially if the latter contains gold. This neutralization can be effectively carried out by the adoption of milling in water. If milling in cyanide is practiced there is a loss of solvent from this cause alone which is by no means insignificant when circumstances prevent a high alkalinity being maintained in the solution.

On the question of the degree of alkalinity it is common knowledge that, in the great majority of cases, the amount of electrolyte needed for effective settlement involves a higher alkalinity than is good for satisfactory and economincal precipitation. In other cases a very low alkalinity is required for effective solution of the metal in cyanide. When milling and thickening in cyanide solution is practiced it is generally found that the question of alkalinity for solution and precipitation of the gold must be subordinate to the degree required for effective settlement of the ore. Under these conditions, and especially in the case of an ore carrying a variable clay or schistose content, it is almost impossible properly to control the alkalinity to suit metallurgical requirements without interfering with the mechanical capacity of the settling plant. On the other hand when milling in water is practiced a fairly high alkalinity can usually be maintained in the milling circuit with its attendant advantages of improved amalgamation, more effective settlement of the slime, and a clearer overflow for battery-water service. At the same time a thicker discharge can be obtained from the dewaterers. On account of the lower water percentage in the thickened sludge the resultant alkalinity of the pulp, after having been thinned with plant solution, is so low that alkalinity control is then an easy matter, and can be adjusted to a nicety to suit metallurgical and chemical requirements.

These remarks with reference to latent acidity in the ore also apply to the numerous instances where the ore contains reducing agents, raw or partly oxidized pyrites, or other compounds whose detrimental effects on a cyanide salt, or on a solution of metals of uncertain stability, would be wholly or partly neutralized by the preliminary treatment with lime or other alkali. In the case where the available water is acid or naturally impure, the cost of preliminary treatment may often be avoided by milling in lime-water; and a number of the troubles encountered from such a source may be overcome by the addition of sufficient alkali in the battery.

Disadvantage of Large Volume of Metal-Bearing Solution

A further disadvantage of milling in cyanide lies in the fact that the necessary quantity of metal-bearing solution must be very largely increased, and accurate control rendered more difficult. The metal in the battery solution can only be reduced by an increase in the tonnage precipitated, involving further consumption of cyanide and zinc. If the practice of milling an acid ore in a cyanide solution carrying an appreciable quantity of metal is to be avoided, then all the solution coming from the mill should be precipitated. When sliming follows milling it is often difficult, if not unwise, to keep the dilution below 1:10; and the latter figure multiplied by the tonnage would possibly underestimate the amount which ought to be precipitated. In general practice, however, a compromise is usually effected. A part of the solution is precipitated, and the possible ill-effects of bringing the remainder of the dissolved metal in contact with raw ore is not taken into account. The result is in favor of premature precipitation, colloidal absorption of dissolved gold, and a decrease in the net recovery in the plant.

The loss of cyanide due to the necessity of bringing moisture in the crushed ore up to general average cyanide strength has been estimated on the Rand to amount to 0.12 lb. (KCN) per ton of ore. But as the total cyanide consumption on this field, where milling in water is almost entirely practiced, amounts to 0.3 lb. per ton, it is obvious that there are economical advantages in favor of milling in water which greatly outweigh the loss of cyanide from the above cause.

The restricted limit to cyanide operations as a result of milling in water is doubtless responsible for the very low average cyanide consumption; and recent experiments have shown that this could be halved by minimizing the contact of cyanide solution with the air, i. e., by closing-in the plant.

Chemical and Mechanical Loss of Cyanide

In milling-in-cyanide practice the exposure of large tonnages of solution to deleterious atmospheric effects, accompanied as it is in many cases by violent agitation in milling apparatus, is also responsible for considerable chemical loss of cyanide due to the evolution of hydrocyanic acid—a gas whose presence is not difficult to detect in many plants.

As regards chemical loss of cyanide J. W. Hutchison[1] stated that, with reference to Goldfield Consolidated results, a marked increase was indicated by adopting milling in cyanide, the conclusion being confirmed by a three-weeks' test. W. P. Lass also stated,[2] in connection with the preliminary work with Alaska Treadwell ore, that previous agitation with alkali saved 25 per cent of the cyanide consumption. E. M. Hamilton has shown that,[3] in treating a concentrated pyritic material, direct cyanidation caused a loss of 100 lb. of

[1] Eng & Min Jo... V... p. 17...
[2] Min. & Sci. Pre... ...1911
[3] Eng & Min. Jour. V... p. 84...

the solvent per ton, an amount subsequently halved by preliminary treatment with lime-water.

Mechanical loss of cyanide when milling-in-water is practiced is largely influenced by the effectiveness of the dewatering equipment. On the other hand an almost complete displacement of the cyanide solution from the residue may result in fouling, which necessitates a higher cyanide strength in the solution and a greater cyanide consumption than would otherwise occur.

As a matter of fact some misconception exists with regard to this question. Complete displacement of solution by water in a final wash is seldom or never practiced, and in the great majority of instances is impossible to obtain. The amount of solution ultimately discharged with the residue is, more or less, in inverse ratio to the time spent in water washing, as compared with the time spent in solution washing. In other words if it takes an hour to displace rich solution in a thick cake with barren solution, it will also take an hour to displace the barren solution with water. A five or ten-minute water-wash generally suffices, so that the operator of a leaf vacuum-filter is probably discharging more solution with his residue after a water-wash than a filter-press operator would discharge after solution washing only. If it is admitted that a certain percentage of solution is invariably discharged with the residue, which I think is incontestable, then it is obvious why fouling of solution is more in evidence where milling in cyanide is practiced. With milling in water the solution is more easily controlled and the "barren," with the highest zinc content, is used almost in its entirety for washing after filtration. Hence the largest amount of zinc is sent to the dump in the smallest amount of solution. Where milling in cyanide is practiced a very large proportion of the "barren," containing the highest zinc content, is sent back to the main circuit and distributed over a large bulk of diluent.

The statements which are made as regards loss of cyanide as a result of milling in water are not borne out in practice and the majority of operators whose experience has included both methods with a variety of ores will probably agree that the advantages of a preliminary alkaline treatment by milling in water, the close control of the solution on account of the restricted amount, and the low tonnage to be precipitated, are all favorable factors insuring low cyanide consumption in the treatment of a gold ore.

Milling in Cyanide Increases Time of Treatment

As regards time of treatment both Mr. Hutchison and Mr. Lass, already quoted, make decisive statements that, in dealing with their respective ores, a longer time was required to effect solution when milling in cyanide was practiced. These results are coincident with my own, and a number of tests convinced me that the gold in mill solution, when brought into contact with fresh ore in a milling plant, was not of so stable a nature as is generally supposed. The tests indicated a great difference when the ore was cyanided after a preliminary alkaline treatment as compared to a similar handling of the residue from the milling-in-cyanide plant after complete treatment. In the latter case further solution from a comparatively high residue only occurred after protracted periods of agitation and then only in minute amounts, the rate of extraction being practically unaffected by replacement of solution. On the other hand when the orginal ore was agitated direct after a preliminary alkaline treatment a lower residue was obtained in a very much shorter time.

As facilities for mechanical contact between ore and solvent are far more favorable when cyaniding is commenced in the mill it is probable that this apparent delay in the dissolution of the gold is really due to the fact that absorption, adsorption, and possibly re-precipitation of the metal accompanied its solution by cyanide. It may be assumed that the final "extraction" point is delayed until the re-precipitated or absorbed gold has been re-dissolved; and also until as much as possible of the absorbed metal-bearing solution has been osmotically removed by continued contact with a solution of different strength. These final phases would be slow-acting processes and the theory may account for the apparent delay in the extraction of gold from ore after it has been milled in a cyanide solution containing gold.

Effect on Gold Recovery

With regard to the question of gold recovery percentage by both methods Mr. Hutchinson stated that, at Goldfield, crushing in alkaline water followed by cyanide treatment resulted in an increase of two per cent in the extraction, as against milling in cyanide. On the other hand, and dealing with the case of an amalgamable gold ore, the loss in actual recovery would be proportionate to the amount of gold which could have been extracted by amalgamation.

The Alaska Treadwell tests showed equal extractions with straight cyanidation as compared with cyanidation preceded by amalgamation; from which it may be deduced that practical methods would favor the inclusion of the latter process if net recovery only was taken into consideration. The final conclusion, however, is generally dependent on a number of other factors which might deflect the decision in favor of milling in cyanide.

Further complications arise in the matter of the clarification of the solutions where milling in cyanide is practiced. Clarification may often be effected with a sand filter after milling in water. The finely divided colloid which is in so many instances a feature of the solution after milling in cyanide may be coagulated by using excess of lime. Under such conditions the degree of alkalinity which it is necessary to maintain in the solution has a prejudicial effect on precipitation.

Efficient Sampling Favors Milling in Water

In the matter of sampling any decision will be overwhelmingly in favor of milling in water, since the efficiency of the operation is proportionate to the fineness to which the ore has been ground before the sample is taken. This is borne out in assay practice, the assay charge from a sample being the logical equivalent of a sample from a day's run.

There are, of course, mills where an elaborate system of sampling is installed, and where a large proportion of the tonnage is handled and re-ground in the sampling plant. Under such conditions and even with an ore carrying a coarse or variable metal content a good average sample may be obtained, but its representative value is not comparable with a sample of the whole

product that is taken automatically after milling in water. The necessity for the efficient sampling of the ore in a mill cannot be overestimated, and a deal of unnecessary worry and not a little disappointment would be avoided if more attention could be paid to this detail in the first instance. Nothing is more detrimental to the efficiency of operations than the knowledge that no sure conclusions can be arrived at as to the results of the work being carried on, or any reliable forecast made from the assay results of samples of the ore.

Influence of the Personal Factor

Modern milling practice requires constant attention to details, such as the testing of the pulp at every stage of the reduction process. One deterrent factor in cyanide mills is seen in the trouble caused to operators by the poisonous effects of the solution in circuit. I have encountered three classes of millmen. One of these was immune, and obviously so, from any ill-effects. The second class protested an immunity but took particular care, I noticed, to avoid exposure whenever possible. The third class made no pretence and maintained that unless they took special precautions and often avoided a necessary duty they suffered in no light degree. It is impossible to keep one's hands dry in a wet-milling plant although subsequent cyaniding operations may be efficiently controlled by methods involving the minimum of personal discomfort to the operator, and often with an entire avoidance of contact with solution.

In deciding on a process by a comparison of figures the personal factor is often overlooked; and, unless the millmen selected happen to be in the enviable minority and immune from infection, a serious factor against efficient working is encountered by the adoption of milling in cyanide. Infection may result in symptoms varying from slight rash annoyance to perpetual irritation by day and insomnia by night; and the superintendent must often withhold censure for neglect of duty when he knows that vigilance on the part of the millman would have resulted in increased personal discomfort.

The outstanding features of milling in cyanide may be summarized as follows:

Advantages

(1) The milling and regrinding plant offers exceptional advantages for the solution of gold and silver by reason of the intimate contact between metal and solvent.

(2) A saving in water consumption may be effected by milling in cyanide in cases where the settlement of the ore is difficult; where the dewatering units are ineffective; or where the residue is being discharged at under 20 per cent moisture.

(3) A simplification of plant arrangement is possible and separate return-pumping and storage systems for solution and water are unnecessary.

Disadvantages

(1) Decrease in amalgamation efficiency where this recovery method is practiced; corrosion of plates; and increased consumption of mercury.

(2) Higher cyanide consumption and longer time required to effect a lower extraction of the metal in the ore.

(3) Increase in the amount of metal-bearing solution in circuit, with greater liability for mechanical loss; and proportionately higher precipitation costs per ton milled.

(4) Liability of neglect in milling and grinding plant operation on account of the poisonous nature of the diluent.

Applicability

(1) When no advantage, either economical, metallurgical, or chemical, arises from the use of a preliminary alkaline treatment of the ore or the water used for milling purposes.

(2) When amalgamation, if adopted, would result in an inappreciable saving.

(3) When it is not necessary to fine-grind or slime the ore preparatory to cyanidation, thus obtaining a product which, in residue form, usually contains more moisture than if coarser crushing, followed by leaching, had been adopted.

(4) When dewatering prior to cyaniding, to within a few percentages of the amount of moisture to be discharged in the residue, is impracticable.

Probably no other phase of any chemical-metallurgical process is being operated under so many different conditions as the one dealt with in this article; and for this reason an effort has been made to avoid dogmatic decisions. The conclusions are based on many data and observations of practical operations under an immense variety of conditions with an extensive amount of experimental research, coupled with the available information on the subject.

The necessity for the marshalling of facts and the classification of ideas on this important development is obvious. The subject of milling in cyanide has been barely mentioned even in recent text-books; and the method has often been adopted as a necessary concomitant in the utilization of a specialized process of solution recovery, and sometimes without an apparent realization of the advantages in favor of the alternative method of milling and thickening in alkaline water as a preliminary to cyanide treatment.

New York, N. Y.

Technical Association of the Pulp and Paper Industry Meets at Dayton, Ohio

The annual Spring meeting of the Technical Association of the Pulp and Paper Industry will be held in Dayton, Ohio, May 16 and 17, 1918. The particular subject for discussion at the technical sessions is Fuel Economy and Scientific Boiler Room Methods. This subject is of particular importance in connection with the operation of paper mills and it is expected that much information will be brought out for the benefit of the industry. The paper manufacturers of the Miami Valley have arranged for the entertainment of the Association and for the inspection of several of the important paper mills. The meeting is considered important on account of the probable shortage of fuel for paper mills next winter and the necessity of curtailing operations.

Proposed Iron and Steel Works for Queensland, Australia.—The British Board of Trade Journal says that a Royal Commission appointed in 1917 reports that a great deal of research work must be done, and much more information be collected before they can make recommendations with regard to the establishment of a complete iron and steel works. They say, however, that all the essentials are in Queensland for the successful manufacture of pig iron, and that an experimental plant for its manufacture can and should be established (costing roughly $25,000) to test in bulk the available iron ore deposits and to determine the proper site for an eventual iron and steel works. They also believe that the making of pig iron would be a profitable undertaking for the state.

Washing in Filter Presses

By D. R. Sperry

Simple Washing, Recessed Type, Separate Inlet and Outlet For Wash

There are certain cases in which it is desirable to have the wash-water connection on the filter-press separate and distinct from that of the feed connections. This can be accomplished in the recessed type only with the use of frames. It would be possible of course to put in a duplicate feed-channel composed of a separate set of grommets but such an arrangement is rather too expensive and impractical to be employed. When frames are used a channel is formed by placing an eye in the upper corner opposite the one occupied by the grommet. In Fig. 1 a recessed plate-and-frame filter-press having separate inlet and outlet connections for simple washing is shown in two cross-sections.

The upper cross-section shows that the material to be filtered when introduced into the feed-inlet traverses the entire length of the filter-press passing from frame

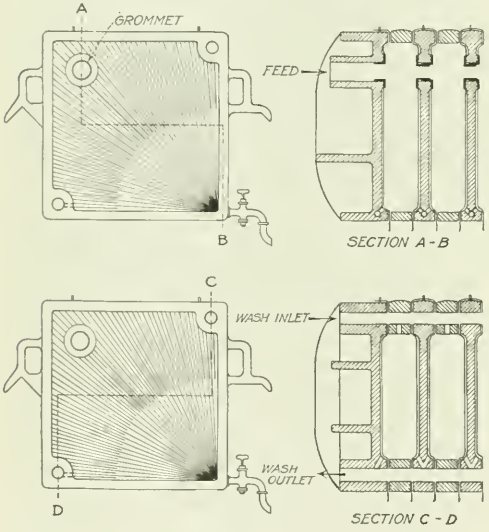


FIG. 1.

to frame by way of the openings through the grommets. The chambers bounded by the frames and filter-base, usually canvas, are thus filled with the material to be filtered, the liquid passing through the filter-base and deposited solids on to the surface of the plate and out of the filter-press via the cocks. The solids are allowed to deposit only until there is still an opening between the solids on either chamber wall. The feed is then shut off and the cocks closed. Wash-water is then admitted into the separate wash-water channel.

The lower cross-section taken through the wash-water inlet and outlet channels shows that the wash-water runs the entire length of the filter-press dropping into each frame by means of the port in the eye of each frame. The wash-water thus brought into intimate contact with the deposited solids, passes through them, against the plate surface and out, not through the cocks as the filtrate did, but through the port in the opposite corner. The ports feed into the wash-water outlet formed by the eyes in the lower corner. The issuing wash-water is thus led to the outside of the filter-press at the point called the wash-water outlet. The frame used in this arrangement is shown in Fig. 2. A photograph of a plate belonging to this system is shown in Fig. 3. For the filtering and washing of certain materials this arrangement is a very convenient one. The

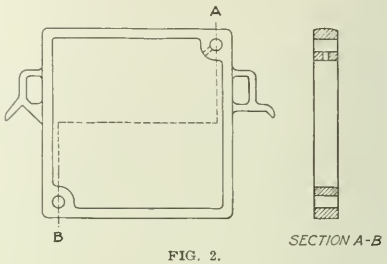

FIG. 2.

feed-channel formed by the openings in the grommets makes a very generous feed opening suited to heavy materials. The fact that the wash-water has its own entrance and exit permits the use of permanent connections and allows the washing to be carried on independent of the filtering process.

Simple Washing, Flush Plate, Separate Inlet for Wash

In the flush type of plate without grommet feed, simple washing may be carried on having a separate inlet for the wash-water. Such an arrangement is shown in cross-section in Fig. 4. The frame alone is shown in Fig. 5. The upper cross-section indicates that the feed-inlet channel formed by the eye in the corner diagonally opposite the cock, leads the material to be filtered directly to the interior of each frame. Here as in the preceding

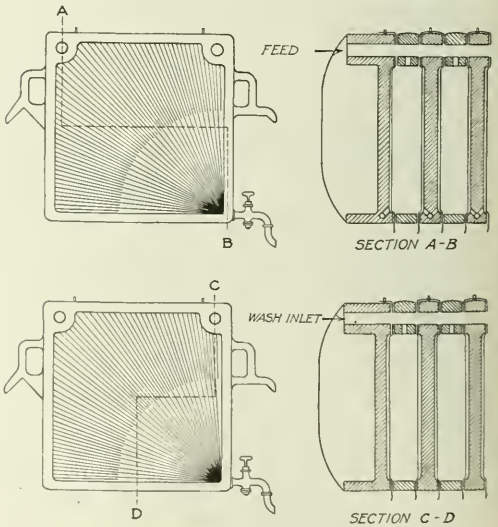

FIG. 4.

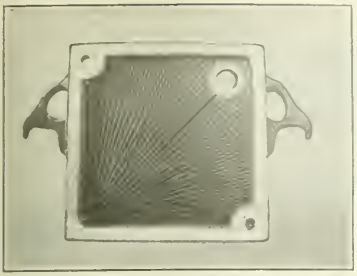

FIG. 3.

FIG. 11.

case the solids are allowed to build up on the sides of the chamber, usually cloth, only until the two walls of solids still leave an open space between them. The feed is then shut off and wash-water admitted into the wash-water channel.

The lower cross-section shows that the wash-water is conveyed to the open spaces left in the chambers by means of the channel formed by the eye opposite the feed eye. The wash-water passes through the solids against the surface of the plate and out by way of the cocks, precisely as the filtrate did. A view in a filter-press having this arrangement is shown in Fig. 6. The filter-press is opened to show the eyes and is not clothed. In Fig. 7, a photograph of a filter-press showing the head connections as they appear in this arrangement is shown. This type of filter-press is used where the material to be filtered does not bear solids which have a tendency to clog up small openings. The hole connecting the feed-channel with the interior of the frame is ordinarily quite small, hence, it is unwise to use a filter-press of this kind upon heavy materials. An exception to this rule is the case in which the frames are of such thickness that a fair sized port running to the feed-channel is practical.

Simple Washing, Flush Plate, Separate Inlet and Outlet for Wash

In practice it is often inconvenient to have the wash-water follow the same path as that taken by the filtrate. It is sometimes very necessary to allow no liquid other than the filtrate to come in contact with the cocks or gutter. In such a case a separate outlet for the wash-water must be provided. This can easily be done and arrangement for this purpose is shown in cross-section in Fig. 8. As in the case just given, the upper cross-section shows that the material to be filtered reaches the interior of each frame by means of the channel formed in the upper left-hand corner. When the cake on each side has been deposited only enough to have an open space down the center of the chamber, the feed is shut off and the cocks on each plate and head closed. Wash-water is then admitted into the wash-water channel, shown in cross-section in the lower part of Fig. 8. It can be seen that the wash-water reaches the open spaces left in the centers of the chambers by means of the wash-water port in the corner of the frame.

A separate frame in cross-section is shown in Fig. 9. The wash-water passes through the solids and emerges against the surfaces of the plates. It cannot leave the plate via the cocks, which are closed, as did the filtrate, but it does leave the plate by means of the port in the opposite corner which leads it into the wash-water outlet channel formed by the eyes in the lower left-hand corner. In this manner the wash-water both enters and leaves the filter-press without coming into contact with the cocks or gutter. The connections can be made permanent and the wash-water led to any desired place. In Fig. 10 is shown a photograph of a filter-press arranged as last described. Fig. 11 shows a picture of a separate plate used in this arrangement.

Closed Discharge for Filtrate

In any of the foregoing cases the filtrate may be caused to issue from a single connection in the fixed head, thus dispensing with cocks on each plate and head. This is called "closed discharge." In such a case there is placed an eye in the corner where a cock would otherwise be placed. This forms a channel the entire length of the filter-press. The drainage from the plates runs into the channel through ports running from the eye to both surfaces of the plate. This is often used where it is undesirable to allow the filtrate to come in contact with the atmosphere, or where it is desirable to elevate the filtrate to a level higher than that of the filter-press.

Simple Washing in General

In actual practice one does not find many filter-presses using simple washing. There are several objections to it and in the majority of cases the other kind of washing, known as thorough washing, to be described later, is preferable. In the first place it is an exceedingly diffi-

FIG. 6.

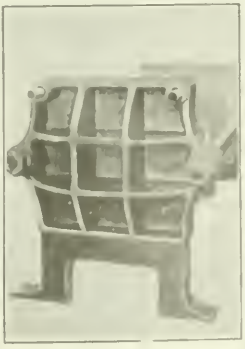

FIG. 7.

FIG. 10.

cult matter when handling the usual mixtures of solids and liquids to stop the filling operation at that point in which the adjacent cake walls are not yet touching each other. If all the conditions were precisely the same during each fill this system would be much more in use today than it actually is. The time allowed for filling is no criterion unless the conditions are always the same. It is very seldom that the per cent of solids and their other physical properties are the same each fill. If they vary, then the filling time varies and the cake walls will either touch each other, causing poor washing, or they will be unnecessarily far apart decreasing the capacity of the filter-press. The pressure under which filtration is carried on is seldom exactly the same, due to different pump speeds, different operators, etc., making still another factor likely to cause trouble. The temperature will vary to a certain extent reducing the viscosity and changing the rate of deposition, making a third variable.

In order to secure the same capacity for solids as in the case of thorough washing where the chambers are allowed to fill completely, it is necessary that the chambers be made thicker or that the capacity for solids be decreased. It is a matter of common observation and of fact, that the cake on the walls of the filter-press chambers forms thicker at the bottom than at the top. This is due to the effect of gravity on the solids which are being deposited. This means that if the wash-water is to reach all parts of the cake, it is necessary to stop the filling operation while the thicker bottom portions are still apart requiring a frame or chamber thicker than would be the case were the cake uniform in thickness. If this is done it can readily be seen that the upper or thinner part of the cake wall will be more thoroughly washed than the lower and thicker portion.

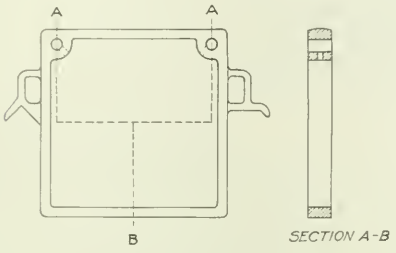

FIG. 5.

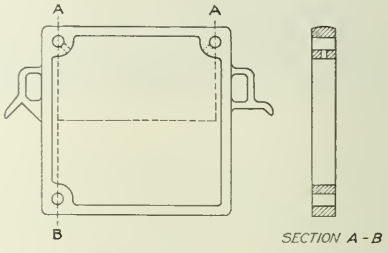

FIG. 9.

Simple washing is used most effectively in the case of finely divided substances which in a reasonable filling time form a very thin cake. In such a case, thorough washing is almost out of the question if the chambers are of much thickness, while by the use of simple washing all parts of the cake are very thoroughly washed. In finely divided substances the effect of gravity tending to make the cake walls of variable thickness is small, which is a point in favor of simple washing for this class of mixtures.

Batavia, Ill.

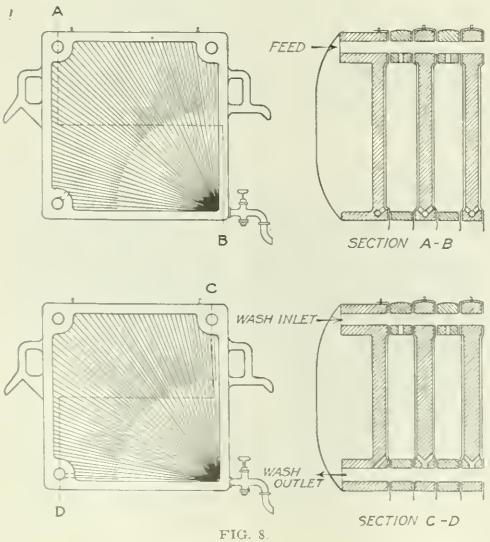

FIG. 8.

Potash Exploration.—Secretary of the Interior Lane has approved working instructions and regulations under the potash leasing act of Oct. 2, 1917, a matter which has been given the most careful consideration, in view of the importance attached to this pioneer work in the development of a great national asset. The act is liberal in its terms, authorizing the exploration for and disposition of potash deposits generally in the public lands of the United States, undea system that provides for a preliminary permit to the holder for the exclusive privilege of searching for deposits of potash for a period of not exceeding two years. The acreage embraced within one permit is limited to $2560 acres, and the Secretary, upon a satisfactory showing that valuable deposits of potash have been found within the permit, is authorized to issue a patent to not exceed one-fourth of the amount covered by the permit, the remaining lands in the permit being subject to lease either by the permittee or others, after advertisement, competitive bidding, or such other methods as the Secretary may by general regulations adopt. To the end, therefore, that the liberal purposes of the act may find the fullest scope of operation, the instructions and regulations now approved, are broad in outline, simple in form, yet so directly addressed to the matter in hand that it is believed all applicants under the law will find but little difficulty in presenting their claims for consideration by the Department. Requests for copies of these instructions should be addressed to the Commissioner of the General Land Office, Washington, D. C.

Annealing and Recrystallization of Cold-Rolled Aluminium Sheet

By ROBERT J. ANDERSON

THE present article gives the results of a series of tests made on the effects of heat at different temperatures on the softening of cold-rolled sheet aluminium; similar results, other than the late paper by Carpenter and Taverner,[1] so far as is known, have not hitherto appeared in the technical press. The common practice employed for annealing cold-rolled sheet aluminium is to heat the metal for a long period of time, say 18 to 30 hours at a temperature of approximately 375 deg. C. The annealing is carried out in large furnaces of the gas or oil-fired types, under pyrometric control, and upon completion of the anneal the metal is withdrawn and allowed to cool in air. Cold-rolled aluminium so heat-treated is very soft and pliable—the Shore scleroscope hardness being about 4 to 5. The aluminium referred to is first-grade metal analyzing 99 per cent Al and over, and with the impurities Si, Fe, Mn, and Cu in subordinate amounts. Experiments (not described in this article) have been made by the writer which showed that hard-worked, i.e., cold-rolled, aluminium can be softened to 4 or 5 Shore scleroscope hardness-number by short time exposures at temperatures near 375 deg. C. A description of the tests carried out on a variety of gages of cold-rolled aluminium sheet follows.

A chill-cast aluminium ingot was heated to 455 deg. C. in an ingot-heating furnace, and remained in the furnace approximately six hours before rolling. The analysis of this metal was as follows:

	Per Cent.
Cu	0.25
Fe	0.45
Mn	trace
Si	0.35
Al (by diff.)	98.95

The ingot was broken down hot in a two-high breakdown mill to a slab whose dimensions were, 0.2291 in. x 40 in. x random; the reduction of the ingot, whose approximate dimensions were, 4 in. x 12 in. x 17 in., to the slab of the size given was accomplished by five or six passes in the mill. The slab so made was allowed to cool to room temperature; it was then slabbed cold to 0.1215-inch thick, and was then rolled to a succession of gages as follows: 10, 12, 14, 16, 18, 20, 22, 24, 26 and 28. The separate gages were all obtained from the same slab by rolling the slab to 10 gage, then shearing off a section, then rolling the remainder to 12 gage, shearing off a section, and so on until the range of gages mentioned was obtained. Sufficient metal of each gage was obtained to furnish samples for the annealing tests. In annealing, the time and temperature were varied over a wide range, as is shown in the accompanying tables, but the aim in general was to produce a softening to 4 or 5 Shore scleroscope number—this being considered maximum softness from the standpoint of practical mill operation. Annealed aluminium, however, at times may give a lower scleroscope reading.

[1]Carpenter, H. C. H. and Taverner, I. The Effect of Heating at Various Temperatures on the Rate of Softening of Cold-Rolled Aluminium Sheet; Paper before the Inst. of Metals (London), Fall, 1917; and in Engrg. (London), vol. 104, 1917, No. S., p. 212.

Relation of Hardness and Ductility

Hard-worked aluminium sheet will have a scleroscope hardness ranging from 13 to 15, and in the hard-worked condition the metal cannot be drawn into shapes in the draw press. In the annealed condition, the scleroscope hardness will be 4 to 5; semi-annealed or "half-hard" sheet aluminium has a scleroscope hardness of from 7 to 11, depending upon the annealing period or the number of passes through the rolls. Thus a "half-hard" sheet may be produced by a partial anneal upon a cold-rolled sheet, or by giving an annealed sheet a few passes through the rolls of a finishing mill. An annealed sheet whose scleroscope hardness is 4 to 5 may possess maximum ductility or very little depending upon the period of annealing and the temperature. For instance, if a given cold-rolled sheet be annealed for say 30 hours at 400 deg. C., its scleroscope hardness will be about 4, but it will be in a weakened condition and possess a relatively large grain size; on the other hand, if the same metal be annealed for 10 minutes at 400 deg. C., its scleroscope hardness will also be about 4, but it will be much stronger and have a smaller grain size than the first-mentioned sheet. For drawing, bending, and shaping operations on aluminium sheet, it is necessary that the metal have the maximum ductility which can occur together with a scleroscope hardness of 4 to 5.

Annealing Experiments On Aluminium Sheet

In Table I, are given the results of tests made on the original hard sheets as they came from the mill. The ductility values were obtained with the Erichsen ductility testing machine for sheet metal, and hardness was taken with the Shore scleroscope. Percentages of reduction on the various gages of sheets were calculated according to formula, using 40 inches as the constant width, and starting from the 3-gage slab. Table II gives the percentages of reduction as calculated from the formula.

$$\frac{\text{Original area} - \text{final area}}{\text{original area}} \times 100 = \text{per cent reduction}$$

Annealings were made on all the different gages mentioned above, employing different times and temperatures, for the purpose of fixing the softening range of the metal for a given amount of deformation, i.e., percentage of reduction. Scleroscope hardness numbers were used to indicate softenings, and Erichsen tests were made when desirable. The results are given in Tables IV to XIV inclusive. There was a measurable

TABLE I. ERICHSEN AND SCLEROSCOPE VALUES FOR THE HARD SHEETS

Mark	Sheet Gage	Scleroscope Hardness	Thickness in Millimeters	Indentation in Millimeters	Measured Thickness in In. by Micrometer
1	3	5 0	5 96	. . .	0 2291
2	8	12 5	3 11	. . .	0 1215
3	10	14 0	2 58	10 01	0 1037
4	12	15 0	2 05	9 49	0 0841
5	14	15 0	1 70	8 24	0 0650
6	16	15 5	1 32	7 28	0 0512
7	18	15 0	1 02	6 58	0 0401
8	20	15 0	0 79	6 16	0 0321
9	22	15 0	0 68	5 92	0 0275
10	24	14 5	0 54	5 16	0 0220
11	26	15 0	0 40	4 57	0 0169
12	28	13 5	0 30	3 64	0 0128

NOTE.—The figures given represent the mean of closely agreeing determinations.

TABLE II. PERCENTAGES OF REDUCTION OF HARD SHEETS

Mark	Sheet Gage	Measured Thickness in In.	Percentage Reduction
1	3	0.2291	. . .
2	8	0.1215	47.00
3	10	0.1037	54.85
4	12	0.0841	63.30
5	14	0.0650	71.60
6	16	0.0512	77.70
7	18	0.0401	82.60
8	20	0.0321	86.00
9	22	0.0275	88.00
10	24	0.0220	90.50
11	26	0.0169	92 70
12	28	0.0128	94.50

NOTE.—There is some difference in the measured thickness of the sheets in inches compared to the measured thickness in millimeters (from the Erichsen tests) calculated to inches due to variation in the thicknesses of the sheets and the fact that the measurements were made at different points on the sheets, but these differences do not vitiate the results.

TABLE III. SHOWING VARIATIONS IN THICKNESSES OF SHEETS

variation in the thickness of the sheets at different points on their surfaces; and the measured thickness in inches by micrometer, the measured thicknesses in millimetres from the Erichsen test, the calculated inches to millimetres, and the calculated millimetres to inches are summarized in Table III. The annealings were carried out in a small laboratory electric furnace of the resistance type, and the temperatures given are accurate to ± 5 deg. C. The samples were cut from the various gages to a size of 3 in. x 10 in., thereby providing sufficient surface for three Erichsen tests and scleroscope hardness tests.

Appearance of the Annealed Samples

Blisters began to be apparent on samples marked F, which were annealed for 60 minutes at 350 deg. C.; sheets marked G, annealed for 10 minutes at 400 deg. C. showed small blisters in all gages, as did those

marked H, I, J and N. The matter of blistering is somewhat uncertain, and the writer has obtained such contradictory results on aluminium that he would not care to speak with certainty at the present writing. The results of the tests under discussion show that the metal blistered in all gages when heated to 400 deg. C. for even short times, and that at 350 deg. C. blistering starts after annealing for 60 minutes. Blisters are more or less dependent upon the original cast metal—the gas contained being a function of the temperature and speed of pouring, and also probably upon the melting practice. Thus, it has been found that certain sheets blister while others do not when annealed at the same temperature and for the same length of time.

Other Annealing Experiments

A set of samples of all gages were annealed in a large mill furnace at 370 deg. C. for 24 hours, and the results of the tests are summarized in Table XIV. All the fractured domes of the Erichsen tests were extremely coarse, indicative of large grain size and poor drawing quality. Long-time annealings for cold-rolled aluminium sheet are very harmful and confer undesirable properties upon the metal. A number of re-annealings were made upon 18-gage cold-rolled sheet, and the results of the physical tests were comparable to those in Table VIII.

Curve Plots

In the case of cold-rolled aluminium sheet of a given gage, it is possible to make curve plots showing the time required for softening the metal to 4-5 Shore scleroscope number when employing various temperatures. The time for a given temperature depends upon the percentage of reduction of the cold-rolled sheet, and to a less extent upon its thickness. Fig. 1 is a thickness-indentation curve for cold-rolled aluminium sheet; indentation, as will be noted, varies with the thickness of the metal—heavier gages of sheets giving deeper indentations, other things being equal. Fig. 2 is a curve plotted from a set of composite results from the various tables (the figures were taken so that the Shore scleroscope number was 5 or below, and the

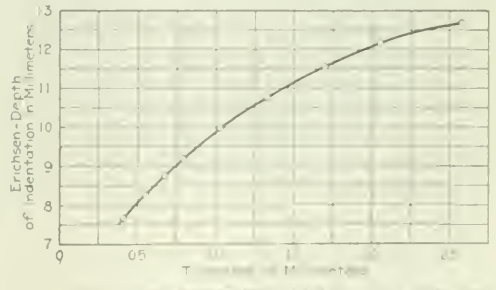

FIG. 2 THICKNESS—INDENTATION CURVE FOR ANNEALED ALUMINIUM SHEET

depth of indentation the highest for the shortest times and lowest temperatures, together with a smooth dome on the ruptured Erichsen test piece). The figures used were those in Table XV, and the curve shown in Fig. 2 may be taken as a correct thickness-indentation curve for annealed aluminium sheets for drawing purposes.

Microscopic Examination

Microsections were procured from most of the annealed samples, and the internal structure of the metal was examined for general characteristics, recrystallization, etc. The photomicrographs in Figs. 3 to 6 inclusive illustrate the effects of annealing 12-gage cold-rolled sheet which had been reduced 63.30 per cent in the cold. Fig. 3 is a photomicrograph of the original cold-rolled sheet; there is no evidence of crystallinity; grain boundaries cannot be discerned, and the metal is evidently mostly amorphous. The degree of deformation employed was large, and the structure of the metal is as would be expected. Fig. 4 illustrates the appearance of this metal after annealing for 60 minutes at 350 deg. C.; recrystallization has commenced but is far from complete. However, when annealed in the manner just mentioned, the metal was "dead" soft, even though recrystallization had not proceded very far. Fig. 5 shows the same metal after annealing at 400 deg. C. for 60 minutes, and recrystallization is still far from complete. Fig. 6 is the same metal after annealing at 600 deg. C. for 10 minutes: it will be observed from inspection of the photomicrographs that with a much shorter time but at a more elevated temperature that recrystallization has proceded further in Fig. 6 than

7E	18	82 60	Recrystallization commenced

NOTE.—Samples marked E were all annealed for 30 minutes at 350 deg. Cent.

in Figs. 4 and 5. Recrystallization is still incomplete in Fig. 6. These photomicrographs show, and microscopic examination has confirmed the fact, that cold-rolled aluminium sheet recrystallizes but slowly on annealing. Microscopic examination of other gages gave results in conformity with what was expected, and in general recrystallization commences at lower temperatures and with shorter times with increasing deformation. This may be instanced by the summary of the microscopy of annealed sheets of various gages in Table XVI.

As to the mechanical softening of cold-rolled aluminium sheet from 15 to 4 scleroscope-number without concomitant recrystallization: In the present somewhat uncertain state of our knowledge, it appears that there may be a complete mechanical softening, which occurs and leaves the strained structure of the metal the same so far as the microscopic examination is able to show. With prolonged annealing, this may be followed by recrystallization and grain growth, while the softness remains the same or nearly so. The mechanical softening brought about by heating strained metal, such as cold-rolled aluminium sheet, is probably due to an undescribed change in the amorphous metal enclosing the remaining grain fragments resulting from extreme deformation in the cold, or to a continued absorption of the amorphous metal by these fragments, or possibly both. These changes in the condition of the amorphous metal are not sufficient to bring about visible changes in the etching characteristics of the internal structure.

Summary

The results of the tests made on the annealing of cold-rolled aluminium sheet show, and their practical application in the mill has proved, that there is no necessity for the present general practice of annealing aluminium. The effect of long-time annealings, such as are common in present practice, where sheets are exposed for say 24 hours at 375 deg. C., is to cause an undue coarsening and weakening of the metal which is evidenced by the coarse domes in the Erichsen test. In Table XIV, it will be noticed that all the samples gave very coarse domes. Fabricating blanks so annealed and which have undergone deep draws in the draw press also show the same coarse appearance at the edges of the drawn shapes, and this can be traced only to the long annealing period. The Erichsen apparatus in furnishing data as to the ductility of metal sheets, and their workability in the draw press provides a means of testing which is valuable.

Assistant Chemist in Forest Products (Male).—The United States Civil Service Commission announces an open competitive examination for assistant chemist in forest products, for men only. Vacancies in the Forest Service at Madison, Wis., at entrance salaries ranging from $1200 to $1800 a year, depending upon the qualifications of the appointee, and in positions requiring similar qualifications, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The duties of appointees will consist of the investigation of such problems as the processes for the preservation of wood against decay, the wood distillation industry, and the practical problems of the pulp and paper industry.

Competitors will not be required to report for examination at any place, but will be rated on the following subjects, which will have the relative weights indicated, on a scale of 100: (1) physical ability, 10; (2) education and experience, 90.

The Forest Products Laboratory deals with economic and technical problems concerning the utilization of the products of the forests of the United States. The technical force of the laboratory consits chiefly of men who have had an engineering or a chemical training. The present staff consists of about 80 men receiving salaries ranging from $900 to $3500. Besides the laboratory at Madison, Wis., offices are maintained at Washington, D. C., San Francisco, Ca., and Portland, Ore.- A laboratory for testing the mechanical properties of timber is operated at Seattle, Was.

On account of the urgent needs of the service, applications will be received until further notice. Papers will be rated promptly and certification made as the needs of the service require.

Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D.C.; the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass., New York N. Y., New Orleans, La., Honolulu, Hawaii; Post Office, Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Cal.; Old Custom house, St. Louise, Mo.; Administration Building, Baboa Heights, Canal Zone, or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R. Applications should be properly executed, excluding the medical certificate, and filed with the Civil Service Commission, Washington, D. C., without delay.

The Use of Wood in Chemical Apparatus

Classified Results of an Inquiry by the Forest Products Laboratory, Regarding Practical Experience With Wooden Containers Used in Various Chemical and Metallurgical Industries

By A. W. SCHORGER

THE great expansion in the chemical and metallurgical industries during the past three years has resulted in increased interest in the use of wood for apparatus, particularly apparatus for use with acid solutions. In some cases manufacturers have constructed wooden apparatus because they could not obtain metal; but in many cases wood has a distinct advantage over all other materials when used in the presence of acids. The receipt by the Forest Products Laboratory of numerous inquiries about the suitability of various species of woods for use in such apparatus led to an attempt to collect such information as might be available on the subject.

Laboratory experiments, while possessing some value, were considered inadvisable since years would have been required to complete the tests; also it would have been impossible even to approximate certain commercial conditions. Accordingly, a large number of letters were sent out to various manufacturers and users of wooden apparatus asking what their experience had been, especially in regard to the use of wood with acid solutions. The numbered paragraphs of this paper embody a summary of the replies received. No responsibility is assumed for their accuracy.

It is interesting to note the geographical influence upon the replies, preference generally being given to a wood growing in the region in which it was used. In the North, Central and New England States white pine and Norway pine were used most; in the West, redwood, and Douglas fir; and in the remaining territory, longleaf pine and cypress.

Effect of Inorganic Acids on Wood

Wood is readily attacked by most of the inorganic acids. A 40 per cent solution of hydrochloric acid and concentrated sulphuric acid dissolves cellulose readily. More dilute acids attack the lignin and have slight action on the cellulose. In fact numerous attempts have been made to manufacture paper pulp by removing the incrusting materials with acids. For this purpose Barne and Blondel[1] used nitric acid; Orioli[2] using 40 per cent of a mixture of 20 per cent HNO_3 and 80 per cent HCl, obtained 50 per cent of long, strong fiber from 100 parts of wood; Lifschütz[3] employed a cold mixture of dilute nitric and sulphuric acids (3:1) and obtained 95 per cent of fiber. The solution was reused until the nitric acid was exhausted, leaving a solution containing H_2SO_4 and saturated with oxalic acid. Highly concentrated mixtures of nitric and sulphuric acid nitrate the wood.[4] Even very dilute solutions of hydrochloric acid or sulphuric acid contained in wood char it when it is dried at a temperature of 100 deg. C. The main action of acids on wood is hydrolytic. The lignin is separated from the cellulose fibers, the wood gradually disintegrating.

Pickling Tanks

1. A Chicago firm using hydrochloric acid and sulphuric acid at room temperature in its galvanizing department preferred Norway pine, but owing to inability to obtain suitable lengths was using yellow pine. The tank, using sulphuric acid of 15 to 16 deg. Bé and steam heated to a temperature of 82 to 99 deg. C., was made from longleaf yellow pine.

2. Wooden vats 15 to 40 feet in circumference are made of common pine, native of Massachusetts (probably white pine). This material requires less attention and shows a longer life than long leaf pine, cypress, or spruce. All of these woods have been thoroughly tried out. Absolutely dry cypress gave a slightly longer life than any of the others, but it was found commercially impractical to obtain thoroughly dry lumber. The sulphuric acid solution varies in strength from 3.5 to 8 per cent and the temperature ranges from 74 to 98 deg. C. The life of the tanks varies from one to two and one-half years, depending upon the size of the tank and the nature of the service, the smaller tanks lasting longest.

3. We use dilute sulphuric and hydrochloric acid at a temperature of about 65 deg. C. in our galvanizing plant. Both white pine and cypress have been used. The tanks fail by wearing off at the top and at the joints. The acid seems to eat away the material that holds the fibers together. Pine tanks last seven years and cypress from eight to nine. They are used only ten hours daily.

4. The hydrochloric acid is used undiluted and the sulphuric acid in about a 2 per cent solution, the former being generally used at a temperature of 21 deg. C. but has been used up to 65 deg. C.; the sulphuric acid is used at 65 deg. C. The tanks for these acids have been made of cypress, white pine, fir or oak, chiefly the first two; and it is our experience that as far as the wood is concerned its chief asset was in its natural advantages as a tank lumber, i. e., for holding water or any liquid, and in its ability to stand hard usage, as thousands of tons of steel are passed through the tanks in the shape of angles, etc. In being lowered and raised in and out of the tanks the steel causes considerable chafing and wear. Tanks which have now been in use six years show no appreciable change in the strength of the fibers $\frac{1}{16}$ to $\frac{1}{8}$-in. beneath the surface and resist the insertion of a knife blade the same as new wood. The breaking away of a splinter from the planks appears to be almost as difficult as with new wood.

5. For ordinary tanks for pickling steel products we always use cypress, which we understand from users of our tanks is very durable so long as the contents are not stronger than a 5 per cent solution.

6. We use hydrochloric and sulphuric acids at a temperature of 70 to 80 deg. C. We have had best success with cypress wood. The life of the tanks in our galvanizing department is about two years. The acid makes the wood spongy, and in about two years' time the solution begins to ooze through the staves so badly that the tank must be abandoned. The wear and tear upon our tanks is rather severe from the fact that we are galvanizing heavy parts and heavy bundles of small parts.

7. We use cypress with the best results for galvanizing tanks.

Storage Tanks for Hydrochloric Acid

1. The hydrochloric acid is stored in a double-walled tank, the inner being made from "Louisiana red gulf *cypress*" and the outer tank of "special heart grade" *longleaf yellow pine*. The space between the tanks is filled with highly refined pitch-tar, which remains in a plastic condition. The inside tanks are sometimes painted with two or three coats of a mixture of rosin and pitch, and before assembling each stave is dipped in a hot tar solution.

2. Our experience—that is to say, the reports of our customers—has been that the best material for muriatic acid is either *longleaf pine* or Washington *fir*.

3. In the manufacture of muriatic acid, storage tanks were made of California *redwood*, and the acid was also shipped in tank cars made of the same wood.

The wood was prepared by first boiling tar until all the volatile products at the boiling point of the tar were distilled off, and then the clear redwood was immersed in this and boiled for about half an hour. The staves were then used to make up the tanks. The muriatic acid was maintained at atmospheric temperature and no heating was carried on in the tanks. To the writer's knowledge tanks made up in this manner lasted twenty years.

4. You can make wooden tanks and coat them with a mixture of asphaltum and some wood tar and they will stand quite a long time. We have some wooden tanks so built that we have been using for quite a number of years for transporting and storing muriatic acid. However, there is no wood that we know of that will stand for any length of time, either treated or not, the effects of either nitric or sulphuric acids.

5. We are manufacturers of sulphuric, muriatic, and hydrofluoric acids; the most serious trouble encountered is that of concentrating our acids to the commercial specific gravity. The fumes from the latter acids are weak, warm and penetrating. The best grade of wood which we have found to answer our purpose is white pine. We have also used some cypress with fairly good success; nevertheless we consider white pine the best for our purpose and for all the acids produced at this plant at various temperatures and gravities.

6. Hydrochloric acid scarcely attacks wood, especially if the latter is soaked in paraffin wax.

Apparatus for Use with Acetic Acid

1. We use a great many wooden tanks in connection with our acetic acid operations. We have used redwood, cedar, and cypress tanks. The cypress are the most satisfactory. We also use wooden pipe lines, and all of these are made from spruce. They are only fairly satisfactory, however.

2. Wooden tanks are used in the manufacture of the vinegar and in its transportation. In both cases fir and cypress are used and with careful treatment they last a great many years. The acid seems to preserve the wood.

3. Acetic acid and vinegar are usually handled in fir tanks.

4. The writer has had experience in the use of wood in the manufacture of acetic acid. Ordinary white pine tanks were used to store the various strengths of acetic acid. Acetic acid was also shipped in second-hand whiskey barrels and we noticed no effect of the acid on the wood.

We also performed concentration and purification of acetic acid in a wooden tower made of clear *white pine*. This tower showed no effects of the acid.

5. We use wooden tanks made of cypress and pine in the manufacture of vinegar, the acetic acid content of which never exceeds 11 per cent.

6. Douglas fir is used almost exclusively by vinegar plants.

7. During the past few years we have had occasion to make smoke condensers for a certain company. The material must resist the action of acetic acid. After a good many years of experience they have settled on Norway pine as the proper material. They have tried Western fir and condemn it absolutely.

8. We have used wooden tanks as containers for pyroligneous acid, and with good results. These tanks are made of pine, and we have some still in good condition that have been in constant use for the last fifteen years.

9. A great many cypress tanks are used in the generation of vinegar and acetic acid and for holding vinegar.

Separators for Storage Batteries

Wood is used extensively for separators in lead storage batteries containing sulphuric acid of from 1.2 to 1.4 specific gravity.

The wood must be given a preliminary treatment; for when it is used in the natural state substances very injurious to the lead plates are formed in presence of the sulphuric acid. Acetic acid is generally considered to be one of the most undesirable substances produced, but according to Skinner[2] a small quantity of acetic acid is beneficial rather than harmful to the negative plates. He finds that "white pine, Douglas fir, and the common species of cedar" are especially desirable for separators. In Skinner's patent, the woods, before use, are steamed under pressure for about 12 hours or boiled at atmospheric pressure for from 21 to 48 hours. The swelling and softening thus produced lower the internal resistance of the separators. In previous patents the separators were first treated with a 25 per cent solution of sodium bisulphite[3] at a temperature of 100 to 175 deg. C.; or with a 15 per cent solution of sodium sulphite[4] at 100 deg. C. for one hour. These solutions remove a portion of the lignin, and their use is founded on well-known methods of manufacturing paper pulp.

Morrison[5] treats the separators with melted paraffin. Heap[6] employs an alcoholic solution of caustic potash,

[1] U. S. Patent 1,130,640 (1915)
[2] Skinner, U. S. Patent 1,[illegible] (1914)
[3] Skinner, U. S. Patent 1,[illegible] (1914)
[4] U. S. Patent 1,068,77[illegible] (1913)
[5] U. S. Patent 1,051,5[illegible] (1913)

in which the separators are treated for four hours at 140 deg. C. and at a pressure of 100 pounds. Marino[10] steams the separators for 15 minutes at 120 deg. C. and then subjects them to oxidation by immersion in a 20 per cent solution of hydrogen peroxide for about 3 hours. The separators are finally steamed again for ten minutes at a temperature of about 110 deg. C. The method of Dodge[11] for preparing the separators for use consists in soaking them successively in dilute sulphuric acid and caustic potash. Whitehead and Marino[12] first submit the wood to an ammoniacal copper solution and then to a bath of ammonia sp. gr. 0.88. The separators are then treated successively with water, nitric acid, and sulphurous acid, and finally with alcohol, caustic potash, and ethyl acetate in various proportions.

Among the woods considered as having special value for storage batteries are yellow pine[13], cypress *(Taxodium distichum)*, and redwood *(Sequoia sempervirens)*[14]. Cypress is also considered to be least affected by alkaline solutions.[14]

Lyndon[15] states that for large size station storage batteries heavy wooden tanks lined with lead are universally used. These should be made of sound oak, pine, or teakwood thoroughly dried and boiled in paraffin or its equivalent, so that the pores may be completely filled. "Resinous wood such as pine has proved to be the most satisfactory and durable." This author also states that basswood is invariably used for the separators. At the present time basswood is being used to only a limited extent, preference being given to cypress, redwood, Douglas fir, and Port Orford cedar.

Tanks for Saponification of Fats

1. Several of our customers using our tanks in the process of recovering glycerine from soap fats specify 4-inch genuine Louisiana red cypress for the bottoms and staves, and extra heavy hooping. This, we understand, is not only due to certain acids used in this process, but also because the fat contents of the tank are boiled.

2. Our experience is practically limited to the use of wooden tanks in contact with a solution of sulphuric acid containing also sulphonic acids, at a concentration of 1 to 2 per cent for each component at a boiling temperature, in the operation of the Twitchell process for fat splitting. We use for this purpose Louisiana cypress.

Tanks in continuous use with the Twitchell process, if properly constructed, have a life of at least ten years. The inner layer becomes charred in appearance and we therefore use staves not less than three inches thick; the charring will not penetrate more than about ¾-inch. We have recently taken down a tank which has been used about fifteen years and find the inside of the staves charred as described above, while the remainder of the wood still remains in serviceable condition. (A portion of a stave sent to this laboratory proved to be dense, resinous longleaf pine.)

Miscellaneous

1. The slight experience that we have had leads us to believe that cypress wood stands the action of all kinds of acids the best.

2. We have had so many complain of Washington fir that we have given up the manufacture of Washington fir tanks for acid of any kind unless specifically ordered. We consider yellow pine in general better than white pine.

3. We make the tanks principally from Louisiana red gulf cypress. In some cases longleaf pine is requested. We have also made some from Oregon fir. It appears that for certain chemicals longleaf pellow pine is specified by the users on account of the acid resisting qualifies of the pitch contained in the pine.

4. Longleaf pine seems to be most popular with the paper mills for sulphite solution, while cypress is universally demanded by the chemical companies.

5. We have tanks constantly in use exposed to dilute acetic, muriatic, sulphuric and chromic acids, and, in our opinion, nitric acid could also be used if sufficiently dilute. These acids are in various dilute solutions, say about 5 to 10 per cent, and above the solution they exist in the form of steam. The temperature rises as high as 100 deg. C.

The best wood to use for these tanks is longleaf yellow pine as it seems to last longer than any other kind. Many of the dye-stuff and chemical manufacturers use wooden tanks generally, and a good many use acids in them. In time the acid softens the wood and causes the tanks to leak no matter how often they are tightened up. Some of our tanks have lasted as long as four years and given good service.

6. We have recently made some acid towers for one of the paper companies and they find Western fir satisfactory. This material comes in contact with sulphurous acid principally.

7. Wood filter-presses are almost invariably used for filtering acid mixtures. Considerable difference of opinion exists as to what woods are best suited for the filtering of various acids. We usually use paraffined hard maple. The plates are sometimes made of longleaf pine, oak, ash, and cypress.

8. We use an acid solution in our plant which is almost saturated with sodium sulphate and chloride. The acids present are sulphuric, sulphurous, and hydrochloric, the maximum strength being about 1 per cent. The temperature of the solution is about 30 deg. C., although in the leaching tanks 100 deg. is approached at times. We are using both Douglas fir and redwood. After three years of service both kinds of wood appear in good condition.

We also handle our waster smoke after passing through a scrubbing tower, through an exhaust fan built of wood. Under these smoke conditions the Douglas fir loses its strength and become black and soft. When there are no particular strains to resist, it lasts for several years. We are trying out redwood for this purpose and expect better results.

9. Fir will withstand the action of 18 per cent hydrochloric acid for about six months; North Carolina yellow pine will withstand the action of weak sulphuric acid up to about 5 per cent for one year, but even before that time, in case the acid is agitated, the wood begins to shred.

10. Most of our experience has been in handling hydrofluosilicic acid (H_2SiF_6) mostly at strengths of 10 per cent and 35 per cent The former solution is always handled at 100 deg. F. and the latter at atmospheric temperature. This acid has been used in wooden tanks made of fir, yellow pine, and cypress. We have also packed the 35 per cent acid in oak barrels. The wooden tanks are always lined with asphalt and the barrels with paraffin. None of these woods will stand the acid for any length of time unless the wood is coated with some lining. Whenever the acid is in contact with wood the alternate fibers are dissolved away, leaving the wood in a condition very much resembling a pad of paper.

Pipe made of tamarack was used for carrying 12 per cent hydrofluosilicic acid at a temperature of 100 deg. F. After three years' service it was still in good condition.

11. One of our lines conveys a solution containing 4 per cent or 5 per cent sulphuric acid. The pipe (tamarack) seems to remain as sound as ever.

12. While cypress gives better results for hot acids, yellow pine is superior to it for cold or warm acids.

13. Cypress tanks are used almost exclusively for acids and chemicals, and for hot liquids, as nothing else will give as lasting service.

14. Tamarack is a very satisfactory wood for silos, as it resists decay and the effects of the acids formed by the silage.

15. The pipe is made of white pine, selected free of all sap and other imperfections. We have furnished it extensively to acid factories, chemical works, vinegar and cider plants, for conveying vinegar, cider, and various acid liquors, such as dilute sulphuric, nitric, muriatic, and acetic acids.

16. Pipes made of white pine and tamarack are used for handling mine waters and dilute acids.

17. The lining of flues and hoods over acid vats (HCl and H_2SO_4) appears to last longer when made of spruce than of native pine (Massachusetts). This is probably due to the fact that the spruce is harder than the pine and does not disintegrate so rapidly around the nails.

18. We use cold HCl 3 deg. Bé, and boiling hot H_2SO_4 2 deg. Bé, and prefer old growth Oregon fir (Douglas fir).

Boehringer and Sons[16] use chlorinated compounds for coating and impregnating wood. It is claimed that substances possessing to a high degree chemical inertness towards acids, halogens, etc., are obtained when animal and vegetable oils, fats, and waxes, are chlorinated under such conditions as will insure the introduction of at least 30 per cent chlorine. Chlorinated products from mineral oils show a high degree of resistance towards the action of alkalis and acids.

American Iron and Steel Institute

The fourteenth general meeting of the American Iron and Steel Institute will be held at the Waldorf-Astoria, New York, Friday and Saturday, May 24 and 25. A business meeting for the election of seven directors to serve for the next three years was held Monday, May 6, at the office of the Institute, 61 Broadway.

[16]French Patent 433,415 (1911)

Defects in Industrial Rubber Goods

A Glossary of Defects with Suggestions as to Cause and Prevention

By Frederic Dannerth

OCCASIONAL claims for damages because of defects in finished products is an experience common to most manufacturing industries. This is obviously due to the fact that no product is perfect in the literal sense of the word. Hence *perfection* is only a relative conception, and the various tests applied to finished products are nothing more than methods used for determining how near perfect, the product is.

Defects may be due to the raw materials, to the processes of manufacture, or to the conditions under which the finished goods were shipped and stored. The fact that the goods were defective when they came into the possession of the consumer, is usually the form in which the complaint reaches the sales manager. So far as the writer is aware no attempt has been made to record concisely any of these defects in rubber goods, and it would seem that such an enumeration is especially desirable at a time when buyer and seller are making an honest attempt at understanding each other. A defect may be defined as "a property which impairs the value of the product, and renders it less fit for the purpose for which it was intended." If a perfect product be called *normal* the defective product may well be called *abnormal*, just as the physician applies these terms to persons who are sick or deformed. Following the analogy, it is possible to determine the cause, characteristics and remedy for each defect, and discover means for preventing its occurence.

Tackiness

This designation is given to the soft, sticky character possessed by low-grade, crude rubbers. In the case of raw Guayule this is due to the presence of resin to the extent of about 20 per cent, and the effect may be corrected to a considerable degree by simple deresination. In other cases the sheets of rubber are seen to melt and become semi-liquid when placed in the vacuum dryer; or, if exposed in a drying loft the sheets drop off the poles. This may be due to (1) depolymerization, (2) oxidation, by air and sunlight. It is probably not due to bacterial action or to the presence of carbohydrates.

Decay

It has been noted that crude rubber will *perish* or decay if exposed to oxidizing influences. In the case of low-grade rubbers the development of an acid smell is noticed, the rubber first softens and later becomes hard and brittle. This defect is induced by the action of heat and light. It should however be noted that rubbers rich in resins are not always the most liable to oxidation.

Loose-Sleeve Effect

This condition is noticed in the case of rubber-covered rolls. When the roll is put into service as part of a machine in the textile or the leather industry, the rubber compound works loose from the metal core of the roll. This may be due to careless vulcanization, or to the unsuitable character of the compound used for the "base," the part directly adjoining the metal. Aside

from this it may be due to the fact that the metal roll was not wiped free from grease, or the naphtha used for wiping the roll may have contained too high a percentage of non-volatile oil. In the latter case a film of oil remains on the metal core and the rubber compound fails to adhere to the metal. The defect may be avoided by eliminating the causes.

Defective Friction

This is noticed as poor cohesion between the plies of coated duck in the case of belting, hose, auto tires and the like. It may be due to (1) the moisture in the cotton duck, (2) the unsuitable character of the friction compound, or (3) to improper method of vulcanization. The defect is especially objectionable in the case of auto tires. Here the numerous pulling forces on the layers of cotton duck make severe demands on the friction compound. To avoid defective friction the indication is therefore to use a compound containing a sufficient quantity of good rubber and to dry the cotton fabric before it is coated.

Dry Friction

This is sometimes designated as "dead friction." It is due to the fact that not enough tacky binder has been used in the friction compound, or it may be due to over-vulcanization.

Boot Leg

This phrase is applied to belting, where the middle plies of cotton duck have become separated during use on the pulleys. It may be caused by dry friction, or defective friction or by the incorrect manner in which the belt was run on the pulleys. The edges of the belt remain connected, so that the belt appears as a hollow body open at each end.

Under-Vulcanization

Compounds which have been under-vulcanized, or under-cured, as it is called in the factory, are recognized as soft and flabby with negligible tensile strength and no marked elasticity. When such articles are stretched they do not come back to their original form readily. An expert would say that their "permanent set" or *permanent elongation* is high. Under-vulcanization may be due to (1) the use of an insufficient amount of sulphur, (2) the use of an insufficient amount of accelerator, (3) the short duration of the vulcanizing process, or (4) to the temperature at which the compound was vulcanized.

Over-Vulcanization

If a compound appears hard and stiff when removed from the vulcanizing chamber, this may be due to over-vulcanization (over cure). In this case the product would show good tensile strength, but it could not be stretched very far without rupture. Over-vulcanization should be carefully avoided, as it cannot be corrected, whereas in the case of under-vulcanized products, where the defect is due to too short a cure or to too low a temperature, this may be helped by subjecting the product to further vulcanization. The defect may also be caused by the use of excessive amounts of vulcanizer or vulcanization accelerator. It is especially undesirable in such articles as steam hose for railroads, steam packing, power-transmission belting and auto tire treads. As these products are subjected to high temperatures after they are put into use they should rather be slightly under-cured in the factory.

After-Vulcanization

This is seen in articles which contain an unusually large amount of free sulphur, or products which are subjected to high temperature while in use. The remedy or rather the preventive is to use less sulphur and less accelerator. At the same time the vulcanization should be effected rather by a long cure at a comparatively low temperature.

Slow-Vulcanizing Compounds

This defect is noticed in those compounds which contain a large percentage of retardants. These agents have a preferential affinity for the sulphur so that the rubber does not have an opportunity of combining with its allotted portion. If it is necessary to use retardants in order to produce a given effect in the finished product, care should be taken to incorporate in the recipe an accelerator as a corrective.

Dry Mixings

This is observed on the mixing mill during the mixing of compounds containing a large proportion of such dry fillers as whiting, infusorial earth, magnesia, asbestos and the like. In some cases a compound may mix easily on the mixing mill, but when fed into a tubing machine, the tube which is extruded (squirted or forced) through the die will have a tendency to crumble. In compounds which show these signs it is fair to assume that the absence of soft fillers has prevented the necessary cohesion and adhesion among the particles. It may be caused by the use of excessive amounts of dry mineral fillers or of reclaimed rubber. Reclaimed rubber stock containing as much as 50 per cent mineral matter, with 50 per cent rubber and organic matter is sometimes found to be very "dry" when run on the mixing rolls. The defect of dry mixings may be corrected by adding to the recipe such lubricators as black oil substitute, white oil substitute, petrolatum, unoxidizable vegetable oils, paraffin wax and pontianak.

Micro-Porosity

This defect is observed as small holes the size of a pin prick, which appear all through the finished product. It may be caused by the presence of air or moisture in the rubber dough previous to vulcanization. It may be corrected by the addition of paraffin wax, vegetable waxes, or asphaltum products to the recipe. If due to moisture, the mineral powders must be dried carefully before being used for compounding. The defect of micro-porosity is especially objectionable in articles which are to be used under pressure: air-brake hose; signal hose; vacuum hose.

Discoloration

This is observed as a grayish cast on products which were expected to come out a pure white or a bright red. For example, in cases where a high-grade white product is desired, zinc oxide is the preferred mineral filler. But if the zinc oxide contains lead compounds, an

impure white or even a gray product will be obtained, depending upon the actual amount of lead present in the mineral powder. As another example we have the case of crimson antimony sulphide, commonly used wherever a bright red-colored product is desired. If the antimony sulphide contains lead compounds, the resulting product will have a cloudy red color. The defect can be readily prevented by testing the zinc oxide and the antimony sulphide for the presence of lead before it is used.

Blooming

Of all defects observed in rubber goods, this is no doubt the most common. It refers to the separation of sulphur on the surface of the goods, and is still regarded by some buyers as a "good sign" of a well-made product. Salesmen frequently find it impossible to sell hose to some consumers unless the outside is liberally coated with sulphur crystals. This coating of fine sulphur is caused by a wandering of the excess sulphur to the surface. This is the free or uncombined sulphur. The bloom may be avoided by reducing the amount of sulphur in the receipe, or by using catalytic agents, or by reducing the amount of organic retardants in the recipe. If it is desired to remove the deposit from the finished rubber goods, this may be done by boiling the finished article in a weak solution of caustic soda. This operation is frequently carried out with rubber stoppers, which are to be used for chemical laboratory work. Bloom is especially objectionable in the case of articles used for food or medicinal purposes.

Blistering

If moisture is contained in the powdered mineral fillers, or in the raw rubber, this will produce the effect known as blistering when the compound is vulcanized. In extreme cases pronounced sponginess results. The defect in the majority of cases may be avoided easily by eliminating the cause. If the compound contains any substances which are volatile at the temperature of vulcanization, these will produce a similar effect. The plan then should be to avoid in rubber mixings any substances which might *volatilize* at a temperature of 300 deg. Fahr.

Ageing

This term is commonly applied to the drying-out or hardening of rubber products which are exposed to certain conditions. In the simplest case it is due to the recipe used, and for that reason the compounding man should be well aware of the conditions under which the compound is to be used, that is, the *specific* conditions. The ageing or surface hardening may be traced to any one of several fillers used in the compound, to the factors of time and temperature during vulcanization, or to the influences of temperature, light and air to which the finished product is exposed when in service. It has been difficult to devise a *laboratory* test which would take the place of the *service* test for this defect. And this fact in itself shows how difficult a problem it constitutes. One thing has been definitely established: the use of certain hydrocarbons in proper proportions will insure longer life for the product. These hydrocarbons include pitch products obtained from petroleum, coal tar and gilsonite, either alone or mixed. The decomposition, decay or death of a vulcanized rubber compound is influenced to a very considerable degree by the temperature to which it is exposed when in service. For that reason the life test usually applied in the laboratory to predetermine the liability of goods to decay consists in exposing the sample to definite higher temperatures for a definite time.

Swelling

This defect is found in packings used in connection with tanks where animal or vegetable extracts or fats are stored. Such substances as tanning extracts and beer extracts have a definite swelling action on some packings, and this is undesirable. Then again a hose used for conveying gasoline should not swell to any appreciable extent. This non-swelling property is secured by a careful choice of compounding materials, for it is a matter of common knowledge that rubber itself will swell appreciably when placed in gasoline (petroleum naphtha).

Permanent Elongation

This is observed in products which have been under-vulcanized, or which contain a very small percentage of new rubber, a large percentage of reclaimed rubber, or such gums as pontianak. Washed and dried pontianak contains possibly 25 per cent of actual rubber substance so that a compound made entirely of this will show little or no "come-back." In other words, the *permanent set* will be considerable. For example, if a test specimen be vulcanized and scribed with marks 1 in. apart, and the specimen then pulled apart in a testing machine, it will be noticed that the specimen will stretch to a considerable distance without rupturing, but when the pull is released the specimen will not return to its original position. The permanent elongation is excessive. For that reason pontianak gum exclusively is not used for the manufacture of commercial products. It may be stated as a general rule that the less permanent elongation which a product exhibits, the more valuable is the product. For this reason it has become common practice when drafting specifications to place a limit on the "permanent elongation."

Stretch

The ability to stretch and then come back and resume approximately its former position is a characteristic property of a well vulcanized, good rubber compound. Hard-rubber compounds are obviously excluded from consideration at this point, although they do show the physical property of *elasticity*. The percentage of stretch possessed by a rubber compound bears a certain relation to the amount of rubber which it contains. Hence it has become customary to carefully determine this property when the relative value of rubber products is to be ascertained. A finished rubber compound which will show little or no stretch is obviously defective, provided that the compound is intended for use where elasticity is an important factor. For it is quite possible to imagine cases where the compound would be used merely as an insulating layer, where the question of stretch would be relatively unimportant.

Tensile Strength

This is a property exhibited in varying degree by vulcanized rubber compounds, and it may well be considered a measure of the quality of the product. If

the strength is defective, this may be due to the use of an insufficient amount of sulphur, accelerator, or rubber; or the compound may be under-vulcanized or over-vulcanized. It may well be said that this property is one important indicator of successful manufacture. The interdependence of tensile strength and stretch must be recognized and taken into account at all times. If one is increased the other will be diminished, and the reverse is likewise true. The object then would seem to be this: To discover the one point in the vulcanizing process where the required amount of tensile strength is secured, and a maximum amount of stretch is obtained. For example, it is possible to specify that a rubber compound is desired which possesses a tensile strength of at least 300 lb. per square inch, and the stretch shall be not less than 1 in. to 7 in. If then a series of compounds all show a stretch of 1 in. to 7 in., that one will be the best which possesses the greatest tensile strength. For example, three different varieties of good rubber when vulcanized under the same conditions show tensile strength tests of 2830 lb., 3055 lb. and 3170 lb. It must, however, be added that this test does not indicate whether the life of the compounds is in the same ratio as the tensile strength figures.

The Rubber Trade Laboratory,
Newark, New Jersey.

Manufacture of Nitric Acid

AT A MEETING of the Delaware Section of the American Chemical Society at Wilmington on March 8, Dr. Edward Hart of Easton, Pa., delivered an address on nitric acid. Dr. Hart is one of the pioneers in the distillation of nitric acid and the inventor of the Hart condenser. He said it had been his lot at various times to be called into consultation by men of affairs, heads of manufacturing industries, in such a way that he could gage with a fair degree of accuracy the methods they were pursuing. He said he had never come in contact with men organized on better lines or pursuing methods better calculated to bring success than those of the chemical organization which overshadows Wilmington.

One little seed which he planted there many years ago has grown under its fostering care, he said, and has developed until the old boy who planted it can scarcely recognize his child.

There has developed, too, one of the humors of the situation, for what has come to him of the methods of operating, has come through roundabout channels, and he had never seen his nitric acid plant running in Wilmington.

About the year 1893, in response to a request from the du Pont de Nemours Company, he visited Wilmington, aw Mr. Jackson, and sold him six condensers. Shortly after he turned the propaganda work over to others and devoted himself to purifying nitric and hydrochloric acids for which he invented automatic apparatus, still industriously at work.

Out of those six condensers with ½-in. tubes have been developed the present batteries which for several years have been turning out the sea of nitric acid that is so potent an instrument in our chemical transformation as a nation.

In taking up the history of nitric acid, Dr. Hart referred to the preparation by the latin Beber (Nuremberg edition, 1545), which seems to have been the first. Georg Agricola described its preparation in the first edition of De Re Metallica (Hoover's Trans.). Lazarus Erckers described the preparation of aqua fortis in 1574 in The Beschreibung aller Fueremsten mineralischen Ertzt und Bewercksarter (also in edition of 1580). Glauber, after whom Glauber's salt is named, was the first to prepare hydrochloric acid from salt and sulphuric acid. He also prepared nitric acid from saltpeter and sulphuric acid, although he did not directly describe either process. Caspar Neumann also described the preparation of nitric acid from niter and sulphuric acid (Trans. by Wm. Lewis in 1759). In 1848 Dumas also described its preparation in Traite de chimie applique aux arts, Tome 7, p. 283.

About 1890 Dr. Hart began to make nitric acid. At that time the firm of Baker & Adamson, in Easton, Pa., of which he was a member, had been buying nitric acid and refining and selling the chemically pure article. The acid came to them on flat cars in carboys

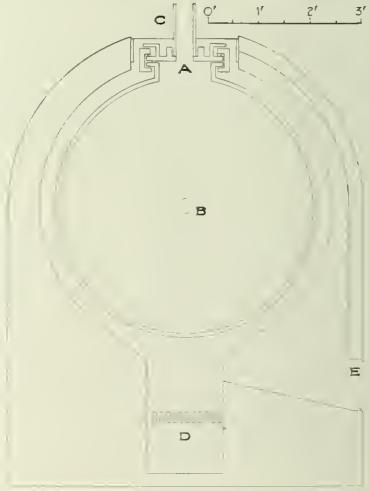

FIG. 1

Hart's Nitric Acid Retort.

and they had so much trouble from breakage and so many of the men were burned that they decided to make their own acid from nitrate of soda and oil of vitriol, 66 deg.

Being dissatisfied with the retort figured in the books, Dr. Hart devised one very much like that shown in Figure 1, 4 ft. diameter and 4 ft. long. It had about eight ½-in. holes bored in the top plate, and after the charge was made eight Liebig glass condensers were fastened in the holes, four on each side of the furnace. Then the fire was started and the trouble began. A 2-gal. bottle was placed under each condenser and soon

yellowish-red fumes of nitrosyl chlorid were pouring from each bottle and forming a pool in the room. It was evident that the condenser system would not do, but it was not until some time later that the first Hart condenser was devised, erected, and patented. At first they had a great deal of trouble with boiling over until it was discovered that the two boys running the apparatus were systematically forcing the fire so as to make it boil over to get short hours. After replacing them this trouble disappeared.

Dr. Hart's first publication on the subject was in the *Journal of Analytical and Applied Chemistry*, of which he was the editor (Vol. 5, 1891, p. 382). Two papers were then published simultaneously in the *Journal of the American Chemical Society* which he then edited (Vol. 17, 1895, pp. 576, 580). In these papers he dealt with condensation generally and described the condenser as patented. It had fifteen 1-in. tubes 6 ft. long and condensed 785 lb. acid from 1000 lb. niter and 1000 lb. oil of vitriol, 66 deg., in six hours actual running time with 150 lb. pea anthracite coal.

According to the census of 1900 the production of nitric acid in the United States was about 15,500 short tons, most of which was used in the manufacture of nitroglycerine and guncotton. This has, of course, vastly increased and, since the great war began, by leaps and bounds. Dr. Hart pointed out that until nearly 1900 there were only a few large producers. Most installations were of only one or two retorts, and little effort was made to save the bleeder gases (mostly NO_2). The conversion of this gas into HNO_3 is a difficult operation, for it involves absorption in water and oxidation with atmospheric oxygen. Since the latter is mixed with four times as much nitrogen and is only slightly soluble in water, large surface is required and high yield can hardly be expected. This part of the subject is best studied in connection with synthetic nitric acid. He called attention to the Guttmann process in which thin earthenware tubes are used for condensation and the Valentiner process in which distillation takes place in a vacuum. He has already detailed these methods in the article on nitric acid which he wrote for Sir Edward Thorpe's Dictionary of Applied Chemistry. The latest method is that of Hough, who uses a duriron condenser. Most of the acid from Chile saltpeter is being produced in some modification of the Hart condenser. The latest form of this apparatus for large installations is shown in Figure 2. In the early condensers asbestos was used as a lute between tube and manifold. This has been displaced by putty. Dr. Hart did not know who invented this putty, nor who devised the pulsometer and dash pot operated with compressed air used for the condensing towers.

There is one property of nitric acid which demands special attention. Under certain conditions it is a strong oxidizing agent and since one set of products of the operation is nitrogen oxides which may be regenerated it is entirely possible that this will repay further study.

If cotton is treated with strong nitric acid, we get nitric esters. The oxidizing action is negligible Since cotton may be considered an alcohol, we should expect the same result from other alcohols. With ordinary ethyl alcohol we do in fact get ethyl nitrate, but this manufacture should not be attempted on a large scale the first time. If all oxides of nitrogen dissolved in the nitric acid are destroyed by adding a little urea the reaction then goes smoothly and we get pure ethyl nitrate. Without the urea we might go out the door by way of the window. When aromatic compounds like benzene are treated we get a different class of substances: the nitro compounds, in this case oil of myrbane. The oxidizing effect which is of the third class is most pronounced when the nitric acid is diluted. For example: strong nitric acid and phenol give the nitrophenols. But dilute nitric acid boiled with phenol gives beautiful yellow crystals which on examination are found to consist almost entirely of oxalic acid.

Dr. Hart said if he ever gets the time he wants to see whether it is possible to make oxalic acid in quan-

tity from cheap organic material, like sawdust for example, by boiling with dilute acid and regenerating the oxides. To all intents and purposes, working in this way we would get our oxidation at the expense of atmospheric oxygen. This would be an especially attractive idea where waste power is available, for example where power is used for operating trolley lines where the peak comes at 6 a. m., 12 m. and 6 p. m., with practically no load from 12 p. m. to 5 p. m. During the five-hour interval of no-load the power would be at work generating oxides of nitrogen to compensate for unavoidable losses.

He said he was satisfied that fields like this will yield a rich reward to the successful cultivator, and that as the years go by nitric acid, ammonia, and the other nitrogen derivatives will play a larger part in our future.

In this connection an interesting article by W. Ed

Burkhard has just appeared in the March number of the *General Chemical Bulletin* which will supplement very well the data given by Dr. Hart. Mr. Burkhard says that without this acid we should not have all our beautiful variegated artificial colors and dyes but would be limited to the comparatively few serviceable natural dyes; we should also be without some of our finest lacquers, artificial silk, collodion, celluloid, nitroglycerine, dynamite, T.N.T. and so on for an almost unending list of extremely valuable materials. He says that until very recently all the commercial nitric acid in the world was made from saltpeter brought from Chile.

The refined nitrate as used in acid manufacture has from 92 to 98 per cent $NaNO_3$, generally 95 to 96 per cent. For this purpose it should not contain over 1½ per cent NaCl as in the distillation the muriatic acid formed destroys an equivalent amount of nitric acid.

The commercial manufacture of this acid started in this country in 1824. However, this industry did not assume any importance until the discovery of nitroglycerine in 1862, since which time the money investment and labor used have steadily increased until in 1915 the United States produced nearly 80,000 tons of nitric acid at fifty-two works and 112,000 tons of mixed acid at thirty-seven works. The world demand for nitrogen compounds has risen to 750,000 tons a year.

There are three general methods for manufacture of nitric acid now in successful use—the continuous, the vacuum, and the atmospheric pressure. The last is the one in most general use.

In the continuous process, which was successfully used in England, the nitrate is mixed with an excess of H_2SO_4 in a separate vessel where solution is effected and chlorine and nitric oxides are given off. This mixture flows continuously into a still which is heated, effecting distillation of all the nitric. The residue in the still is drawn off at frequent intervals. They claim the distillate to run 94 per cent nitric acid of a fine quality and a "soup" of 30 per cent H_2SO_4. However, in spite of all the good qualities claimed and seemingly theoretical advantages, the process does not seem to have found favor in America. The "nitre soup" is the residue in the still after the nitric is distilled off. It consists of sodium sulphate with from 20 to 30 per cent free H_2SO_4, very often approximating an acid sulphate, *i.e.*, $NaHSO_4$.

The vacuum or Valentiner process is successfully used in this country to some extent. This process is identical with the common atmospheric process except that it is operated under a vacuum which, of course, means a lower distilling temperature. However, in order to expel the last trace of nitric acid the final temperature is nearly the same in both cases, approximately 175 per cent—250 per cent C. In the vacuum process all leaks suck in air, thus rendering more difficult the complete condensation of the acid, but the plant is remarkably free from fumes, which is an important factor. Also, a gang of repair men must be constantly on the alert, for leaks do not show themselves as in the common process.

The soda and acid, generally 66 deg. Bé. H_2SO_4, though stronger acid is sometimes used, are charged into an iron still. The size and design differ widely. The sulphuric acid is usually calculated so that the "soup" will be as fluid as possible at as low a temperature as practical to prevent excessive corrosion. The normal acid sulphate fulfils these conditions. The heat is applied gently to the stills to prevent boiling over and the gases are condensed. By fractionating the condensate, acids of various strengths and purity are recovered. The impure acid is purified from its volatile impurities such as iodine, chlorine and nitrous acid (which gives it color) by bleaching, which is simply boiling and drawing off the impure vapors.

The process for the future is the synthetic, which promises to put the soda or decomposition process in the second place. The raw materials, air and water, are to be had for the taking. Since the war started Germany has been denied all imports of soda and so would have been quickly forced to the wall for lack of explosives had her chemists not risen to the occasion and made practical the industrial synthesis of this acid.

Most nitric acid is used for nitrating, that is, introduring the NO_2 group into organic compounds. As this action produces water, the acid is quickly diluted and loses its power. To overcome this mixed acid is used. This is a mixture of either ordinary or fuming sulphuric acid with different strengths of nitric.

The greatest demand is for high-grade acid of between 36 and 44 deg. Bé., *i.e.*, 52 to 74 per cent acid, although as low as 30 deg. is made. Also, one grade over 52 deg. is made, which is very strong nitric saturated with N_2O and is called fuming. It is claimed to have greater oxidizing power. Nitric acid can only be satisfactorily shipped in glass carboys, although mixed acid can be shipped in steel tanks.

Production of Platinum in the United States in 1917.—According to figures compiled by J. M. Hill, of the United States Geological Survey, Department of the Interior, only 605 ounces of crude platinum was sold by placer mines in 1917. This is less than the sales in 1916 by about 100 ounces. The imports of crude platinum amounted to 31,921 ounces, not counting the 21,000 ounces of Russian crude platinum which was received by the Government late in December.

During 1917 refiners made about 33,000 ounces of platinum, 4,800 ounces of palladium, 833 ounces of osmiridium, and 210 ounces of iridium, which can be called "new metals." Of this amount about 7,400 ounces probably originated from domestic materials.

The saving of scrap platinum of all classes resulted in much larger recoveries of secondary platinum metals than in previous years, a total of 72,000 ounces being recovered, as compared with 48,000 ounces in 1916.

Potash from Seaweed in South Africa.—Mr. Gilbert F. Britten, in the course of a paper contributed to the South African *Journal of Science*, says that of the enormous growths of seaweed along the shores of the peninsula, experiments indicated that the kind known as "sea bamboo" could be utilized for the production of potash. It was found that there were not, generally speaking, very great differences in the chemical composition of the various specimens, and while South African bamboo is on the whole lower in potash content than American kelp, it is decidedly better in composition and may prove a worth-while source of potash.

Potash from Wood Ashes

Production in Michigan and Wisconsin

By C. T. EDGAR[1]

ON March 2, 1917, a number of potash manufacturers from Wisconsin and Michigan met at Wausau, Wisconsin, to organize for their mutual interests. These men formed the Northern Potash Association, which includes in its membership upwards of twenty potash plants.

The primal purpose for the meeting at this time was to deal with tariff problems, which greatly concern the future of the industry. But equally important was the need of co-operation, and the discussion of many matters in relation to an industry that has developed in somewhat mushroom fashion, yet up to the present has remained disorganized. By that I mean as well that the industry in this country as a whole has remained disorganized.

The Association referred to is sectional, and while it probably comprises the majority of those connected with the manufacture of potash from wood ashes, the total production from that source is still small, and its development has been inconsiderable compared with that of certain other fields, such as California and western Nebraska. The Northern Potash Association is endeavoring to encourage the organization of manufacturers in other sections of the country, to increase production where practicable, aand to assist the Government in any way that it can for the carrying on of the war. Its efforts have met with a gratifying spirit of co-operation.

The amount of potash produced in wood ash plants is not large, comparatively. But the number of such plants has greatly increased, and this increase has been made for the most part in the short space of two years. From three or four plants doing business in the early period of the war the number of such plants is now increased to around fifty in Wisconsin and Michigan alone.

Exact production figures for this district are not yet available. A representative number of plants, however, report an output ranging from 1500 lb. to 4000 lb. a week at each plant. The average is closer to the smaller figure. A conservative estimate would place the production of potash salts in Wisconsin and Michigan at 3,900,000 pounds annually, having a value of $1,170,000 at present prices.

The recovery of potash from wood ashes was quite an extensive method of manufacture at an earlier period. Some idea of this production may be gained from the fact that in 1850, 27,000,000 lb. were exported from Canada alone. Since 1870 the wood-ash product has been largely displaced by the mineral salts from the German deposits.

The crude form of potash produced from wood ashes is known to the trade as "potash first sorts." It consists of a soluble portion of wood ashes, obtained by a process of lixiviation. The salts are dissolved by soaking the ashes in water and drained off through a lime filter, after which the solution is evaporated and reduced to solids by heating. The product is usually sold in tight wooden barrels containing from 600 to 800 pounds to the barrel and is in the form of fused, chunky masses, having something of the appearance and hardness of stone. It absorbs moisture and will become liquid if it is exposed to the air long enough. The color is a greenish gray, with variegated hues of red, brown and blue. The coloring is due to small portions of iron and manganese, and carbonaceous impurities.

The equipment necessary for producing these salts is inexpensive and very simple. I have known many instances in which persons entirely unfamiliar with potash have constructed plants and put their product on the market within thirty or forty days after their interest was first attracted to the business.

The usual cost of a plant is about $3000. The general plan consists of an elevated platform supporting tubs, or leaches as they are called, and a "melting" room which contains the furnace and kettles. The leaches are usually from twenty to thirty in number, either square

[1]President, Northern Potash Association.

FIG. 1. POTASH PLANT AT ANTIGO, WIS. THE ASHES ARE LOADED AND REMOVED THROUGH THE SMALL DOORS ON THE SIDE OF THE BUILDING

FIG. 2. [illegible]

FIG. 3. MELTING ROOM, ANTIGO POTASH CO. ON THE LEFT IS SHOWN THE KETTLE IN WHICH THE "MELT IS COMPLETED AND THE TWO IRON MOULDS"

or round, constructed of wood with sloping metal bottoms. The round leaches, or tubs, are preferable to the square boxes, because when rotted or old they can be removed and replaced separately without interference with the adjoining leaches. They are about 4.5 ft. high and 5 ft. wide and are preferably arranged in rows on either side of the platform. This permits the used ashes to be thrown from them through little openings on the exterior walls of the building and on to wagons or conveyors, whence the leached ashes can be taken to the place of dumping.

Frequently the space through the center of the room between the rows of leaches is used for storing ashes and in the ordinary plant will conveniently store 100 tons or more at a time. Beneath the platform are metal troughs on each side running the length of the rows of leaches. The bottoms of the leaches should slope so as to be 4 to 6 in. lower at the side situated over the trough. Small holes are bored on a level with the lower ends of the leaches so as to permit the liquid to drain from the leaches into the troughs.

Before filling the leaches the filter, consisting of straw and lime, is placed on the bottoms. Rye straw is preferable. After the straw is laid on a thickness of several inches, slack lime is smeared over the surface to the extent of one inch. The leach is now ready to be filled with ashes. The ashes should be tamped down as uniformly as possible so as to insure perfect soaking. Water is run over the leaches several times a day for about four days. The ashes continue to soak up water and a process of fermentation is going on. After this period a reddish-brown liquor begins to drip from the bottoms of the leaches into the lye troughs. The ashes are watered two or more times a day and the liquor continues to drain from the leach for a period of eight to ten days after it has started to run. By that time the solution becomes weaker, the old ashes are thrown out and the leach freshly filled. The filling of the leaches is generally done in rotation so as to maintain a constant flow of lye. The strength of the ashes of any particular leach can be easily determined by the use of an alkali hydrometer, by taking the specific gravity of the lye which flows therefrom. The lye from a fresh leach will test around 20 per cent. When the test shows only one or two per cent the leach should be discontinued and the ashes thrown out.

The lye flows through the troughs into the "melting" room into evaporating pans or kettles, which for several days are kept constantly full. The evaporation is facilitated by the heat from the furnace which is usually waste heat so directed as to pass under the evaporating pans. As the solution becomes thicker it is transferred into a larger kettle, which is fitted over an enclosed brick furnace. The mass is now subjected to a powerful heat for a number of hours during which gaseous matter is driven off, combustible impurities are for the most part burnt out, and a fusion takes place. When the fusion is complete, the liquid becomes quiescent, and has a reddish glow like melted iron. It is then transferred, by means of large iron ladles, to iron pots and congeals in cakes. The pots are usually of such size as permit the cakes to fit into barrels for shipment.

The proportion of potash contained in wood ashes is not constant. The analysis of the potash salts therefore varies considerably in the proportions of potash compounds. The greater portion of these salts, however, consists of potassium carbonate, particularly in a converted form of potassium hydroxide, due to the contact with lime. An analysis follows:

Potassuim Hydroxide	65.64%
Potassium Carbonate	16.58%
Potassium Sulphate	16.03%
Potassium Chloride	.35%
Moisture and insoluble	1.40%
Alkalinity as Potassium Hydroxide (K_2O)	79.10%

The price of ashes in saw-mill localities and wood-burning communities varies from $2.00 to $6.00 a ton. About two cubic yards, not compressed, comprise a ton. Hardwood ashes are preferred to those in which the ash of soft woods predominates for the reason that the principal hardwoods apparently contain a greater percentage of potash. Woods' Dispensatory contains a table indicating the percentage of potash recovered from the ashes of various plants. It is stated therein: "Ligneous plants yield less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood, and the leaves of trees which drop their foliage in winter yield more than the leaves of evergreens." Following is the table referred to:

Pine	0.45
Poplar	0.75
Birch	1.29
Beech	1.45
Oak	2.03
Box	2.26
Willow	2.85
Linden	3.27
Elm	3.9
Maple	3.9
Wheat Straw	4.18
Flax	5.0
Rush	5.08
Common Thistle	5.37
Vine Branches	5.5
Barley Straw	5.8
Beech Bark	6.0
Fern	6.2
Indian corn stalks	17.5
Sunflower stalks	19.4
Dry oak leaves	24.0
Common nettle	25.0
Black elder	25.5
Vetch	27.5
Poke	45.6
Wheat stalks	47.0
Stems of potatoes	55.0
Worm wood	73.0
Fumitory	79.0
Angelica	96.2

One difficulty of the wood potash maker is in the conservation of the ashes. He finds that the people who make the ashes are not greatly interested in saving them notwithstanding that the price may be high. Many economical improvements could be made were the business a permanent one, but the potash makers have thought it was a business that would be killed by foreign competition some time following the close of the war and are therefore unwilling to make improvements.

Wausau, Wis.

Fulton's Electric Zinc Furnace

THE METALLURGICAL LABORATORIES, Inc., has been experimenting for about a year and a half with the zinc-smelting process devised by Dr. Charles H. Fulton of Case School of Applied Science, and patented by him early in 1916[1]. During the twelve months following September, 1916, Dr. Fulton personally directed the experimental work at East St. Louis, with satisfactory results. At the present time the plant contains an intermittent furnace of commercial size, operating on various oxide and silicate ores, determining the proper mixtures for briquetting, the current requirements, and the condenser design capable of liquefying the tremendous volume of vapor produced. The furnace now in operation is practically that described in patent No. 1,242,337 (Oct. 9, 1917), which, together with others recently granted (1,242,339 to 41, and 1,249,061), gives a large number of details concerning their experiments.

With reference to Fig. 1, the furnace is an electric resistance furnace, consisting of the movable cylindrical steel shell (1) closed at the top, lined with refractory material, and the open bottom resting on a fixed base *B*, the passages 10 being heated by a gas flame. The dried ore, with suitable binder, is formed into briquets which constitute the resistors, and the electric current passing therethrough generates sufficient heat to raise the interior to such temperature as is necessary for the reduction of the zinc compounds and the vaporization of the metal. The finely divided zinc-bearing material (ore, blue-powder, or ashes) is mixed with pulverized coke for a reducer, and sufficient binder is added (tar or hard-coal tar pitch) to thoroughly coat the particles.

Coke is the best reducer because it contains little volatile matter to be driven off preliminary to distillation, and gives off no gas during distillation. The particles also retain their form during the process, thus insuring the continued stability of the briquet. The relative proportions of coke and ore should be such that sufficient porous material will remain at the end of the heat to insure substantially the original volume of the briquet, and constitute from 40 to 50 per cent of the original weight. Binder to the amount of 12 to 15 per cent of the weight of the ore plus coke is sufficient if the latter is moderately fine, i.e. will pass through a 10-mesh screen. The proper determination of the coke size is important, as fine coke produces strong briquets, but of low electrical resistance.

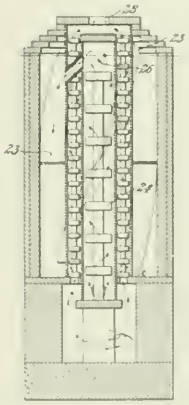

FIG. 5

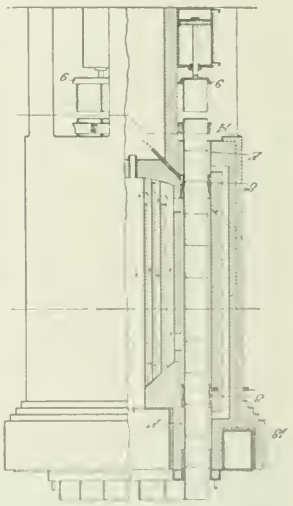

FIG. 6

The hot mixture is compressed into rods, 12 inches in diameter and six feet long at a pressure of from 500 to 1000 lb. per square inch. They are then preheated in order to coke the binder and drive off the hydrocarbons before distillation begins. The briquets are properly supported during this process in order to maintain their shape; a neutral or reducing atmosphere is also essential to prevent the coke at the surface from burning and loosening into a friable layer.

The briquets may more easily be made in shorter sections, and cemented together at the ends by a mixture of 40 per cent of coal-tar pitch, and 60 per cent of fine graphite. In any case the final briquet is placed on end upon an electrode energized through leads built into the fixed bottom of the furnace. Top and bottom connections for a 3-phase star connection are shown in Figs. 2 and 3, the connectors being made of graphite (or of the ore-coke mixture) and pinned

[1] A short description of the original patent was given in this Journal Feb. 1, 1917, p. 158

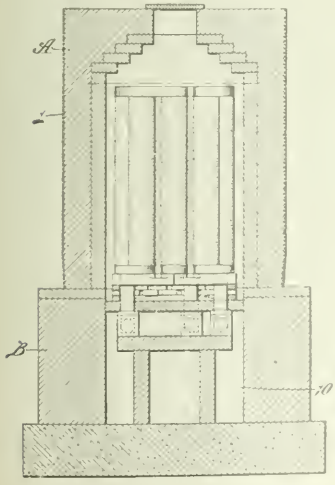

FIG. 1

FIG. 2

FIG. 3

FIG. 4

to the top of the resistor as shown in Fig. 4. In this diagram 3 represents a filling of fine graphite; the construction being designed so that there is small danger of an open circuit at these points due to differential shrinkage of adjoining columns.

In operation, the baked briquets are assembled upon the bottom electrodes, and the top connections made. A preheated retort *A* is lowered over the whole, and current switched on. The energy input is relatively small until the whole interior of the retort reaches a temperature of from 700 deg. to 800 deg. C. when the current is rapidly increased until the distillation point is reached. The products of the reaction, zinc and carbon monoxide vapor in equal volumes, are drawn off in a quite pure condition through openings at the top of the base and discharged into a suitable condenser set nearby. A complete cycle requires 5½ to 6 hr., when the distillation is practically complete.

As can readily be imagined, the problem of condensing the zinc vapors is of extreme importance. Several designs of electric zinc furnaces can produce zinc vapor in large quantity, but none of them has been able to produce the proper yield in liquid metal —the vapor apparently solidifies as the solid blue-powder without passing through the liquid phase, much as happens in the formation of frost. In order to condense from a vapor, the temperature of the gas must be lowered beyond the boiling point of zinc at the partial pressure of the mixture, 870 deg. C. at ½ atmosphere, which exists when Zn and CO are present at equal volumes. The liquid product must not solidify; the absolute temperature minimum is therefore the melting point of zinc (419 deg. C), while the working minimum is more like 550 deg. C. or 600 deg. C. Another important consideration is the amount of surface necessary for the condensation of a given quantity of vapor; so-called "nuclei of condensation" are necessary. That is, if there be provided in a space a large number of points or "nuclei" upon which the vapor has condensed into a liquid, these small particles of liquid already formed facilitate the further condensation of the vapor. Some surface must now be provided for the "nuclei" to gather upon, and the liquid to coalesce into droplets.

As remarked above, electric smelting of zinc has produced considerable "zinc frost" or blue-powder. This may be due in some cases to the production of a zinc vapor mixed with a variety of other gases. The partial pressure and boiling point of zinc in the mixture is therefore lowered, and consequently the temperature limits of successful condensation are more narrowly restricted. Again, local hot spots or small arcs in the charge may vaporize minute quantities of other metals or metalloids which solidify almost immediately, forming a plethora of condensation nuclei. Or due to slightly oxidizing conditions existing in the condensing gases at the reduced temperatures, the tiny droplets may become sufficiently oxidized on the surface that they do not coalesce into a liquid.

Whatever may be the actuality of these controversial points, the condensers operating on Dr. Fulton's retorts will have to overcome them, and in addition absorb and radiate a great quantity of heat continuously. Supposing each retort to hold 12 briquets, each weighing about 600 pounds, and containing about 20 per cent zinc, which is entirely distilled and condensed in six hours, liquid zinc would form at the rate of 240 pounds per hour. Not counting the amount of heat radiated by the hot mixture of gas cooling from the temperature of the retort (1000 deg. C. to 1300 deg. C.) to that of the condenser (600 deg. to 800 deg.) the latent heat of vaporization of the zinc at the lower temperature (1,051 B.t.u. per pound) will amount to 252,000 B.t.u. per hour. Although Dr. Fulton's process gives a cleaner vapor than many other proposed schemes, actual figures on the real condensation accomplished would be very interesting.

Two condenser designs are illustrated in the patents, one being shown in Fig. 5. It consists of a central shaft containing several baffles (24). The gases from the retort ascend through this shaft, then into the outer chamber 23 where they are deflected up and down by spiral partition walls, the uncondensed gases finally escaping through openings 26, where the carbon monoxide may be utilized. In order that the condenser may operate within the rather narrow temperature limits necessary, the annular checker chamber between these two chambers may be heated by gas flames (or cooled by air blast as necessary) entering below and escaping through the top 28.

A continuous furnace and process is also described and patented (1,242,339 and 40) illustrated in Fig. 6. The annular furnace contains a series of briquets heated by the passage of electric current between the electrodes 8 and 8*a*, where sliding contact is maintained by granular graphite. As distillation proceeds, fresh briquet sections are fed into the distillation zone by the action of a plunger 9 and supporting clamp 14. Spent hot electrodes are removed from the top and set in the trough 18 alongside freshly made sections, to dry the latter. Further baking is effected as the briquet passes through chamber *E*, where a gas flame is maintained, together with chamber *F;* this also acts as a seal preventing oxygen entering the distillation chamber. The products of the reactions are drawn inwardly to the central condensing chamber shown.

These novel processes have many unique features which apparently offer advantages. The temperature of distillation can be controlled either by voltage regulation, or by changing the speed of the briquets travelling through the continuous furnace. This should lend itself to the production of zinc relatively free from cadmium or other impurities, as the cadmium-rich product could be collected and withdrawn early while the furnace is at a low temperature. The time of distillation, heat input and labor cost have been reduced to a minimum.

High-Grade Abrasives—Tremendous expansion in manufacturing in 1917, particularly in the steel and metal industries, is reflected by the increased production of high-grade abrasive materials in the United States. A preliminary compilation by Frank J. Katz, United Seates Geological Survey, of reports on the production of emery, corundum, and artificial abrasives in 1917 indicates a total of 72,276 short tons, valued at $8.325,312, which is an increase of 33 per cent in quantity and 172 per cent in the value as compared with 1916. About 80 per cent was artificial abrasives.

Stellite

Alloys of Cobalt, Chromium, Tungsten and Molybdenum

By Elwood Haynes

It is a noteworthy fact that the metals found in their native state on the surface of the earth are, generally speaking, extremely rare. Besides meteoric iron and native copper, they include gold, silver, mercury, and the metals of the platinum group. If Nature produced other metals during the formation of the earth's crust, they have long since combined with other elements, and exist only as compounds, chiefly oxides, sulphides, arsenides, carbonates, chlorides, etc.

It is extremely desirable, however, to have for use metals or alloys which remain permanent under atmospheric conditions, and at the same time have such physical properties as will enable them to be manufactured into instruments and utensils for daily service. Metals which are not at all permanent in the air, such as iron, lead, mangenese, etc., produce compounds with oxygen or sulphur which remain practically unchanged under ordinary natural conditions for many centuries, but these compounds are not workable, nor in any way suitable to direct manufacture into implements for daily use. Their physical properties, such as strength, hardness, and workability, are not such as would recommend them for such instruments. Copper, alloyed with zinc, produces brass, and olloyed with tin, produces bronze, but none of its combinations is permanent in the air, and all of its alloys are inferior in strength and hardness to steel.

The so-called "noble metals" with the exception of silver, are permanent in the air, but are so rare that implements made of them would be extremely costly, particularly if of any considerable size.

Desirable Qualities Sought in New Alloys

It was with a view to producing an alloy which would combine the permanence of the noble metals with the strength and hardness of steel that the writer made a long series of experiments, which finally resulted in the production of a series of such alloys.

As early as 1899, an alloy was produced by heating the mixed oxides of chromium and nickel with metallic aluminium. A small button was obtained which showed considerable malleability when cold and when polished exhibited a bright luster which was not dimmed when the metal was boiled in either strong or dilute nitric acid. Moreover, the acid showed not the faintest color after such test. This alloy was somewhat harder than untempered steel, and could be readily worked under the file or in the lathe.

The mixed oxides of cobalt and chromium were afterward reduced by the same method, but the little pellets of the alloy thus produced were thrown from the crucible by the violence of the reaction. A few of these were collected, and found to be very much harder than the corresponding nickel alloys. They showed the same resistance to nitric acid and were only attacked very slowly by hydrochloric and sulphuric acids.

Later, the mixed oxides were reduced by means of carbon, and it was found possible to cast the alloy into bars which showed remarkable strength, rigidity, and hardness, as well as complete immunity to all atmospheric influences. Polished samples of the alloy were exposed to the fumes of the chemical laboratory for months, and in some cases their surfaces became covered with a deposit of ammonium chloride, but this could be easily rubbed or washed away, and the alloy showed the same brilliant surface as before.

These binary alloys of cobalt and chromium were so hard that they would take a cutting edge, and could be used in the place of steel for pocket-knife blades and table knives. They were found to be malleable at a bright orange heat, even when the chromium content rose to forty-five per cent or more. These high chromium alloys were very hard to forge, but after forging into pocket-knife blades, for example, they showed extremely fine grain, high elasticity, and a hardness equal to that of the best quality of steel pocket-knife blades. The permanence, general utility, luster, and color of these blades are very remarkable.

An Alloy Rival of Steel

This alloy may be truly termed steel's first rival, since it constitutes the first metallic combination yet discovered, so far as the writer is aware, which takes and holds an edge at least equal to that of the best steel, and at the same time it can be produced in almost any form in which steel is utilized. It is of course much more costly, owing to the high price of its constituents. This, however, does not preclude its use for the following articles: a. table knife blades; b. pocket cutlery; c. surgical instruments; d. dental instruments; e. small evaporating dishes; f. spoons, forks and scissors. Lancets made of this hard alloy are now in use by many expert surgeons, and are proving highly satisfactory for this purpose, since they are immune to all antiseptic solutions employed in surgical work, and at the same time take a keen edge, equal to that of the best tool steel.

The first paper was read on the binary alloys of cobalt and chromium, before the American Chemical Society, in 1910, at San Francisco.

ARTICLES MADE FROM STELLITE

Later, the elements tungsten and molybdenum were introduced into this alloy, either of which increased its hardness to a remarkable degree. In fact, alloys of this character can be made so hard that they will scratch any steel yet produced.

Nature and Properties of the Alloys

Just what is the nature of these combinations has not yet been fully determined. They seem to consist, however, of a cement of the hard cobalt-chromium alloy, which binds together minute crystals, possibly composed of the double carbides of chromium and tungsten or chromium and molybdenum. The above is little more, however, than a conjecture, as no real proof of such an assertion has yet been made.

These alloys can be readily cast into various forms, and melt at a lower temperature than the binary alloys of cobalt and chromium. The most remarkable property of these triple alloys is their ability to retain a cutting edge at high temperatures, and it is for this reason that they excell all high-speed steels in their ability to perform rapid work on the lathe.

Lathe speeds which would instantly destroy the edge of the best high-speed steels can be readily maintained with stellite tools without injuring the cutting edge. This advantage is so pronounced that stellite is coming into very extensive use as a substitute for high-speed steel tools, notwithstanding its comparatively high price. Machine shop superintendents and production men generally, are keenly alive to the fact that because other costs in the manufacture are so much greater than that of the tools, they are fully justified and save large sums of money on labor, equipment, floor space, and so forth by using highly efficient tools.

The following articles have been made from the hard alloys: lathe tools, milling cutters, saws, drawing dies, boring tools, drills, etc. These tools must be cast to the proper form, as they can not be forged nor otherwise manipulated except by grinding. At first sight, it would seem desirable that the tools should be of such a nature that they could be tempered and forged, but a moment's reflection will render it evident that such a property would be detrimental, since in order that it might be forged, it would be necessary that it should soften under heat and would thus lose its most valuable property. The same would be to a certain extent true regarding tempering or hardening, since it is the inherent stability of the alloy at all temperatures which gives it its highly desirable qualities as a lathe tool.

At the instant of casting, and just as the metal is changing from the liquid to the solid state, minute crystals of extreme hardness are formed, and these crystals remain unchanged in their properties under practically any series of temperatures below the melting point of the alloy. Prolonged annealing does not soften it, and it is not hardened by heating it to a high degree and quenching in water. It does not take up carbon to any appreciable degree, even when surrounded by carbonaceous material in a closed vessel for days at a bright orange heat, say 1000° C. or more.

All of the polished alloys, when heated in an open fire, take on a thin film of oxide, which finally terminates in a deep blue-black color. This oxide is so firmly adherent that it absolutely prevents further oxidation of the metal, so that even though the sample may be heated for days at this temperature, it will not show the slightest gain or loss.

Thus far, the lathe tools, surgeons' scaples, and dental instruments are the only forms of stellite which have been placed on the market. It is hoped, however, that other articles will soon be forthcoming. Among these will be table and pocket cutlery.

Table knives made of alloy have been in use for a period of six years, and show not the slightest tarnish. In fact, they retain their original flash and brilliance far better than any known alloy. The wear on these knives is remarkably slow. A teaspoon which was weighed before and after six months' use showed no weighable loss whatsoever. At the rate of wear after one year's service it seems certain that the spoon will last at least a thousand years and still be serviceable.

Effect of Acids and Alkalis

All of the alloys are attacked by sulphuric, hydrochloric and hydrofluoric acids or by mixtures of the same. They are also attacked by the fused alkalis. As already stated, they change color at a dull red heat, but after once becoming coated with oxide, they undergo no further change and may be maintained for days at 1000° C. without loss or gain in weight. They are practically immune to all organic acids in solution, as well as to all antiseptic solutions, including bichloride of mercury, phosphoric acid, etc. They are likewise unaffected by solutions of the caustic alkalis, and are practically immune to nearly all neutral chemical solutions, including ammonium chloride, which so readily attacks iron and steel.

Table-knife blades made of the alloy remain brilliant and untarnished after years of service. The cutting edge of the table knife wears very well indeed, and from the experience already gained, a set of stellite knives will, if properly taken care of, last at least a generation for ordinary service.

The elastic limit of hammered stellite is not equal to that of tempered steel, but it sufficient for all ordinary requirements. In stiffness it is superior to steel and in fact, to any other alloy or combination in practical use. Table-knife blades can therefore be made quite thin and still be stiff enough for practical purposes.

Kokomo, Ind.

Spanish Pyrites in Restricted List.—Pyrites are included in the list of articles that cannot be imported, except a tonnage not exceeding 125,000 long tons, prior to October 1, 1918. A meeting of the domestic pyrites producers was held in the Council of National Defense Building, Washington, March 11. In order to help out the shipping situation, it was announced that the estimated imports for the next six months would have to be reduced; and the committee appointed to consider this matter recommended that the reduction in imports be made gradually, as follows: April, 40,000 tons; May, 30,000 tons; June, 20,000 tons; July, 15,000 tons; Aug., 10,000 tone; Sept., 10,000 tons. The importance of making up this loss in Spanish pyrites by the increased production of domestic pyrites to the greatest extent possible is made obvious by the above. It is understood that licenses for importing Spanish pyrites loaded after Apr. 15 will be issued only on new applications, in connection with the 125,000 tons of Spanish pyrites allowed for importation between that date and Oct. 1, 1918.

Some Problems in Evaporation and Drying*

By P. B. Sadtler and F. M. de Beers

In our work of designing and building evaporators for all kinds of service we are often presented with new operating conditions, new results desired and new chemical engineering problems that are extremely interesting. While we recognize the necessity and importance of a thorough training and knowledge of the theoretical side of this business, we have also been shown that the important thing, so far as the satisfaction of our clients and the advancement of the chemical industry are concerned, is the practical application of these theories usually based upon some previous experience that we have analyzed as far as possible on the basis of these theories.

It often happens that a process will be marked out in a laboratory and the evaporation part of the process will appear to be very definite as regards certain important features, but our analysis of the result will introduce factors that never appeared at all in the laboratory. For example, we had a client who wanted to concentrate a certain solution beyond the saturation point of the salt contained in the same, with the intention of precipitating that salt in the evaporator. The solution was concentrated on a fairly large scale in the laboratory, and the crystals were perfect in form and rather large, somewhat larger than dairy salt, for example.

Our analysis of the problem from a rather practical standpoint led us to believe that, under actual operating conditions on a large scale, the crystals formed would be very small. This was not because all crystals formed in the particular type of evaporator we intended to use are small, as in most cases the crystals are well formed and of a size much larger than we said would be the case with our customer's product. Our reasons for saying the crystals would be small were as follows: The solution itself and the mother liquor, as the crystallization began, were both easy boiling solutions, practically as fluid as water, with no viscosity, and very few impurities present. The specific gravity while high did not give a liquor having the physical qualities of sugar solutions, caustic soda, etc. The salt formed was very heavy. The circulation in the type of equipment used is very rapid. We reasoned that there would be no chance for the crystal to build up, because of the rapid circulation and the molecular weight of the salt formed. The circulation would remove it from the heating or concentrating zone quickly. The solution being very fluid would not tend to keep the crystals in suspension and the tendency to quickly settle out was, of course, assisted by the high molecular weight of the salt itself. In this way the small crystals would separate from the solution circulating through the tubes and there would be no chance of their becoming larger. With a viscous solution and where the salt formed is not very heavy, the crystals stay in suspension until they are large enough to overcome these factors, when they settle out, notwithstanding the rapid circulation. While they are still small, they remain in suspension and are carried through the heating tube repeatedly and build up because of evaporation produced, and become larger with each passage through the tubes, until they are large enough to overcome the effect of viscosity and circulation when they settle out of the path of circulation. This is the case where sodium chloride crystallizes out of a caustic soda solution, or from a glycerine solution.

Referring back to the problem of our clients, we reasoned that the crystal first formed would not be circulated again, and consequently would be small, and we designed our equipment accordingly. Most any form of salt separator can be used where the crystals are large, but with very small crystals many of the more efficient types of separators or filters have to be discarded.

The filters we put in were not as efficient as other types we make, which are suitable for large crystals, but we believed they were the only style to use if small crystals resulted. Fortunately for us our conclusions were correct, as the crystals were exceptionally small—nearly as fine as talcum powder, and if we had followed the laboratory data alone, and used a filter suitable for large crystals, our client would have had no end of trouble, and he probably would have condemned the entire evaporating apparatus.

This is simply an illustration of the value of applying scientific data to any design of evaporator, and the necessity of occasionally disregarding a more efficient type of construction in order to have an equipment that will be commercially satisfactory.

We often have to advise against the use of multiple effect economy, or to limit the number of effects because of certain physical properties of the solution being concentrated or because of the chemical characteristics of materials in solution or suspension. We know, for example, that a certain minimum effective temperature difference is necessary for efficient operation. The capacity in pounds of water evaporated per square foot per hour is directly proportional to this effective temperature difference, which is the difference between the temperature of the vapor or steam being condenssd and the temperature of the vapor formed from the liquid being concentrated—minus the excess boiling temperature of the solution. The capacity is also proportional to the velocity of the vapor on one side of the tube and to the velocity of the solution on the other side.

In most types of evaporators the velocity of the solution is caused by the heating or evaporating of same and the greater the temperature difference the greater the velocity of the solution. In this way the capacity of a tube is greatly reduced, as the temperature difference goes down and the first cost of the evaporator becomes prohibitive, notwithstanding the apparent saving in steam because of the greater number of effects. As the temperature difference and velocity of circulation are reduced, there may be an opportunity for materials to come out of suspension or solution and deposit on the tube, which would not form there if the circulation were better. Any solution that has a tendency to foam will give less trouble with a greater temperature difference per effect, and this may limit the number of effects we can use, although we have found a way to overcome this trouble to a large extent by following a certain scheme of operation. Where a solution has a boiling point above that of water we must have an effective temperature difference above this excess or we will not do any work. This matter of excess boiling

*Abstract of a paper presented at the St. Louis meeting of the American Institute of Chemical Engineers, December, 1917

temperature often limits the number of effects we can economically use from a commercial standpoint.

It is evident, therefore, that any recommendations we make as to type, number of effects, auxiliaries, etc., must be first based on a complete knowledge of the chemical and physical properties of the solution to be concentrated. We must have the complete confidence of our client, otherwise our work can only be half done. We also believe in explaining our own reasons for every step in the development of the final design, which include reasons based entirely on practical experience with some similar material. I would like to explain in detail some of the problems we have worked out, but in all fairness to our clients I do not feel privileged to refer to specific problems.

The results of our work in every case belong to our client, and no one but that client should know what he is doing.

While we have a large amount of practical data, and while there are a few excellent books on the theoretical side of evaporator design, we have often wanted some conclusive evidence in connection with the determination of certain constants and variables that does not seem to be available anywhere. I am pleased to take this opportunity of announcing that an arrangement has been made between our company and the University of Michigan, whereby we are giving a laboratory to the University, which will co-operate with us in securing fundamental scientific data relating to evaporators. Dean Cooley and Professor Badger, as well as the President of University and the Board of Regents, have co-operated with us to the fullest exent, and within a short time we expect to have some of these factors definitely determined which we now base entirely on practical experience backed by scientific reasoning. All data obtained that is of interest to the scientific world in general will, of course, be published. The establishment of this laboratory should be most valuable to students in chemical engineering, as the first purpose of same is for the benefit of the students, and our own work will only be done when the laboratory is not needed for the student work. The laboratory is housed in the old boiler house of the University, located in the southeast corner of the campus. It occupies half of the building, the evaporators themselves being erected in the boiler room.

This laboratory will be used to work out government problems, also commercial problems of responsible individuals or companies. The main purpose of the plant from our standpoint, however, is to give us a place where we have all the equipment and facilities for the determination of evaporation factors, with all variables eliminated except the one we are working on. We wish to correlate theoretical and practical data and do not intend to repeat the work done by such eminent authorities as Dr. Hausbrand, for example. We intend to use to the fullest extent the results of his work and may later check up certain things, largely to gain the knowledge that is only possible through such experiments. Our equipment is large enough to carry on our experiments on a commercial scale, with the personal error factor very largely eliminated because of the quantities handled. We want our results to be commercially valuable, and among the things we are going to do are the following:

Determination of velocities of steam, vapor and liquor in various standard types of evaporators and under various normal operating conditions.
Value of catchalls of various types.
Amount of loss of liquor by entrainment and by foaming and best means of overcoming same.
Separation of crystals from mother liquor.
Location of non-condensible gases and amount of same from various commercial solutions, also source of same and best means for their removal.
Determination of loss of vapor with efficient removal of these gases.
Determination of volume removed at various stages of the work in a multiple effect, etc.
Conductivity factors in heaters and surface condensers under varying conditions as to velocity, viscosity, size and shape of tube, etc.
Constants based on work done per square foot of heating surface with the following variables:
Effect of velocity of steam or vapor.
Effect of velocity of liquor.
Effect of temperature difference.
Effect of vapor density.
Effect of crystallization.
Effect of scale on tubes.
Effect of temperature of entering liquor.
Effect of materials in suspension.
Effect of materials in solution.
Effect of excess boiling temperature.
Effect of viscosity.
Effect of evaporate type.
Effect of density of liquor.
Effect of tube length and diameter.
Effect of tube depth in a horizontal tube machine.
Effect of downtake area and location of same.
Effect of metal used for heating surface.
Effect of surface of tube on capacity.
Effect of protective coverings.
Effect of moisture in steam.
Effect of hydrostatic head.
Effect of area of liberating surface, etc., etc.
Liquor level regulators and their usefulness.
Determination of effect of heat of solution when concentrating a salt solution.
Best method of regulating size of crystal formed.

These are only some of the things we have planned to do, but this may give you an idea of how the laboratory will be used. We feel we just about know a lot of these things, but want this conclusive confirmation or correction of our own theories, which are now largely substantiated by actual results. We would be very pleased to receive suggestions from members of the Institute as to data that should be obtained as regards general or specific evaporation problems. We expect later to expand the laboratory so it will include drying machinery, filtering and pressing equipment, etc. While we are called upon to work out a good many chemical engineering problems that do not relate to our evaporators, the purposse of this laboratory for the present, at least, is simply to secure evaporation data during such time as it is not needed for student work.

Swenson Evaporator Co.,
Chicago, Ill.

Portugal Takes Over Mines During War.—According to Consul General W. L. Lowrie, Lisbon, a decree of the Portuguese Government dated March 14 reserves to it the sole sale and export of all minerals found in the country that are of value in war industries. The Government, through the Minister of Labor, upon recommendation of the Department of Mines, will fix the prices at which the minerals affected by the decree will be sold. Wolfram and chromium are included in the provisions of the decree, and consequently all exportation of these minerals is prohibited. All stocks at the mines or elsewhere must be declared to the Department of Mines under penalty that the mineral will be seized.

Synopsis of Recent Metallurgical and Chemical Literature

Aromatic Nitriles by Catalytic Dehydration.—A new method of preparation of aromatic nitriles in the vapor phase has recently been described by ALPHONSE MAILHE in *Comptes-Rendus, de l'Académie des Sciences*, Jan. 7, 1918, vol. 166, pp. 36-38.

It is known that on treating esters by ammonia, these are converted into amides:

$$R.CO.OR' + NH_3 = R.CONH_2 + R'OH.$$

on the other hand, amides yield nitriles by dehydration in the liquid phase in the presence of phosphoric anhydride or certain catalysts (pumice, sand, alumina, graphite).

$$RCONH_2 = H_2O + RCN.$$

Amides, however, are solid substances with high boiling points and, consequently, difficult to pass over catalysts in the form of vapor. The question arose whether the action of gaseous ammonia (NH_3), reacting with esters in the vapor phase in the presence of dehydrating catalysts, could not give the two reactions given above simultaneously and, thus, lead directly to nitriles. This assumption has proved to be correct and has been substantiated by experiments.

On directing methyl benzoate ($C_6H_5.CO_2.CH_3$) vapors together with gaseous NH_3 over thoria heated between 450-470 deg. C., a gas is collected consisting of excess NH_3 and H_2, and a liquid which separates into two layers: the one, aqueous, giving an aldehydic reaction; the other, on being subjected to distillation, yields a small quantity of CH_3OH with a little CH_2O held in solution therein, and another fraction which distills between 181-191 deg. C. Above 191 deg. C. the residue left was insignificant in amount. The portion boiling between 188 and 191 deg. C. possesses a strong odor of bitter almonds. With chloride in hydrochloric acid solution, it gives immediately a crystalline yellow precipitate, pointing to the presence of benzonitrile $C_6H_5.CN$ which boils at 190-191 deg. It has been identified by subjecting it to hydrogenation over reduced nickel at 180-200 deg. C. whereby it is converted into $C_6H_5.CH_2$ and a mixture of benzylamine and dibenzylamine.

As regards the aldehydic reaction pointed out above, it is due to the decomposition of a small amount of methyl alcohol into H_2 and formaldehyde:

$$CH_3OH = H_2 + H.COH.$$

It will be seen that the simple decomposition of methyl benzoate by gaseous NH_3 in presence of thoria, constitutes an easy method for the production of benzonitrile.

$$C_6H_5CO.OCH_3 + NH_3 = C_6H_5.CN + H_2O + CH_3OH$$

Up to 400 deg. C. this reaction does not take place in an appreciable manner. At about 430-440 deg. C., it is becoming important and, at 470-480 deg. C. it is almost total.

In the case of ethyl benzoate the reaction leads also to benzonitrile.

Toluidic esters behave similarly to benzoic esters, yielding the corresponding toluidic nitriles:

$$C_6H_4\begin{matrix}CH_3\\CO.OR\end{matrix} + NH_3 = C_6H_4\begin{matrix}CH_3\\CN\end{matrix} + H_2O + ROH$$

The methyl-ester of ortho-toluidic acid which boils at 207 to 208 deg. C. yields ortho-tolunitrile which boils at 203 deg. C. The ethyl ester of paratoluidic acid leads likewise to paratolunitrile. Phenylacetic acid readily gives ethyl phenylacetate and the latter, when passed in the form of vapors together with NH_3 over thoria at 450- to 460 deg. C. yields benzyl cynide $C_6H_5CH_2CN$. By this method which seems to be possessed of a very general character, the use of potassium cyanide is eliminated. The yields of aryl nitriles are said to be good.

Dimethylaniline by Catalytic Dehydration.—A new method of preparation of mono-methyl-aniline and dimethylaniline was presented to the French Academy of Sciences by A. Mailhe and F. de Godon and published in *Comptes-Rendus*, 1918, March 18, vol. 166, pp. 476-469.

It is known that dimethylaniline is an intermediate used in the production of a large number of artificial "coal-tar" dyes. Monomethylaniline is less used for this purpose. In modern industrial practice for the preparation of these two bases, aniline is alkylated by means of methanol. $C_6H_5NH_2$ and CH_3OH are heated together with HCl or H_2SO_4 in autoclaves at 180 deg. C. in the case of monomethyl-aniline, and 230-235 deg. in that of dimethyl-aniline, with increase of pressure to 30-35 atmospheres. Upon termination of the reaction, the reaction mixture in the autoclave is blown out by means of compressed air into a kettle containing caustic soda in order to liberate the base which is driven out by means of steam. This operation is then followed by rectification. By noting also that the mixture of CH_3OH and H_2SO_4 must be prepared in advance, prior to the reaction proper, under special conditions and that the operations of charging and heating the reaction vessels require certain precautions, it will be seen that the "technique" of this reaction is rather complicated.

The reactions of formation of these two secondary and tertiary bases from CH_3OH and $C_6H_5NH_2$ may be considered as dehydration reactions:

$$C_6H_5NH_2 + CH_3OH = C_6H_5NHCH_3 + H_2O.$$
$$C_6H_5NH_2 + 2CH_3OH = C_6H_5N(CH_3)_2 + H_2O$$

The hypothetical consideration that, on subjecting a mixture of aniline and methyl alcohol in the vapor phase to the action of a dehydrating metallic oxide at a suitable temperature and, thus, to make the reaction proceed in the sense indicated by the above equations, has been given substantial proof by experiment.

On directing a mixture of aniline vapors and methyl alcohol vapor over thoria heated between 400 and 450 deg. C., a notable proportion of mono- and dimethyl-aniline has been obtained. But part of the $C_6H_5NH_2$ had not been acted upon.

Zirconia, ZrO_2, displayed a behavior almost analogous to that of ThO_2.

Alumina, Al_2O_3, seems to be best adapted for effecting this preparation of the secondary and tertiary bases. On directing over this catalyst a mixture of aniline and a slight excess of methyl alcohol (both in the state of vapor), at once a mixture of monomethyl- and dimethyl-aniline has been obtained with only insignificant traces of the original aniline. In this reaction a small amount of methanol is destroyed by dehydration with secondary formation of methyl ether.

$$\begin{matrix} CH_3\overline{|OH} \\ CH_3\underline{|H} \end{matrix} \longrightarrow \begin{matrix} CH_3 \\ CH_3 \end{matrix} > O + H_2O$$

The excess of alcohol is condensed with the bases and can be recuperated by rectification of the condensate. When conversion of the aniline-alcohol is complete, the water and alcohol are separated from the free bases by decantation which latter are then subjected to distillation. In this manner a mixture of monomethylated and dimethylated aniline is obtained.

It was of importance to verify whether methylation of monomethyl-aniline could be carried so as to convert it totally into the dimethyl-derivative. For this purpose a mixture of monomethyl-aniline and methyl alcohol was directed in the state of vapor over Al_2O_3 heated to 400 to 500 deg. C. The secondary base was converted into tertiary base.

In these operations the alumina assumes after a certain time a yellowish coloration which later darkens to a brownish tint. Its catalytic power is slightly diminished. A simple calcination is sufficient to make it reassume its pure white color as well as its original activity.

The extreme simplicity of the preparation of these two important bases is evident. The manipulations of the raw materials are reduced to a minimum and no longer require the application of high pressures and acids which had a strong corroding effect upon the cast-iron autoclaves. It is true that this inconveniency has since been avoided by using cast-steel autoclaves lined with an acid-proof enamel. Besides, the use of compressed air, sulphuric acid and caustic soda and the driving-out by steam are steps no longer required. Whereas in present-day manufacture aniline must be very pure and contain not more than 0.5 per cent of H_2O, the alcohol be free from acetone which, owing to its high volatility, subjects the autoclaves to excessive interior pressures, in the new method the aniline may contain a certain proportion of water without detriment to the yield of the reaction, and the presence of a rather great proportion of $(CH_3)_2CO$ in the alcohol entails no inconveniences.

Size of Metallic Crystals.—Dr. G. H. Gulliver presented a note on grain size before the March meeting of the Institute of Metals (British) in which he observed that there is a fairly widespread belief on insufficient evidence that under favorable conditions the crystal grains in a metallic mass approximate to a uniform size and uniform compact shape. However, a cursory examination of a micrograph shows that there is a large variation in the size of the grain sections—too large, in fact, for the satisfactory employment of a mean if the sections were disconnected quantities, which, of course, they are not. Therefore the real significance of the term "grain size" is "mean granular volume." Dr. Gulliver presents a mathematical treatment of the subject, confining his attention to the relation between the mean volume of a grain and its mean area of section, when the material shows only one kind of structural constituent. With grains of approximately equal volume (varying say plus or minus 10 per cent), and approximately the same compact shape (that is to say, being polyhedrons of from ten to sixteen faces, with a variation of plus or minus 5 per cent among the corresponding diameters), a micrograph containing at least 200 crystalline sections would show a nearly constant number of grain sections, from whatever part of the mass it is obtained. The approximate relation of the two-dimensional grain size to the mean granular volume is shown by the following equation:

$$\text{Average granular volume} = \frac{3}{2}\left(\frac{A}{n}\right)^3$$

where A is the cross-sectional area of the section under examination, and n is the mean number of grains appearing in that section. Thus the fraction A/n is the area usually called "grain size." As before noted, if the grains are approximately equal and equi-axed, random sections yield a nearly constant grain size. The converse of this statement is not necessarily true, and a constant two-dimensional grain size might only indicate a recurrent form of distribution. A ready means of detecting a gross departure from uniformity is to measure the areas of the grains of a suitable micrograph, and compare the maximum with the mean. The maximum value of this ratio for equi-axed crystals is shown to be 1.7 with a probable plus or minus variation of 20 per cent—roughly, to lie between 1.5 and 2.0. These ratios may usefully be employed as a criterion of uniformity of the grains, and its value in several measured photographs has been found to lie between 3.5 and 5.0, the higher values being obtained after longer periods of annealing. In other words, the grain size was far from uniform, and annealing increased the degree of non-uniformity.

Manufacture of Crude Sodium Manganate.—The *Journal of the Chemical, Metallurgical and Mining Society of South Africa* contains a short description of this subject by F. Wartenweiler. A laboratory process was worked up in view of the shortage of easily soluble oxidizers for use in the reduction works of the Rand and crude sodium manganate was found to be an acceptable substitute for the nearly pure potassium permanganate formerly used. The reactions used are either

$$3MnO_2 + 2NaOH = Na_2MnO_4 + Mn_2O_3 + H_2O$$

or

$$2KNO_3 + 2MnO_2 + 4NaOH = 2Na_2MnO_4 + 2KNO_2 + 2H_2O$$

Ferruginous manganese dioxide ore (pyrolusite) from Pretoria furnished the manganese and analyzed about 40 per cent Mn. Commercial caustic soda and potassium nitrate were also used. The combination found most effective in the first equation was 1 part by weight of the 40 per cent manganese ore to 1.44 parts caustic, and 1 part of ore 1.1 part caustic and 0.4 parts nitre for the second. It is necessary to use a large excess over the theoretical requirement of caustic soda; anything less than 110 per cent will give no manganate. The work was carried on in a four-hearth brick muffle-type calcining furnace ordinarily used for calcining acid treated zinc-gold precipitate. No particular difficulty is encountered in producing the material in large quantity. A product containing 28 per cent sodium manganate was made by the first equation as follows: The ore was finely ground in a ball mill and the chemicals well

mixed in 500-pound batches before charging into each one of the four hearths, where the quantity formed a layer about six inches deep. No stirring or rabbling is necessary. The furnace was heated to about 450 deg. C. prior to charging, when the temperature was gradually raised to about 560 deg. C., maintaining this heat for eight hours. The furnace is cooled for four hours before the charge is withdrawn. By the end of the heat the mass has agglomerated into a sticky mass which must be barred loose. As the manganate is slowly and gradually converted on exposure to air to sodium permanganate, manganese carbonate and manganese dioxide, it must be packed in sealed packages. The crude mass, upon coarse crushing, is more soluble than bleaching powder, and is easier to handle and control. When once dissolved and converted to permanganate by dilution with water, it is comparatively stable.

New Chimney at Tacoma Smelting Company.—The new stack of the Tacoma Smelting Company at Tacoma, Washington, 571 ft. by 23 ft. 11 in., exceeds by one foot the height of the tallest stack previously in existence—the concrete chimney at Saganoseki, Japan. This new chimney was built as a result of the smoke investigations conducted by the American Smelting and Refining Company (see METALLURGICAL AND CHEMICAL ENGINEERING, Vol. XVII, page 682, Dec. 15, 1917), and supplanted a thirteen-year old concrete chimney, 300 ft. by 21 ft. CHARLES E. FOWLER discusses the foundation problems encountered in the construction in *Engineering News-Record*, Vol. 80, page 644 (April 4, 1918). The first foundation excavation was carried about 8 feet below the original surface to a bed of compact sand, but water was encountered in a test pit at a depth of four feet further. Further test pits revealed a strata of hard blue clay lying at from 9 to 30 feet below the first footing. The foundation area was therefore isolated by the construction of long cut-off walls from the surface to this hardpan. As to the foundation itself, three courses were open: First, to risk the uneven settlement on the varying thickness of sand after its drainage; second, to drive concrete piles to the hardpan, or, third, to carry the foundation itself to the hardpan. The third course was adopted, and a reinforced base, as shown in Fig. 1, was designed by R. Bergerson, chief engineer of the Smelting company. The final dimensions of the work are also given in the figure. Throughout the height there is a 4-in. firebrick sectional lining, separated from the shell by a 2-in. air space. A wind velocity of 125 miles an hour, producing a pressure of 78 lb. per sq.ft. in a flat surface was used in the stability calculations. Six-tenths of the projected area of the circular shaft was taken as the effective normal surface. Permissible soil pressure was determined by the formula

$$p = 0.68\ a + 0.014\ ah$$

where a equals 3 tons per square foot for moist sand, of 5 tons of hard clay; h is the depth of the foundation bed in feet, and p is the allowable soil pressure in tons per square foot. The computed maximum base pressure from the assumed wind in combination with the weight of the stack is 5.01 tons per square foot.

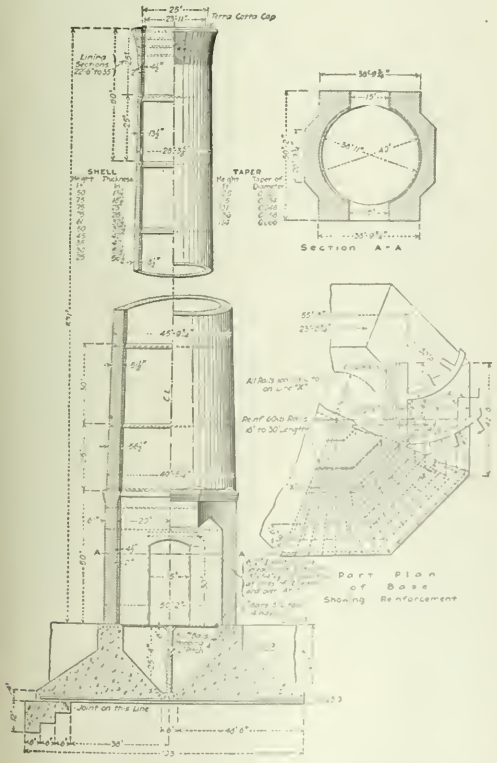

FIG. 1. BASE AND SHELL DETAILS OF TACOMA STACK

Potash from Coal-Burning Blast Furnaces.—Prof. R. A. BERRY and D. N. MCARTHUR present the result of their studies on the question of recovering potash from the coal-burning iron blast furnaces in Scotland, before a joint meeting of the West of Scotland Iron and Steel Institute, and the Society of Chemical Industry. The work is compared with that of Wysor (see METALLURGICAL AND CHEMICAL ENGINEERING, Vol. XVI, page 205, Feb. 15, 1917), and attention called to the fact that the recovery in Scotland is a considerably different problem from that existing in the United States, since the potash content of the ores is not only lower, but coal is used as a fuel in place of coke, which produces a gas heavily laden with tarry matters. Most of the heavy tarry matter is separated in condensers, and in settling carries down considerable dust. The rest of the tarry matter, the ammonia, and most of the remaining fine dust are then caught by the water during the cleaning of the gas in the scrubbers. The spent liquor from the scrubbers, from which the bulk of the tarry matter and the ammonia have been extracted, is usually allowed to waste, although one plant for several years has recovered potassium salts from this by evaporation. On account of the relatively small amount of dust produced, the authors judge the treatment of this liquor to be at present the most likely means of regaining potash. Eight samples of flue dust from coal-fired furnaces were received, containing an average of 8.86 per cent water soluble potash. The total

yearly yield of flue dust from these plants, however, is only 71 tons. These samples of stove dust were analyzed. The yield of this material from coal-fired furnaces is negligible. However, coke-fired furnaces should yield 150 tons of material containing 7.6 per cent of water soluble potash. Samples of tube cleanings from 15 works were received, and while the potash content ranges from only 1 to 2.7 per cent, nearly 15,000 tons of the material is collected yearly. Fifteen works supplied samples of spent liquor which averaged a residue containing 33.5 per cent potash. The authors calculate that 1694 tons of residue could be collected yearly. Owing to the presence of the tarry matter in this liquor, evaporation is retarded, and is a difficult operation, but when the yield of residue amounts to 100 tons per annum, and exhaust steam for evaporation is available, the matter of its recovery is worthy of serious consideration. An evaporating plant would cost about one dollar per gallon daily evaporation; with spare heat the investment would be recovered in a few years, and even if the value of the potash recovered would but pay for the expense, this method would be the best for its disposal. The "pitch" recovered from the gases amounts to about 112 lb. per ton of coal burned, and contains an average of 15 per cent solids, which in turn will analyze 8.8 per cent potash. The burning might be difficult, but probably could be accomplished. A balance computed for one of the co-operating plants showed as follows:

Potash charged into furnace per ton of pig produced		7.6 lb.
Recovered in spent liquor	1.4 lb.	
Recovered in flue and stove dust	0.04	
Recovered in pitch	1.7	
Recovered in tube cleanings	0.2	
Lost in slag	2.7	
Total accounted for	6.04	6.04
Unaccounted for		1.6 lb.

The total quantity of potash recoverable from the potash-bearing by-products from Scottish blast furnaces (12 companies, including 17 works and 102 furnaces) is as follows:

1,694 tons spent liquor residue @ 33.5%	567.4 tons K_2O
100 tons flue dust at 8%	8.0
11,092 tons pitch ash @ 8%	885.8
8,250 tons tube cleaning dust @ 2.5%	206.0
Total possible	1,667.2 tons K_2O

Motor Oils from Lignite.—Investigations recently completed in the *K. W. Institut für Kohlen-forschung*, and mentioned in *Rivista Tecnica d'Elettricita*, Feb. 14, 1918, have shown some remarkable results. Braunkohle and similar lignites were treated with diluted sulphuric acid at ordinary temperatures and a viscous mineral oil of golden-yellow color was obtained, amounting in weight to 5 per cent of the coal. If this oil is treated with naphthaline at higher temperatures, in the presence of chloride of aluminum, an oil is obtained which fulfils the same duties as kerosene. By treating lignites with ozone, carbon compounds are obtained which are soluble in water. It is not possible at this time to judge the true and farreaching chemical importance of these discoveries, says the Italian magazine, which seem to produce fatty substances from lignite.

Carbonization of Illinois Coals.—In Bulletin 20, Co-operative Coal Mining Series, Illinois State Geological Survey, F. K. Ovitz of the U. S. Bureau of Mines gives the results of experiments on the carbonization of Illinois coals in inclined gas retorts. The summary of results and conclusions follows: Illinois coal mixed with Kentucky coal before charging yields better coke than Illinois coal alone. The coke has a more uniform cell structure, is denser, more homogeneous, and stronger. If all the retorts are charged with the same mixture, uniform operating conditions can be maintained to insure proper carbonization of all the charges. If, however, the coals are used unmixed, the charges of Illinois coal require either a higher temperature or a longer period of carbonization than the charges of Kentucky coal. Coke from Illinois coal alone contained more ash and had more tendency to form clinker than coke from a mixture of Illinois coal and Kentucky coal. The Kentucky coal had a low ash content, and the ash had a high softening temperature; consequently the ash content of the coke from the mixture was decreased, and the softening temperature of the ash was raised. The yield of coke from mixtures was larger than from Illinois coal alone, and increased as the percentage of Kentucky coal was increased. The amount of breeze in the coke made from unmixed Illinois coal was greater than in coke from mixtures. The amount of breeze from mixtures decreased as the amount of Kentucky coal in the mixture was increased. Mixtures gave higher gas yields and consequently enabled greater production of gas with a given equipment than could be obtained from Illinois coal alone. There is a considerable supply of Illinois coal with a sulphur content low enough to permit its use for gas making without operating trouble from sulphur. The more general use of Illinois coal in gas plants deserves careful consideration from gas manufacturers. At many plants in the Central West the cost of producing the gas can be considerably reduced by using either Illinois coal alone or by mixing with it another coal.

Alternating Current Electrolysis.—Experiments on this subject are described in the *Journal of Physical Chemistry*, for February, 1918, by Harry B. Weiser. The results of the investigation are summarized by the author as follows:

The efficiency of the electrolytic corrosion of solid metallic electrodes with the alternating current varies so widely with minor differences in the electrode surface that the results of a given set of experiments cannot be reproduced.

The mercury electrode in thiosulphate solution under the influence of the 60 cycle alternating current is reproducible.

The effect of widely varying conditions on the efficiency of electrolytic corrosion with the alternating current of constant frequency has been studied with mercury electrodes in sodium thiosulphate solution.

The efficiency of corrosion increases almost directly as the concentration of thiosulphate solution. With too high a concentration, however, a film of sulphide forms over the electrode which cuts down the corrosion.

The efficiency of corrosion increases with the current density but not in direct proportion. The variation from strict proportionality is greater in dilute than in concentrated solution.

Mechanical stirring increases the efficiency of corrosion.

The efficiency of corrosion decreases with decrease in temperature.

Any variation in conditions that affects the concentration of electrolyte in the immediate region of the electrodes correspondingly affects the efficiency of corrosion.

Under like conditions zinc electrodes corrode much less readily with the alternating current than do mercury electrodes.

The effect on the efficiency produced by variations in current density, stirring, temperature and concentration of thiosulphate solution is of the same character with solid metallic electrodes as with mercury; but with the former these effects are negligibly small compared with that resulting from slight differences in the electrode surface.

Recent Metallurgical and Chemical Patents

Zinc and Lead

Details of the Electrolytic Zinc Process.—A series of patents have been issued to FREDERICK LAIST and J. O. ELTON of Anaconda, Mont., (assigned to the Anaconda Copper Mining Co.) on certain features of the electrolytic production of zinc.

In order to clear the electrolyte of arsenic and antimony the precipitation of an excess of ferric hydroxide by lime or otherwise is necessary. This carries down nearly all of these elements, probably as ferric arsenate and antimonate. More iron may be required than is dissolved from the leached ore, and while this deficiency may be gained by passing the solution over iron-bearing material, this method is very slow, and the inventors prefer to supply it as follows: Scrap iron or iron ore is heated with 20 per cent sulphuric acid until the solution contains 5 per cent or more iron, when manganese dioxide or any oxidized ore of manganese is added to the hot acid solution, quickly bringing all iron to the ferric condition. A sufficient quantity of this ferric solution is then added to each leach, the iron, with the arsenic and antimony, is precipitated and removed. The manganous salts may be reoxidized in the electrolytic operation and are available for re-use. (1,255,436, Feb. 5, 1918.)

Instead of adding the ferric precipitate (containing a very material quantity of zinc sulphite) to the unroasted ore and subjecting it to a high temperature calcination which not only oxidizes the iron to an insoluble state, which is desirable, but also destroys any sulphates present with the accompanying waste of sulphuric acid, the latter may be avoided by roasting the precipitate in a separate furnace with temperature controlled and less than 625 deg. C. (1,255,438, Feb. 5, 1918.)

Or this precipitate and all other residues containing all the copper, lead, silver, gold and also a material percentage of the zinc of the original ore may be dried, mixed with fine coal, and smelted in a reverberatory furnace. There will result a matte containing most of the copper, silver and gold, a fume consisting principally of oxide of lead and zinc, and a slag which is reasonably free of values. The fume is collected in a bag house or otherwise, and is returned to the leaching plant where it is treated with dilute sulphuric acid. The zinc sulphate solution produced is treated as other like solutions, and the residue containing most of the lead of the original ore may be dried and smelted

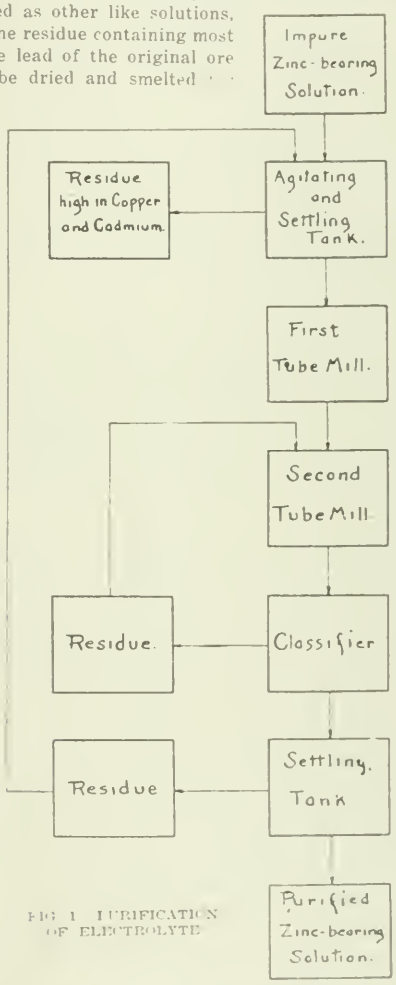

FIG. 1. PURIFICATION OF ELECTROLYTE

lead in the usual manner. (1,255,440, Feb. 5, 1918.)

Since the precipitation of impurities in the electrolyte ordinarily requires a large excess of zinc, while tube mills with zinc balls necessitate a very slow rate of flow, the inventors patent the process shown in the flow sheet, Fig. 1, wherein the bulk of the copper, cadmium and other electro-negative metals are first precipitated by zinc dust. The clear solution then goes to a pair of tube mills, the first with zinc balls, the second with zinc shot. Thus the purification is effected at a higher rater of speed. (1,255,434, Feb. 5, 1918.)

They further patent another method of purifying solutions of traces of copper and cadmium by the use

of zinc sponge which is more efficient than furnace metal. This sponge is prepared by the electrolytic precipitation from the cold, neutralized, impure solution itself at voltages between 0.5 and 2.3, and current densities between 2 and 30 amp. per sq.cm. Zinc anodes are used, maintaining normal concentrations of the metal. At lower voltages the sponge tends to collect on the bottom of the cell, but it may effectively remain suspended in the solution or attached to the cathode. If the rate of flow of the solution is slow its complete purification may be effected during the passage and the sponge may be available for other portions. A more rapid rate is desirable, so that the overflow carries sufficient sponge to complete its own purification. If the current conditions are properly regulated, little or no zinc is precipiated, the deposit consisting of the more electro-negative impurities. If care is taken to dry the sponge under strictly non-oxidizing conditions it may be used in place of the ordinary zinc dust at a later time. (1,255,435, Feb. 5, 1918.)

The formation of the zinc sponge may advantageously follow a primary purification by metallic zinc, when residual traces of arsenic are eliminated as arsine. For deposition of the purified solution into coherent cathodes, the conditions should preferably be: acidity of 4.5 per cent, temperature of 35 deg. C., voltage from 3 to 4, current density 0.0215 to 0.0323 amperes per square centimeter. (1,255,439, Feb. 5, 1918.)

Difficulty in making a coherent deposit depends not only upon the purity of the electrolyte, but upon the cathode as well, which must be highly electro-positive. Thus, pure aluminium is quite suitable, but aluminium containing 5 per cent of copper will often take no deposit, while 1 to 2 per cent copper will scarcely deposit after it has been stripped a few times. Aluminium bronze may be made to take a good deposit if the alloying metals be removed by nitric acid, and the resulting film of alumina removed. After a few deposits, however, when the pure aluminium surface thus prepared becomes contaminated or worn, a retreatment is necessary. The more electro-negative impurities in the cathode sheet are thought to form couples with the deposited zinc, greatly increasing the rate of solution and therefore cutting down the current efficiency. Laist & Elton therefore patent the use of a pure electro-positive cathode. (1,255,433, Feb. 5, 1918.)

Since the ill effects of a small impurity on the electrodeposition persist for days after the inflowing solution is restored to normal, the inventors equip a test cell with electrodes similar to those employed in the main system, and so place this cell as to receive a continuous portion of the purified solution passing to the storage tanks from which the main electrolytic cells receive their supply. The current and other conditions in this indicator cell being maintained as in the main cells, the quality of the deposit and the current efficiency serve as an accurate indication of the purity of the electrolyte. In case any portion of the solution falls below the standard of purity, this part can be re-purified before entering the main cell room. (1,255,437, Feb. 5, 1918.)

Treatment of Zinc-Lead Fume.—C. C. NITCHIE, of Depue, Ill. (assigned to the New Jersey Zinc Co.), proposes the mixing of zinc-lead fume with sufficient ammonium sulphate to transform all other metallic compounds contained into the corresponding sulphates. The reactions are of the following type:

$$ZnO \times (NH_4)_2SO_4 = ZnSO_4 \times 2NH_3 + H_2O$$

The mixture is heated in a suitable muffle; the reaction commences at about 225 deg. C, and proceeds rapidly at 300 to 350 deg. The escaping ammonia is recovered for reuse. After the reaction the temperature is raised to about 625 deg. C, to expel arsenic and to render iron sulphates insoluble. Water leaching will now produce a residue containing most of the lead, silver, gold, iron, and silica and but little copper and zinc, and can be easily smelted in a lead blast furnace. The solution contains most of the copper and zinc, and but little of the other impurities. It can be purified and electrolysed; or it may be evaporated and the lead-free salt retorted in the usual way. Or finally, it may be precipitated as a basic compound by the addition of ammonium carbonate, with the formation of the corresponding amount of ammonium sulphate for reuse in the early part of the process. (1,258,934, March 12, 1918.)

Zinc Chloride from Zinc-bearing Ores.—FRANK K. CAMERON and others of Salt Lake City, Utah (assigned to American Smelting and Refining Company), patent the process of mixing an oxidized or roasted complex ore with a slight excess of 30 per cent HCl, heating the mixture slowly at first to drive off CO_2 and other gases, then quickly to complete dessication, and finally for a sufficient time at about 300 deg. C. to complete the evolution of acid gas. Thus iron, manganese, aluminium, silicon and magnesium are converted into insoluble oxides, and after lixiviation the solution will carry practically all of the zinc as chloride. It also contains calcium and lead chlorides, which are removed by precipitation with zinc sulphate. Iron and aluminium may be removed by known methods, or the solution purified as noted in the following patent. (1,261,695, April 2, 1918.) As an alternate process, the ore, pulverized to 100 mesh, is mixed dry with sodium or calcium chloride containing sufficient chlorine to combine with the metallic bases. Distillation in an iron retort will volatilize lead, silver and gold chlorides, and transform the zinc into a basic chloride which is retained in the residue. The residue is then leached in hot water acidified with HCl. In case there is much separation of gelatinous silica, evaporation to dryness may be necessary, followed by an additional leaching. The zinc chloride may be precipitated as a solid halide of sodium, potassium or ammonium by adding the desired alkali chloride to the solution. This salt may be further purified by recrystallization, and may be then decomposed with strong hydrochloric acid. (1,261,696, April 2, 1918.)

Production of a Superior Zinc-Lead Pigment.—J. A. SINGMASTER and F. G. BREYER of Palmerton, Pa., (assigned to New Jersey Zinc Co.) have ascertained by an examination of various fractions produced in the process of zinc-burning, that those fractions having a good body or oil absorbing capacity and hiding

power, and which were not overheated, showed a higher ratio of sulphur to lead than similar pigments of a pronounced pink tint. Overheating the pigment substitutes a yellowish tint for the pink, and furthermore granulates the fume. They therefore patent the process and method of burning a zinc-bearing substance in a pigment furnace—such as the blast-furnace type or of the Wetherill grate-furnace type—volatilizing the zinc and lead from the charge, immediately oxidizing the same in a sulphatizing atmosphere, and quickly removing the fume from the region of high temperature. The sulphatizing atmosphere may be obtained by mixing a sufficient quantity of sulphur bearing ores with the oxide, by interrupting the preliminary roasting operation at that point where sufficient sulphur will remain in the calcine, by adding elemental sulphur, or by dropping sulphuric acid into the furnace. The ratio of sulphur to lead oxide necessary to make the improved pigment may lie between one-half and four-thirds, but preferably is about five-sixths. In any case, it is important that the sulphatizing compounds be of such a nature, and be added in such a way that they will furnish the required amount of sulphate throughout the entire evolution of the metal. (1,257,136, Feb. 19, 1918.)

Recovering Zinc from Slags.—HERMAN WITTEBORG of Caldwell, Idaho, patents the arrangement of recovering zinc from slags as follows: He causes the slag to flow through a succession of long, narrow, reverberatory furnaces in a thin sheet, where it is superheated by an oxidizing flame, and possibly stirred by a hot air blast. Lime to substitute as a base, and carbon for reduction purposes, may be added to the slag at the outset. The resulting furnace gases are collected and the metallic oxides condensed and separated. (1,250,261, Dec. 18, 1917.)

Removing Cadmium from Zinc Ores.—CHARLES P. FISKE, of Palmerton, Pa., (assigned to New Jersey Zinc Co.) patents the application of an ordinary Brückner furnace to the method of eliminating cadmium from zinc calcines already covered in Patent No. 1,161,885 (see METALLURGICAL AND CHEMICAL ENGINEERING, Vol. XIV, page 220, Feb. 15, 1916). This process consists of heating the calcine in a reducing atmosphere at temperatures ranging from 700 to 850 deg. C., wherein the cadmium is eliminated. In the later invention the reducing atmosphere is maintained by the admission of producer gas into the fire-box opposite the flue connecting to the roasting cylinder. (1,246,576, Nov. 13, 1917.)

Composition for Retorts.—J. D. HOLLINGSWORTH and JOHN MITCHEM of Kusa, Oklahoma, have discovered that zinc retorts of the following composition have a life of up to sixty days when working on Western ores, as compared to twenty days if made of the ordinary mixtures. They dry-mix 36 lb. of St. Louis fire clay with 59 lb. of fire clay cement (hard burned clay ground to a powder) and 14 lb. of "cc" or "g" grade graphite, and then pug this mixture with a solution containing 25 per cent by weight of common salt. The resulting dough is allowed to stand for 24 hr., then molded to shape in a hydraulic press, and dry-heated at approximately 120 deg. F. for from 15 to 20 days. The dried retort is gradually preheated before use. (1,249,960, Dec. 11, 1917.)

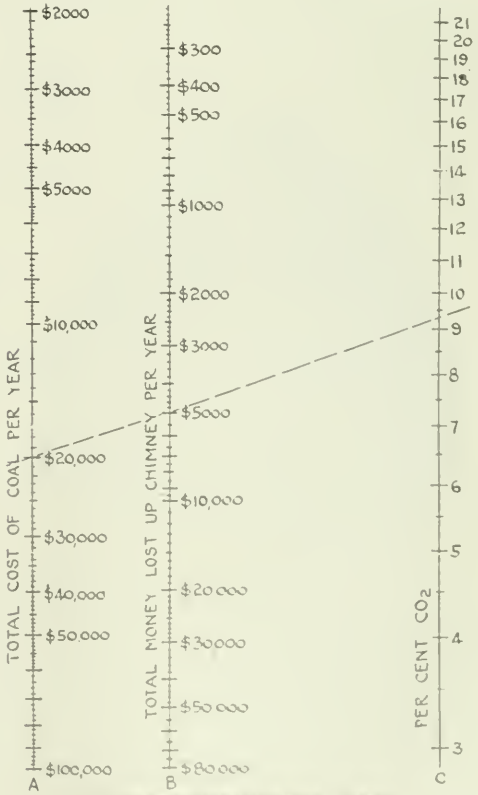
Determining Loss Due to Low Carbon Dioxide

THE accompanying useful chart has been developed by the Uehling Instrument Co., 71 Broadway, New York. It is of unusual interest and value at the present time when the coal problem is so important, for it enables anyone to quickly and closely estimate the money now being lost up almost any chimney due to low CO_2.

Simply connect the percentage of CO_2 (shown in column C) with the money now being spent per year for coal, (shown in column A) and the intersection of the connecting line with column B immediately gives the amount using from the chimney in the form of heated gases.

The object of this chart is to show that a high percentage of CO_2 is most desirable. Even where the CO_2 is as high as 21 per cent, the theoretical maximum there is a loss because in the average power plant the flue gases leaving the boiler have a temperature as high as 500 or 600° F. Loss therefore is inevitable unless a blower is used for exhausting the gases and some sort of interchange system is installed for either heating the feed water or preheating air and leading it under the grate.

It is significant that most of the large power plants



of today have adopted CO_2 instruments that record automatically and continuously. The reason for this is to keep constant tab on the workers in the boiler room and the efficiency of combustion. The recorder may be placed at any convenient distance from the boiler in the office of the chief engineer, owner, manager or superintendent, while an auxiliary CO_2 indicator is placed on the boiler front in full view of the fireman. The function of the indicator is to keep the fireman constantly informed as to the efficiency of his own work. This feature is most commendable.

Coal cannot be saved by a CO_2 machine alone. If no attention is paid to the indicator or recorder, the installation of such apparatus is useless. The records should be carefully watched and studied and adjustments should constantly be made in firing methods until the best percentage of CO_2 is obtained. After the best mark is reached, fluctuation of the CO_2 line below that mark to any great extent should not be allowed.

This chart is based on a flue gas temperature of 600 degrees F., and an outside air temperature of 60 degrees F. Where the flue gas temperature is higher, or the outside air temperature lower, the money loss will be correspondingly increased. On the other hand, with a higher outside air temperature and a lower flue gas temperature, the money loss is proportionatly decreased. Further, in the construction of this chart, it has been assumed that the coal has a calorific value of 14,500 B.t.u. per lb. of combustible.

It may also be interesting to point out that where there is only 3 per cent of CO_2 in the flue gases, 76 per cent of the heat value of the coal passes up the chimney as waste under the conditions outlined above. It is impossible, however, for these gases to contain as low as 2 per cent, because it would require more than the original quantity of heat in the coal to heat the enormous surplus of air to a temperature of 600 degrees F.

A New Pressure Governor for Gas and Liquid Systems.

IN MANY power installations, where air, other gases or liquids must be maintained under pressure, the demand for an automatic method of doing this has arisen.

As a result the General Electric Company has developed a new pressure governor to control standard self-starters for motor operated pumps and compressors. The governor maintains a pressure between predetermined limits on any gas or liquid systems that will not corrode the Bourdon Tube.

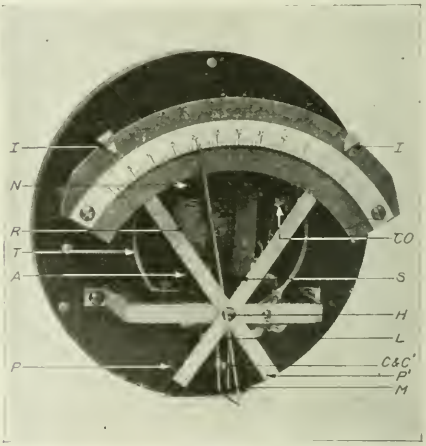
The governor can be used on any standard a.c. or d.c. circuit. It is rated for pressures of 80, 100, 160, 300 or 500 lb. and operates within settings of from 3 to 12 lb. between high and low pressures. Governors for higher pressure are also made.

The governor shown in the accompanying illustration consists of a Bourdon Tube, an indicating needle, a graduated pressure scale, adjustable high and low pressure stops to determine the desired pressure range and a relay which actuates the contacts in the control circuit of the self-starter, all enclosed within a dust proof case, easily opened for inspection.

Action of the governor is dependent on the Bourdon Tube which should be connected to an independent discharge pipe from the pressure tank. The free end of the tube T is mechanically connected to the indicator needle N moving it over the scale as changes of pressure affect the tube.

After the settings for the pressure range have been made, the governor will automatically maintain pressure within those limits. The operation of the pressure governor is as follows:

Assuming that the pressure is at the low value, as indicated by the left-hand indicator I, the contact C on the needle N completes the circuit through the contact C′ on the movable arm M, which at the low pressure points rests against the stop P′. When this contact is



THE INTERNAL MECHANISM FOR A CR 2922 PRESSURE GOVERNOR

made, the circuit is completed through the relay coil R, causing the armature A to close. Attached to this is the contact CO which upon closing, completes the control circuit to the self-starter, causing the motor to start.

The armature is also attached to the spring S which holds the contact C′ firmly against C until contact is broken at P.

As the pressure increases, the needle pointer moves to the right, but its lower part to which the contact C is attached moves to the left, and is followed by the movable arm M. When the high pressure point is reached, the movable arm is prevented from traveling further by stop P and the needle continues its course, breaking the circuit by separating contacts C and C′. The instant the circuit is broken, the relay R is de-energized, its armature falls, releasing the tension of the spring S and because the movable arm M is counterweighted it returns to the stop post P′.

When the pressure is decreased to the minimum value, the contact C again completes the relay coil circuit by engaging contact C′ and the cycle of operation is repeated.

The case is tapped and drilled at the bottom for the pressure pipe and electrical conduit connections.

An Automatic Acid Elevator

AN AUTOMATIC device employing air pressure for blowing acids to higher levels has been developed by the Monarch Manufacturing Works, of Phila., Pa. A patent on the device has been applied for. Fig. 1 is a diagram of the device connected to an acid egg, and Fig. 2 shows the interior construction.

The liquid (acid) flows from low-level tank through the combination check valve and air device into the blow-case. An exhaust check valve EC is placed in the exhaust line, through which air displaced by the in-flowing acid escapes. This exhaust line may be carried back to the filling tank or elsewhere. As the blow-case becomes full of acid, the surging effect created under-

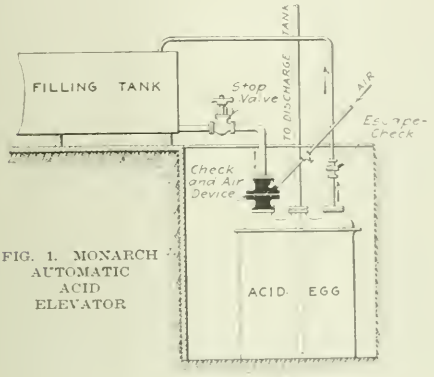


FIG. 1. MONARCH AUTOMATIC ACID ELEVATOR

neath the air valve within the air device proper tends to unseat the air valve (plug), thus allowing compressed air to escape from ports C.A.P. (Fig. 2). This air being under high pressure kicks the air valve up against the under side of the inverted cup-shaped check, carrying both up until the top of the liquid check engages with seat S, thus preventing inflow of liquid or escape of compressed air back to the filling tank. The pressure of the air then acts on top of the liquid within the blow-case, forcing it out the discharge pipe, which as usual, is carried almost to the bottom of the case.

When all the acid has been discharged, there is a sudden rush of air through the discharge pipe, which relieves the pressure within the case, because the area of the air ports C.A.P. is very much smaller than the area of the discharge pipe. The pressure of the air within the blow-case having dropped to practically nothing, allows the air valve and liquid check to fall back into position, the former shutting off the air ports and the latter permitting the re-filling of the blow-case.

The exhaust air check valve EC allows air under low-pressure (exhaust air displaced by the inflowing liquid) to pass, but when the blow-case is filled, a column of liquid rises in the pipe underneath the check EC, and when air pressure is turned on through operation of the automatic air device proper this column of liquid, under pressure, forces the exhaust air check shut, in which position it remains until the blow-case has been emptied and pressure relieved therefrom, as previously explained, when it again opens for escape of displaced air.

By use of this automatic device compressed air is saved to a considerable extent, for the reason that the air is turned off almost instantly the blow-case is emptied, whereas in the hand operated blow-cases, the attendant of course cannot know exactly when the case

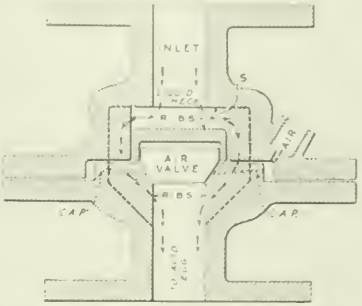

FIG. 2. AUTOMATIC ACID VALVE

is empty, and usually his attention is required by another case or elsewhere, so that it would not be possible for him to turn off the air even though he could know exactly when the case was empty.

New Lamp Screen for Industrial Lighting

A new article for improving industrial lighting has been placed upon the market by the Laco-Philips Co., 131 Hudson St., New York. It is called laco-dalite and consists of a special blue-glass screen that is clamped

FIG. 1. SCREEN AND COVERING FOR INDUSTRIAL LIGHTING

over the bottom of the electric light reflector, thus inclosing the bulb. The light thus filtered through the special blue glass, it is claimed by the manufacturers, is equal to that obtained from the nitrogen lamp. It is white and pure and the equivalent of daylight. The question of proper lighting is important in concentrators, especially for table work at night. Both here and in the draughting room as well as in other places a device of this sort should prove helpful.

Book Reviews

MODERN INORGANIC CHEMISTRY. By *J. W. Mellor*, D. Sc. New edition, crown 8 vo. (13 x 19 cm.), 903 pages, 334 Illustrations. Price $2.50, 7/6. New York and London: Longmans, Green and Co.

The author is well-known for his books on chemical statics and dynamics, and higher mathematics for students of chemistry and physics. In this hand-book for students, and chemists in general, he discusses all the varied phenomena of chemistry, from the simplest to some of the most complex, and after presentation of the facts he draws the evident, or probable, or possible, conclusions as to the theoretical explanation—the *why* and the *wherefore*. Working through this book must be a great exercise in chemical philosophy to the student—a training of his wits, a systematic strengthening of his reasoning powers, an introduction to a higher level of chemical understanding. It cannot but whet the student's appetite for more, and inspire him to higher chemical ambitions. All this can be done by a chemical textbook—when it is written skilfully by a master chemist.

* * *

COAL GAS RESIDUALS. By *Frederick H. Wagner*. 244 pages, illustrated with working diagrams. Price $2.50. New York: McGraw-Hill Book Company, Inc.

In view of the great importance of the by-products of coal to modern industry, especially in its present belligerent phase, it is remarkable that so few books have been written on the subject. One of the few is the volume entitled "Coal Gas Residuals" by Frederick H. Wagner, a second edition of which has recently been issued. This new edition is in many respects a considerable improvement over the first. Information bearing on the uses of the various products in the war has been added that will interest the gas-plant operator who desires a rapid and non-technical summary showing the ultimate useful products derived from the raw materials which he is engaged in producing. The additions include a description of the manufacture of nitric acid from ammonia which has been so important to the German military machine, and a rather hurried resumé of the more important coal tar derivatives and the processes by which they are made. The author has hardly gone far enough in emphasizing the absolute necessity of such products as ammonia, nitric acid, ammonium nitrate, phenol, picric acid, aniline, toluene and trinitrotoluene to a nation at war. In view of the importance that the author attaches to spent oxide as a raw material for sulphuric acid, the chapter on this subject is disappointing because it consists merely in a brief description of the well known processes without even mentioning the peculiar disadvantages of spent oxide and the means that may be employed for overcoming them.

The technical interest and the popular value of the book would be much enhanced if the author had dealt with the important subjects of gas treatment, tar extraction and ammonia recovery from an impartial standpoint instead of being so obviously biased by the theories of the late Dr. Walther Feld. Of many of the Feld ideas, particularly the celebrated series of differential washers so beautifully ideal or ideally beautiful on paper, and so utterly impossible in practice—it may be deeply regretted here in America that they were not at once seized upon and universally adopted *in Germany*, for thereby the downfall of the Kaiser would have been materially accelerated. "As no tar separating plants of the Feld system have as yet been erected in the United States, statements showing results obtained in this branch of by-product recovery will necessarily have to be confined to European practice." The unconsciously pathetic retention of this sentence in the second edition tells its own story. However, frank exploitation does less harm than disguised partiality and Mr. Wagner may be admired for the constancy of his rather lonesome discipleship.

The principal value of the book will be to those who desire a description of the various by-products of coal and the methods and apparatus used in handling them without too many technical details. The descriptions are well written and usually carefully illustrated. The appendix contains a number of tables which the gas engineer and chemist will appreciate, particularly a table of constants for certain gases and vapors. The engineer who desires to obtain a general knowledge of the various systems of ammonia-recovery practiced in Europe will be attracted to the chapter on ammonia, although American practice has contradicted many of the comparative statements given. The Koppers system of benzol recovery and purification is discussed in interesting detail following the outlines of Puening's description.

Personal

At the Annual Meeting of the Chemists Club of New York the following officers were elected to serve for the following year: President, Ellwood Hendrick; vice-president, Charles H. Herty; non-resident vice-president, Charles L. Parsons; secretary, John R. MacPherson Klotz; treasurer, Henry M. Toch; two trustees to serve for three years, Thomas R. Dunning and Kenneth C. McKenzie.

Mr. C. G. Atwater, manager of the agricultural department of the Barrett Co., has taken up active duties with the Ordnance Department as consulting engineer in connection with the government nitrate plant.

Mr. H. Foster Bain has been appointed assistant director of the U. S. Bureau of Mines and is in the office of the bureau at Washington.

Mr. D. J. Coffey, formerly of the Schumacher Mill at Porcupine, has been promoted from mill superintendent to general manager of the Lake Shore properties, situated near Cobalt, Ontario, succeeding John W. Morrison.

Mr. Fred B. Crosby has resigned his position in the power and mining department of the General Electric Co., Schenectady, N. Y., to become electrical engineer of the Morgan Construction Co., Worcester, Mass. Mr. Crosby has specialized in electrical equipment for steel works.

Mr. John M. Eckert, assistant engineer in the gas and oils department of Underwriters' Laboratories, has entered the Ordnance Department, U. S. A., as supervisor of Tests at steel plants in the vicinity of Chicago and also in Ohio, Indiana, Wisconsin and adjoining states. Physical tests, chemical analysis, heat treatment at plants and the instruction of inspectors for this territory will come under Mr. Eckert's direction.

Dr. Rudolph Gahl has resigned from the position of metallurgist, in charge of concentrator, at the Inspiration Consolidated Copper Co., Miami, Arizona, to devote his time to consultation practice. Guy H. Ruggles, formerly mill superintendent for the Humboldt plant of the Consolidated Arizona Smelting plant will succeed Dr. Gahl.

Mr. N. J. Gebert, director of the metallurgical laboratory, Standard Roller Bearing Division of Marlin-Rockwell Corporation, has resigned his position and joined the staff of Mr. Herman A. Holz, New York. Mr. Gebert will be in charge of the metallurgical and magnetic laboratory which Mr. Holz is equipping in the Metropolitan Tower, New York City.

Mr. Justice Grugan has discontinued his mining engineering office at 30 Church Street, to assume the duties of chief engineer for Suffern Company, 135 Broadway, New York.

Mr. E. H. Hamilton, formerly metallurgical manager of the Trail Smelter of the Consolidated Mining and Smelting Company of Canada, has been made smelter superintendent of the Midvale, Utah, plant of the United States Smelting Company to succeed Mr. L. D. Anderson, who was appointed manager of the same plant some time since.

Dr. A. W. Homberger, head of the chemistry department of Wesleyan University, leaves this college after the end of the Spring work and goes to the University of Louisville, Kentucky, to be dean of the chemistry department at that place. Dr. Homberger has been at Wesleyan for seven years.

Mr. ARTHUR HOUGH, consulting chemical and explosives engineer, has joined the staff of the Durion Castings Company in a consulting capacity. Mr. Hough for a number of years past has been engaged in the manufacture of acids and explosives of a general character, and has devoted a great deal of time to the development of products such as trinitro toluol, trinitro benzol, and ethylene glycol for the preparation of dinitro glycol, chlorhydrin for the preparation of mustard gas and monochlor benzol.

Mr. M. T. LOTHROP has been appointed assistant factory manager of the Timken Roller Bearing Company of Canton, Ohio. For the past seven years he has been metallurgist for the company and has also been in charge of the steel and tube departments.

Mr. R. B. MOORE, in charge of the Golden, Colorado, station of the Bureau of Mines, has been visiting Eastern cities in connection with Government business.

Mr. JACQUES S. NEGRU, mining engineer of Denver, Colorado, has enlisted with the Canadian forces and has gone to Winnipeg to be detailed to the Engineers Corps. on Railway work.

Mr. W. C. POTTER, formerly with the A. S. & R. Co., in Mexico, has been appointed head of the Equipment Division of the Signal Corps in charge of production of airplanes and motors for the army.

Mr. J. M. RIORDAN, until recently sales engineer of the Grant Lees Gear Company of Cleveland and formerly representing the Fellows Gear Shaper Company of Springfield, Vermont, in the Central States, is now connected with the sales organization of the Cleveland Milling Machine Company, 18511 Euclid Avenue, Cleveland, Ohio.

Mr. ALBERT TATE SMITH, lately manager of the R. U. V. Company, 50 Broad Street, New York City, has returned to the Permutit Company, with which he was formerly connected, to take the position of assistant manager of sales.

Mr. WILLIAM W. TORRENCE, formerly of the General Electric Company, has been appointed general manager of the Denver Engineering Works Company, succeeding Mr. Lewis Searing, who has resigned.

Mr. H. G. WEIDENTHAL, formerly works manager of the General Steel Company, Milwaukee, Wis., has joined the forces of James H. Herron, Cleveland, Ohio, in the department of steel works design and operation. Mr. Weidenthal will give special attention to electric steel making furnace operation.

Mr. FRED D. WILLIAMS, head of the power specialties department of the H. W. Johns-Manville Co., severed his connection with that company and went to the L. H. Gilmer Co., on April 29, as assistant general manager of the combined properties of that corporation, with headquarters at Tacony, Philadelphia.

Mr. WM. WRAITH, of the International Smelting Co., has been elected president of the Utah Section of the American Institute of Mining Engineers, Walter Fitch of the Chief Consolidated Mining Company vice-president, and F. G. Moses, of the Utah Station of the U. S. Bureau of Mines secretary, at the annual meeting held in Salt Lake City recently.

Current Market Reports

Non-Ferrous Metal Market

Wednesday, May 8.—There is nothing much to report on lead or spelter. The price of tin has advanced.

Copper.—The British government is now making big demands on the producers, who anticipate difficulty in meeting the requirements for copper in May. The copper producers have been in session with the price-fixing committee of the War Industries Board.

Tin.—The London tin market jumped £20 per ton and our market has become unsettled for any business until buyers can see more clearly the reason for this advance. The price in London is £360. Spot tin, Straits tin or Standard tin is not available.

Lead.—The lead position remains quiet and without special feature. The Trust price is 7c. per pound with independents quoting slightly above.

Spelter.—The spelter market continues dull. A little more business is recorded and prices are quoted around 7c. per pound.

Antimony.—A little more business is reported during the past week. The spot market price for antimony regulus is 13c. per pound, with shipments from the Far East quoted at 12½c., duty paid.

Tungsten.—A fair volume of business was done. The prices remain unchanged at $24.00 for high-grade wolframite and $24.50 for high-grade scheelite, although the latter is not so much in demand for immediate delivery as it is for future delivery. In view of the high freight and expense of shipping, the foreign shippers see, if possible, that no material under 60 per cent is shipped to this country.

Manganese.—The Government is contemplating the enactment of regulations whereby a maximum price will be established for domestic manganese ore. Shortage of high-grade ore becomes more and more acute and an increase in schedule price is expected.

Chrome.—Unchanged at $1.50 per unit for 45 per cent grade. Owing to the shipping situation, shipments of foreign chrome ore have virtually ceased. The few thousand tons that happen to be afloat and unsold have fetched as high as $100 per ton. The market for domestic ore is still chaotic, as it has been during the last year.

The Iron and Steel Market

Steel manufacturers have been revising their rolling and shipping schedules to conform to the new requirements of the Washington authorities. The revision, which has been in progress for several weeks, is along two lines: (1) For the diversion of the maximum possible tonnage to government orders, known as classes I and II and representing war material required by the Government and by its allies; (2) A distribution of the remaining steel to the lines of consumption where it will do most good in helping to win the war.

As to the diversion of more steel to direct war orders, an impetus was given to the changes already in progress by the developments at the meeting held in New York, April 26, between J. Leonard Replogle, Director of Steel Supplies under the War Industries Board, and about fifty representative manufacturers. The meeting was held in the office of President Gary of the American Iron and Steel Institute, and the president submitted a pledge, afterwards circulated to all producers, that they should make a maximum effort to furnish all possible steel for the government requirements. The situation was that the War Industries Board had considered the taking over of all steel shipments, and had indeed drawn up an order to that effect, but by reason of the understanding reached at the meeting Mr. Replogle undertook to see that the order was held in abeyance. The War Industries Board does not desire to take over the distribution of the so-called "commercial" steel unless such action proves necessary, and much prefers that the steel producers make the distribution of steel themselves. In this distribution it will furnish all the aid and advice possible. The board has already made known that among the commercial uses, coming after direct government orders, the highest classifications should be steel for the development of oil production and the transport of oil, and steel required in agricultural pursuits. This decision helps the steel trade considerably but makes only a beginning in the allotment to the number of gradations from

the most essential to the least essential lines of steel consumption. Of sacrifices for the war there is no end, and one sacrifice is that of diction, since in normal times the word "essential" is hardly used in the comparative degree.

War Steel Requirements

The shipbuilding operation calls for much more steel than was estimated by producers, even quite recently. In the first place, vessel completions have been steadily increasing, being in the first fortnight of May at the rate of more than 4,000,000 tons deadweight per annum, representing at least 2,000,000 gross tons of steel. In the second place, vessel launchings are at a greater rate than vessel completions. In the third place, keels laid are at a greater rate than launchings, as they represent prospective completions of several months hence. Finally, it is desired to accumulate fabricated parts at shipyards and steel for fabricating at the various fabricating plants, both for the purpose of facilitating the current work and for the purpose of accumulating a reserve against contingencies, including the possibility of traffic difficulties next winter.

Shell steel requirements have been increasing rapidly, as forging capacity has been increased. The forging capacity has been quite below the capacity of the shell making factories, but the shortage has now been eliminated entirely, except as to shells 6-inch and larger, and that situation is expected shortly to be righted.

Structural requirements have been increasing, and there is even a statement that the government requirements in fitted structural work exceed by 20 per cent the average amount of fabricating work done in the past three years, for commercial purposes.

Orders for approximately 100,000 freight cars have been placed, involving more than 1,000,000 gross tons of steel, including plates, shapes, bars, wheels, etc. The cars are to be built according to the original plans, involving substantially the usual employment of steel, except that the inside roof is used on box cars, involving about 400 pounds per car of galvanized sheets, instead of the more modern all-steel construction involving more than double as much. The War Industries Board requires, however, that the Railroad Administration accept Bessemer steel in plates, etc., when it is more convenient for the mills to furnish Bessemer than open-hearth.

Bessemer steel is also to be used for rails, in all probability. Reports from Washington relating to prospective "orders" for Bessemer rails are somewhat misleading. The railroads have a large tonnage of rails now on order at the mills. There will be only very limited tonnages ordered afresh, but it will probably be required that on many of the orders on books, originally entered for open-hearth steel, Bessemer will be required instead. On account of the two $5 a ton advances that occurred in 1916, and the long delays in filling old orders, the orders now on books are for Bessemer rails at $28, $33 and $38 and for open-hearth rails at $30, $35 and $40.

Commercial Market Remains

Reports that there is no commercial market for steel are an exaggeration, for effect. The large mills as a rule are adhering to former practice and as shipments are made to regular commercial customers they enter additional tonnages for them, but with absolutely no promise, or even intimation, as to the probable time of delivery. Shipments on old orders are to be made, as already indicated, in accordance with the availability of steel, after direct government orders are taken care of, in accordance with the degree of importance of the item of steel consumption involved.

There is, of course, a great deal of steel left while mills are taking care of government orders to the fullest extent possible. Such remaining steel falls into four classes: (1) Rejected ingots under government specifications; (2) crops required to be taken under government specifications; (3) Bessemer steel left after the relatively small proportion is furnished that is acceptable under government orders, and after the requirements of the tin plate trade are met; (4) steel at mills whose finishing capacity is limited, in the forms in which the government can use steel. Thus, as to the last item, there are mills equipped to roll little but merchant bars, the government requirements in that line being very much less than in plates, for example. There has been talk of attempting to divert ingots or billets from such mills to mills equipped with excess rolling capacity in government forms, but the proposition faces great difficulties.

As to the applicability of bessemer steel uses for which open-hearth has in recent years been given preference, the whims of consumers long recognized by steel makers are being given no attention. Of particular interest is the "sanitary" can, the can which does without solder by employing a tight seam. Since the development of the sanitary can and until quite recently open-hearth steel was regarded as absolutely essential, but practically all sanitary cans are now made of bessemer steel. The tin plate maker has to give the black plate special treatment in annealing. This involves an extra expense but it can readily be done.

Production

Production of pig iron and steel has been steadily increasing, although rather slowly. Blast furnace capacity is estimated conservatively at 43,000,000 tons a year, taking the actual production in 1916 plus a safe allowance for new furnaces completed. Steel ingot capacity is 47,000,000 tons at a conservative estimate. Thus far in May pig iron production has been at 90 per cent of capacity at least, but ingot production has hardly been at as much as 90 per cent of capacity. Whatever might be the experience in normal times, it is quite improbable that 100 per cent operation of the blast furnaces would permit 100 per cent operation of the steel capacity, because there is not sufficient scrap.

Chemical Market

Coal Tar Products: The demand for crudes has not undergone a great deal of change during the interval and continues quiet, with prices easier. The intermediates however are in better demand and prices for the most part are unchanged, with a tendency upward rather than otherwise.

Benzol: Large surplus offerings continue to back up on the market. Consumers are not buying heavily and prices registered further declines.

Phenol: Offers are more liberal, but the demand is light and prices are easier.

Toluol: Producers of the dye intermediates are receiving more liberal releases from the government, but other producers of intermediates are not receiving any. There continues to be small outside offerings at high prices.

Naphthalene: Quiet continues to prevail in this situation. Offers are more liberal, with the demand only routine.

Benzoate of Soda: There appears to be larger quantities of this material on the market than heretofore and prices are easing off as a result.

Dimethylaniline: Only a few producers are offering and prices are holding firm, with an active demand.

Diethylaniline: The production is confined to a few quarters and is not heavy; prices are inclined higher.

Paranitraniline: Only a few producers are offering; prices are higher, with an active demand.

Aniline Oil: Inquiries are numerous with prices unchanged.

Beta Naphthol: The technical grade is quite active, but the sublimed is quiet, with prices unchanged.

Alpha Naphthylamine: More of this material has been moving of late than formerly. Prices are practically unchanged, but the spot supply is lower.

Metatolumylenediamine: Recent releases of toluol have assisted toward increasing the production; the demand is active but not heavy.

Para Amido Phenol: Competing factors keep prices low and the production ample.

Phthalic Anhydride: This item is also lower in price due to the competition prevailing.

HEAVY CHEMICALS: Business in products under this classification has been comparatively slow and unimportant during the past two weeks and the tendency in values has been to lower levels. Trading has mostly been in small lots and consumers apparently will not cover far forward needs at present trading levels. In a few of the products there have been pronounced flurries, due in some instances to speculation and in other directions to sudden demands from consuming trades.

Caustic Soda: A marked decline has occurred in this product since our last report and there has been very little important buying for the account of consumers. Prices have dropped from the level of 5c. store New York down to 4.35, at which offers are noted at the moment of writing. Philadelphia has sold material as low as 4.25. For forward positions producers have also come down in their views and there are now offers noted for contracts over the balance of the year at 4.75 works after the price of 5c. works prevailed for a long time. For 1919 business 3¼c. works basis 60% is quoted but no business is noted.

Soda Ash: This market has also been subject to a sharp decline in values, and at the moment of writing bags are available from New York store at 2.15—the lowest price that has prevailed for a lengthy period. Barrels are held at 2.60 to 2.70 and are somewhat firmer than bags, although there is no special movement noted.

Acetic Acid: This market has been one of the features of the situation the past two weeks. The 28% material has sold as high as 16c. barrels inclusive and the 56% material has sold at the unusually high price of 27¾c. barrels extra. This is probably the highest price on record. The principal accomplishment in the product at the moment is the locating of the supplies. Once stocks are located it is merely a matter of a few moments before the product is sold.

Sulphuric Acid: The market has been easier of late and sixty-six degree brimstone acid has been available as low as $33.00 per ton in sellers tanks works. The producers generally ask $35.00 sellers tanks works for the ordinary run of business. Very few offers of sixty degree material are noted, for as a rule the buyer prefers sixty-six degree material when same is available at a favorable figure. Ninety-seven per cent plus acid has on the other hand been very scarce and offers have been few and far between.

Oleum: The situation has improved the past few days and offers have been somewhat restricted. However it is still possible to do $65 drums extra but returnable for ordinary business. For tanks cars possibly $60.00 is workable. Some business in 60% oleum has been done at $225.00 per ton but the production has now been sold for the entire year and no further offers are noted.

Yellow Prussiate of Soda: The consuming demand has been so urgent that prices have been forced up to 50c., although transactions were noted at 37c. only a week or so ago. The production is confined to a few firms and is apparently not sufficiently large to take care of the consuming demand.

Yellow Prussiate of Potash: In common with most potash products the product is easier and there were offers during the past few days at $1.15 without attracting buyers. This is for American material. Japanese material is generally available at a somewhat lower figure.

Cyanide of Soda: The ordinary seller asks 40c. and upward but from second hands it is possible to do 38c. and on large business even this figure is shaded.

Copper Sulphate: Producers are not inclined to meet second-hand prices, but there is no denying the fact that these quotations are rather well establishing the market. Standard brands are available as low as 8¾c., although makers are quoting 9c. and even 9¼c.

Bichromate of Soda: The market has been such that it has been impossible to fathom it. Business has passed from 21c. up to 25c., and at the moment of writing 23½c. and 24c. is quoted. A few casks offered here and there are 23½c. and then a car is picked up at 24c. No one seems to understand just what is going on and who is doing it, but the product is subject to more fluctuation than any other chemical in this classification.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, MAY 8, 1918

Acetic anhydride	lb.	1 50 —	1 60
Acetone, drums	lb	Nominal

Pyrites' domestic	unit	.28	—	.30

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

The ALLEN MANUFACTURING COMPANY, Quakertown, N. J. Capital, $10,000. To engage in the manufacture of chemicals and allied products. Incorporators: Harry W. Hayer, Walter A. Allen, Harry M. Oakes and George E. Rose, Quakertown.

The AMERICAN INGRAFT COMPANY, INC., New York. Capital, $25,000. To manufacture chemicals, etc. Morris Yedlin, Brooklyn, is the principal incorporator.

The BROWN CHEMICAL COMPANY, Maplewood, N. J. Capital, $500,000. To manufacture chemicals and allied specialties. Incorporators: Oscar G. Brown, F. M. Brown, Maplewood, and Arthur C. Hamilton, West Orange.

The CAPSTAN GLASS COMPANY, Philadelphia, Pa. Capital, $300,000. To engage in the manufacture of glass and glassware. Incorporators: H. A. Stein, Sharon Hill, Pa.; J. V. Pimm and S. C. Seymour, Camden, N. J.

The CHRISMAN PARAFFINE PAINT WORKS, INC., Eldrad, Pa. Capital, $20,000. To manufacture paints, varnishes, &c. Incorporators: Benjamin G. McFall, Bruce H. Clark and Frank F. Mack, Eldrad, Pa.

KELLY BROTHERS MANUFACTURING COMPANY, Belington, W. Va. Capital, $50,000. To operate a local foundry. Incorporators: J. F., M. J. and J. P. Kelly, Elkins; J. A. and H. V. Viquesney, Belington.

The KNICKERBOCKER DYESTUFF COMPAY, New York. Capital, $10,000. To engage in the manufacture of dyestuffs, etc. Incorporators: M. Mackenzie, A. H. Gleason and J. J. Hayden, 258 Broadway.

The MANCHESTER SUGAR COMPANY, Boston, Mass. Capital, $50,000. To manufacture sugar. Incorporators: Benjamin P. Levy, N. Harrison and I. Gordon, Boston.

The MALMEE IRON & STEEL COMPANY, Toledo, O. Capital, $50,000. To engage in the manufacture of iron and steel products. George W. Ritter is the principal incorporator.

The METRO COLOR & CHEMICAL WORKS, Brooklyn, N. Y. Capital, $75,000. To operate a plant for the manufacture of chemicals, dyestuffs, etc. Incorporators: A. Petersen, M. Goldhammer and R. Jensen, 760 St. Ann's Avenue.

The MIDDLESEX RENDERING COMPANY, Middletown, Conn. Capital, $25,000. To operate a local rendering plant. Incorporators: Berkley C. Stone, Frank H. Frissell and Dennis J. O'Brien, Middletown.

The NEW ERA ORE REDUCTION COMPANY, Philadelphia, Pa. Capital, $2,500,000. To engage in the development of mining properties and the reduction of ore. Incorporators: Wray C. Arnold, Harold C. Lansinger and M. Elliott, Philadelphia.

The O'BRIEN SYNTHETIC DYE COMPANY, South Bend, Ind. Capital, $50,000. To manufacture chemicals, dyestuffs, etc. Incorporators: Jerome J. Crowley, George L. O'Brien, Will G. Crabill, S. J. Crumpacker and Ray Heylman, South Bend.

The POUGHKEEPSIE PAINT COMPANY, Poughkeepsie, N. Y. Capital, $10,000. To manufacture paints, varnishes, etc. Incorporators: H. Lloyd, Jr., C. and H. Sague, Poughkeepsie.

The PROSPECT PAINT COMPANY, Bronx, N. Y. Nominal capital, $5,000. To operate a plant for the production of paints. Incorporators: F. Eisen, S. Roth and S. Hauptman, 1066 Prospect Avenue.

The PYODINE CHEMICAL COMPANY, Los Angeles, Cal. Capital, $25,000. To engage in the manufacture of chemicals, etc. Incorporators: Dr. David Osterhold, E. Osterhold and Fred E. Osterhold, 1141 North Coronado Street.

The PYROPHORIC METALS COMPANY, Newark, N. J. Capital, $100,000. To deal in metals and alloys. Incorporators: George W. Cunningham, Paterson; William E. Bloomfield, and William Bonnamy, Passaic, N. J.

The SEMINOLE PHOSPHATE MINING COMPANY, Croom, Fla. Capital, $20,000. To mine for phosphate. Incorporators: W. F. Walker, E. N. Morrow, Croom, and A. I. Pelway, Eastman, Ga.

The VELORA COMPANY, New York. Capital, $250,000. To engage in the manufacture of chemicals, etc. Incorporators: E. S. M. Selig, A. B. Crawford and F. Aranow, 27 Cedar Street.

S. WALTER, INC., Philadelphia, Pa. Capital, $75,000. To engage in the manufacture of paper and paper products. Harry Lefkowith is the principal incorporator.

The WATERVILLE FOUNDRY & MANUFACTURING COMPANY, Waterville, N. Y. Capital, $25,000. To operate a foundry for the manufacture of castings and machinery. Incorporators: William G. McLean, Charles W. McLean, Waterville, and George I. Hovey, Deansboro.

The WEST VIRGINIA LEAD & ZINC COMPANY, Parkersburg, W. Va. Capital, $300,000. To engage in the development of lead and zinc properties in the Miami district, Okla. Incorporators: Charles Heinselman, A. D. Sees, A. A. Haught and H. B. Reid.

The WILMINGTON PAINT & GLASS COMPANY, Wilmington, Del. Capital, $50,000. To operate a plant for the manufacture of paints, glass, etc. Incorporators: Harry B. Patten, William F. Johnson and John L. Byrne, Wilmington.

Constructions and Operation

Connecticut

HARTFORD.—U. S. Ordnance Corps, Washington, D. C., will build a plant here and install machinery for producing toluol from gas. Hartford City Gas Co., 565 Main St., will produce about 50,000 gal.

NEW BRITAIN.—The New Britain Machine Co., Chestnut St., has purchased a site of land on South St. on which they plan to construct a 100 x 310 ft factory to cost approximately $125,000.

Georgia

MACON.—The Macon Gas Co. will build a $40,000 addition to its plant, increasing the monthly capacity to 36,000,000 cu. ft gas for lighting and heating.

Illinois

CHICAGO.—Bauer & Black, 25th St and Dearborn Ave., manufacturer of druggist specialties, will build a 7-story, 75 x 108 reinforced concrete addition to factory. Hobart & Roche, 1101 Monroe Bldg., architects.

CHICAGO.—Harrington & King Co., 614 North Union Ave., manufacturer of perforated sheet metal, will build a 1-story 126 x 372 ft mill construction factory at Campbell and Taylor Sts. George C. Nimmons & Co., 2005 Peoples Gas Building, engineer.

Kentucky

NEW ALBANY.—The United Chemical Co., 111 West Washington St., Chicago, Ill., has acquired a tract of land in New Albany comprising about 55 acres on which they plan to construct a large plant for the manufacture of chemicals.

Maine

BIDDEFORD.—The Saco-Lowell Shops, Biddeford, has awarded the contract for the construction of a 1-story, 56 x 92 x 107 ft. brick and steel factory addition to the Flint Building & Construction Co., 146 Main St., Palmer, Mass.

Maryland

BALTIMORE.—The Bartlett Hayward Co., Scott and McHenry Sts., has awarded the contract for the construction of a 1-story, 50 x 75 ft. assembly shop to the Bruce Foundry Bldg., Baltimore, at a cost $55,000.

CLEVELAND.—The Kelly-Springfield Tire Co., Cook St., Akron, Ohio, will build a new plant here to cost approximately $1,000,000.

Massachusetts

HOLYOKE.—The Worthington Pump & Machinery Corporation, Beane Works, Appleton St., is planning to build a 150 x 200 ft. machine and erecting shop, and a 50 x 300 ft. foundry, brick and steel frame. Estimated cost, $225,000. Lyman R. Howes, c/o Beane Works, is engineer.

SOMERVILLE.—The Vacuum Co., 105 Mystic Ave., has awarded the contract for the construction of a 2-story, 60 x 198 ft. timber fumigating plant on concrete pile foundation, to Barney Ahlers Corporation, 110 West 40th St., New York City. Estimated cost, $15,000.

Michigan

DETROIT.—The Packard Motor Car Co., East Grand Boulevard, will build an addition to its factory on Mt. Elliott Ave., to cost $15,000.

Minnesota

MINNEAPOLIS.—Goldberg Bros., 922 Washington Ave., will build a 1-story, 13 x 40 x 80 ft., brick brass foundry by day labor. Estimated cost, $4,500.

New Jersey

KEARNY.—(Arlington P. O.)—Swift & Co., Union Stock Yards, Chicago, Ill., will build a 5 story, reinforced concrete rendering plant on the Kearny Meadows to have a capacity of approximately 3,000,000 pounds of raw product. The company plans to complete the plant in three months and it will probably be the largest works of its kind in the east.

BLOOMFIELD.—The General Electric Co., Sprague Works, has awarded the contract for the construction of a 1-story, 100 x 160 ft., reinforced concrete steel and brick factory, to Austin Co., 16112 Euclid Avenue, Cleveland, Ohio. Estimated cost, $35,000

HASKELL.—The E. I. duPont de Nemours Co., Wilmington, Del., is building a 1-story, 20 x 40 ft. addition to its plant here. James Lynah is superintendent.

NEWARK.—The Rutterworth Judson Corporation, Avenue R, manufacturer of chemicals, has had plans prepared for the construction of a 1 story, brick and steel absorption tower at its plant here. Estimated cost $30,000.

New York

BROOKLYN.—The Long Island Soap Co., Bridgewater St. and Meeker Ave., has awarded the contract for the construction of a 3 story, reinforced-concrete factory, to the Gabler Construction Co., 402 Hudson St., New York. Estimated cost, $38,000

NEW YORK.—The American Balso Corporation, manufacturer of chemicals, 20 East 42nd St., has awarded the contract for the construction of a 1 story, 138 x 185 ft., concrete, brick and steel factory to be built at the foot of 153rd St. and Harlem River to C. G. Flygar, 405 Lexington Ave., New York. Estimated cost, $70,000.

NEW YORK.—The Vulcan Proofing Co., 583 Dean St., Brooklyn, has awarded the contract for the construction of a 2 story 120 x 208 ft. concrete factory on 57th St., west of 1st Ave., to Turner Construction Co., 244 Madison Ave., New York. Estimated cost, $200,000.

TUCKAHOE.—The Hodgeman Rubber Co. has awarded the contract for the construction of a 1 story 60 x 160 ft. concrete, brick and steel factory to cost $20,000 to Austin Co., 16112 Euclid Ave., Cleveland, Ohio.

WATERTOWN.—Fire May 4 destroyed the machine mill at the plant of the International Paper Co., on Sewalls Island with a loss of approximately $150,000. The company plans to rebuild same.

North Dakota

GRAND FORKS.—The University of [illegible] has awarded the contract for the construction of a 3 story chemistry building to the Dakota Construction Co., Grand Forks, Minnesota. Mine [illegible]

Ohio

AKRON.—The Goodyear Tire & Rubber Co., Main St., has awarded the contract for the construction of a 1 story

170 x 460 ft., steel, brick and concrete balloon factory, to the Hankin-Conkey Construction Co., 321 Cuyahoga Building, Cleveland. Estimated cost, $450,000.

AKRON—The Phoenix Rubber Co., Wrigley Ave. has awarded the contract for the construction of a 1 story, 50 x 100 ft., and a 1 story, 30 x 30 ft., brick and steel frame factory, to Clemmer & Johnson Co., High and Church Sts., Akron, to cost, $8000.

CINCINNATI—The Cincinnati Ball Crank Co. plans to build a brick machine shop as an addition to its factory at 3167 Densey Ave., Oakley. Estimated cost, $35,-000.

CINCINNATI—The contract has been awarded to the Fisher-DeVore Electric Co. for the construction of a 6 story, reinforced concrete plant for the Lullaw-Dunn-Gordon Co., machine tool manufacturers. Estimated cost $90,000.

CINCINNATI—The Peerless Foundry Co., 11th and High Sts., Hamilton, will build a 120 x 200 ft. grey iron foundry, fireproof construction.

CINCINNATI—The United States Electric Tool Co. plans to build a 2 story, brick manufacturing building at 2488 West 6th St. Estimated cost, $15,000.

CLEVELAND—The Aluminum Rolling Mills Co., Ivanhoe Rd., will build a 1 story 81 x 399 ft., concrete, brick, and steel aluminum rolling mill. Estimated cost, $100,000.

CLEVELAND—The Globe Machine & Stamping Co., 1250 West 76th St., has awarded the contract for the construction of a 4 story, 100 x 150 ft., steel and brick metal factory, to Craig Curtis Co., 1031 Guardian Bldg., Cleveland. Estimated cost $125,000.

CLEVELAND—The Hoffman Bronze Co. Addison Rd., has awarded the contract for the construction of a 1 story, 50 x 101 ft., brick bronze foundry, to A. H. Howard, 1528 Larchmont Ave., Cleveland. Estimated cost, $10,000.

CLEVELAND—The Masek Glue Co., 908 Denison Ave., has awarded the contract for the construction of a 1 story, 30 x 60 ft., brick and steel glue factory, also a 2 story, 20 x 88 ft., reinforced concrete, brick and steel reduction plant, to the Masters & Mullen Construction Co., Electric Building, Cleveland. Estimated cost, $40,000.

CLEVELAND—The Parrish-Bingham Co., 10600 Madison Ave., has awarded the contract for the construction of a 1 story, 120 x 144 ft. building for hardening and picking steel, to W. I. Thompson & Son Co. Estimated cost, $30,000.

CLEVELAND—The Standard Foundry and Manufacturing Co., 2717 East 75th St., has awarded the contract for the construction of a 1 story 35 x 100 ft., brick and steel factory, to D. Lindhorst Construction Co., 807 American Trust Building, Cleveland. Estimated cost $5,000.

DAYTON—The Machines Co., Essex Ave., will build a 3 story, 70 x 150 ft., reinforced concrete and brick factory for the manufacture of optical instruments. Estimated cost, $75,000.

DAYTON—The Ohmer Fare Register Co., Bolander Ave., has awarded the contract for the construction of a 1 story 90 x 300 ft., reinforced concrete, steel, and brick factory to cost $50,000, to Blanchard Contracting Co., 601 Reibold Building, Dayton.

Pennsylvania

CHESTER—John A. Worrell, 905 West 8th St., will construct a 1 story brass foundry at 8th and Springwell Sts.

PHILADELPHIA—The American Manganese Bronze Co., Rhawn and Hegerman Sts., has had plans prepared for the construction of an addition to its foundry in Holmesburg.

PHILADELPHIA—The Fairmount Foundry Co., Mascher and Duncannon Sts., will construct a 1 story, 22 x 100 ft., addition to its foundry.

PHILADELPHIA—John T. Lewis & Sons Co., Lafayette Building, has awarded the contract for the construction of a 1 story, 108 x 180 ft., brick and steel building, at Aramingo and Huntingdon Aves., to the Turner Concrete Steel Co., 1713 Sansom St., Philadelphia. Estimated cost, $10,000.

PHILADELPHIA—Wm. Sellers & Co., 16th and Hamilton Sts., will build a 5 story, 27 x 50 ft., brick, concrete, and steel addition to its plant to be used as an injector shop, to cost $15,000.

PHILADELPHIA—C. F. Simmons Sons, Belgrade and Tioga Sts., has awarded the contract for the construction of a 1 story 35 x 100 ft., brick factory addition for the manufacture of fertilizers and oils, to Harry Gill, Jr., 2515 Germantown Ave. Estimated cost $7000.

PITTSBURGH—The E. R. Moore Co., Union Bank Building, has awarded the contract for the construction of a 1 story, 65 x 200 and 60 x 160 ft., reinforced concrete, brick and steel factory building, to Austin Co., 16112 Euclid Ave., Cleveland, Ohio. Estimated cost $45,000.

Rhode Island

PAWTUCKET—The Narragansett Machine Co., Vale St., has awarded the contract for the construction of a 2 story 60 x 130 and 50 x 86 ft. reinforced concrete, brick and steel manufacturing building, to W. H. Hamlyn & Son., 35 Greenwich St., Providence. Estimated cost, $50,000.

Tennessee

CHATTANOOGA—(Alton Park)—The F. J. Lewis Manufacturing Co., 2513 South Robey St., Chicago, Ill., manufacturer of roofing, etc., has purchased a site at Alton Park on which they plan to construct a branch factory.

Virginia

PULASKI—The Pulaski Foundry & Manufacturing Co. plans to build an addition to its foundry here which will double the present capacity.

Wisconsin

CUDAHY—The Great Lakes Rubber Co., Milwaukee, recently incorporated, plans to construct a factory here for the production of molded and mechanical rubber goods. First unit of plant will provide for 40,-000 sq. ft. space. Donald C. Barbee, 140 Reed St., Milwaukee, is interested.

MILWAUKEE—The Federal Malleable Co., 299-323 Sixty Fourth Ave., plans to build an addition to its foundry at West Allis.

WATERTOWN—The Monarch Tractor Co., Watertown, has awarded the contract for the construction of a 140 x 160 ft., brick and steel machine shop and assembly unit, to the Austin Co., 16112 Euclid Ave., Cleveland, Ohio.

New Publications

THE COLLAPSE OF SHORT THIN TUBES. By Prof. A. P. Carman of the University of Illinois. Bulletin 99 of the Engineering Experiment Station, Urbana, Ill.

THE REPUBLIC OF BOLIVIA. Official Information and Statistics, Summarized by Señor Julio Zamora, Minister of Foreign Relations, Woolworth Bldg., New York.

EMERGENCY TRAINING IN SHIPBUILDING. Description of Evening and Part-Time Classes for Shipyard Workers. Bulletin No. 3 of Federal Board for Vocational Education, Washington.

MECHANICAL AND TECHNICAL TRAINING FOR CONSCRIPTED MEN. (Air Division U. S. Signal Corps). Bulletin No. 4, Federal Board for Vocational Education, Washington.

MINERAL INDUSTRIES OF THE UNITED STATES. The following publications have been issued by the Smithsonian Institute, Washington. Bulletin 102, Parts 1, 2 and 3: Coal Products. By Chester G. Gilbert; Fertilizer. By Joseph E. Pogue; Sulphur. By Joseph E. Pogue.

NEW BUREAU OF MINES PUBLICATIONS: The Mining Industry in Alaska. By S. S. Smith. Bulletin 153.

NEW BUREAU OF STANDARDS PUBLICATIONS: Combined Table of Sizes in the Principal Wire Gages. Circular 67. Gas Interferometer Calibration. By J. D. Edwards. Scientific Paper No. 316; Latent Heat of Vaporization of Ammonia. By Nathan S. Osborne and M. S. Van Dusen. Scientific Paper No. 315; Latent Heat of Pressure Variation of Liquid Ammonia. By Nathan S. Osborne and M. S. Van Dusen. Scientific Paper No. 314; Specific Heat of Liquid Ammonia. By Nathan S. Osborne and M. S. Van Dusen. No 95, Durability of Cement Drain-tile and Concrete in Alkali Soils. By R. J. Wig, G. M. Williams, A. N. Finn, S. H. McGrory, E. C. Bebb, and L. R. Ferguson. No 310, Some Electrical Properties of Silver Sulphite, by George W. Vinal.

BULLETIN NO. 16, MINERAL SPRINGS OF CANADA (in two parts). Part 1. The Radioactivity of some Canadian Mineral Springs. By John Satterly and R. T. Elworthy. Issued by the Canadian Department of Mines, Ottawa, Can.

Manufacturers' Catalogs

DRIVER-HARRIS COMPANY, Harrison, N. J., have recently issued a bulletin on the subject of pure sheet nickel. Another bulletin on "Nichrome" wire mesh containers for heat treating and acid cleaning is in the course of preparation.

THE BAILEY METER COMPANY, 141 Milk St., Boston, Mass., has issued Bulletin No. 41 entitled "How to Save Coal."

THE JEFFREY MANUFACTURING CO., Columbus, Ohio, has issued Catalog 231, describing Jeffrey storage battery locomotives for industrial plants.

THE LINK-BELT CO., Chicago, Ill., has issued Book No. 358 describing Link-Belt roller chain.

THE MERCHANTS NATIONAL BANK, 28 State St., Boston, Mass., has issued through its Textile Dept. a booklet on the Motor Truck Problem in the textile and allied industries.

THE WHEELER CONDENSER & ENGINEERING CO., Carteret, N. J., has issued a handbook of steam tables especially for condenser work.

THE MAGNESIA ASSOCIATION OF AMERICA, 702 Bulletin Bldg., Phila. Pa., has issued the first Anniversary Portfolio of the Magnesia Association, under the general title "Let 85% Magnesia Defend Your Steam." The book is a large assemblage of all the educational publicity regarding this insulation which has been appearing during 1917.

LUDLUM ELECTRIC FURNACE CORPORATION, Woolworth Bldg., New York, has published a catalog of its furnace for making cast steel, cast iron, low-phosphorus pig iron and washed metal from low-grade iron and steel scrap. Four points of excellence in design and operation are discussed. The furnace is made in 5, 10 and 15-ton sizes.

HUNGERFORD & TERRY, INC., Philadelphia, have issued a new catalog on water filters for industrial purposes, describing pressure and gravity filters and water softeners.

Americanism

IF WE do not beat the Germans they will beat us. If the war should end in a draw it is also likely to involve a German victory of the most sinister kind, and for this reason: Unless they become ashamed of themselves in the light of defeat—which seems their only possible source of illumination—Germans who acknowledge the Imperial Government as it is constituted will continue in their abject obedience to any representative of Imperial Authority. They will proceed to lie and practise deceit and offer bribes and foment discord and do any dirty trick they are told to do. Any precious Regierungsassessor or Rat (which is a much-wished-for and instructive title), represents the All-Highest, and it is the interpretation of the wishes of the All-Highest through these media which is the unwritten German law that knows neither ethics nor honor.

Let us hope, however, that in time the German army and navy will be sufficiently shot up to see that it does not pay to rob and steal, and torture prisoners and commit atrocities to show their barbarous prowess, and that finally they may be driven home to worry out their salvation around their own hearthstones. Even then we shall have a stupendous task before us. How long it will be before these acknowledged world-butchers will be allowed to sit at table in conference or stand on the same footing with self-respecting men, whether white or yellow, rests in the hidden lap of the future. To meet them as equals in their present temper, also means defeat. We have gone to war because the Germans were not good enough, and we mean good in the old-fashioned sense of living in sympathy, and taking responsibility for all men of good-will. We have learned already that it will not do to take German ways for our example any more, although we acknowledge the German people to be brave and loyal and competent and efficient. The point is that ethically they have become blind.

Somehow, in the new order of things, we must be strong in many places where we have been weak, if we would avoid the pariah fate of the Germans. New conventions of righteousness must be established. They must become part of the folkways, or attitudes of mind that we expect of everybody. We have dwelt in somewhat of a fool's paradise, leaving admonition to the clergy and rules of conduct to the legislators. But the clergyman has had his own establishment to advance, and his emphasis upon unimportant delinquencies in the interest of his organization has cost him his post of ethical arbiter. The legislator records public opinion in the laws which he helps to enact; he rarely makes public opinion. Moreover, writing ambitions upon the statute books, as we often do, is far from fruitful in good results.

We repeat, there must be new conventions of righteousness established if we are to go forward as a nation on the one hand and avoid the depravity of the Germans on the other. These new conventions will have to do rather with things to be accomplished than with things forbidden. We have seen some very mean and pernicious exploitations of labor in this country and the trouble isn't cured when the evil practices are made illegal. The employment of labor carries with it grave responsibilities; responsibilities that go far beyond the mere purchase of work. And one of the first of these is to see to it that good men and women who do not know the national language and customs shall have a chance to learn them and to become American citizens.

One of the most illuminating men we ever met started in this country as a Neapolitan laborer, in a gang, under a padrone. He could neither read nor write Italian and he knew no other speech. An explosion of dynamite killed a number of his fellows and he was picked up for dead with the upper part of his face, including his eyes, blown clean away. A spark of life was left in him, so he was taken to the hospital where he became interesting for the sole reason that he did not die. When he recovered he was by good fortune sent to that best of the institutions for the blind at Overbrook, Pennsylvania, where he learned first to read and write his own language. Then he mastered English, then French and Spanish and German and then, out of sport and to help him in his work, he took up Russian and a number of other Slavic languages. He now wanders about by himself in New Jersey and Pennsylvania, looking up neglected blind persons and sees to it that they are taught to read Braille, to write on a typewriter, and that they learn trades. Free and with all his faculties, he would have remained a Guinea, worth so much a day and no more, housed in a shack and with no outlook upon life.

Such qualities of exalted citizenship are here and they are available; available, we might almost say, on every hand. If they are turned into destructive channels there is usually a reason why. The incidence of blame is in neglect, and we are learning where to look for it. The time has already arrived when employers must pay something more than wages to their men with hands. The laws generally make it unprofitable to avoid the assurance of physical safety, but that is not all. These men and women must have the chance to become good Americans, they must have decent housing conditions, their children must have good schooling and the opportunity to grow up without corrupting influences.

We know an old gentleman who employs about a thousand men and women. It is surprising to note, in talking with them at hap-hazard, the breadth of mind, the sanity of view and the general indications of culture among them. These qualities seem to increase according to their periods of employment in his establishment. He doesn't preach or lecture or make any fuss over them. He doesn't put on airs or patronize them. But he puts into his daily task the kind of headwork and heart-work that American employers must learn to exercise lest they fail in greater measure than bankruptcy itself; lest they fail in the ideals for which our boys are giving their lives.

The Present Situation in Oil Shale

SOMETHING verging on an old-fashioned "boom" is taking place in oil shales, if the word of the promoter is accepted without discount. Up and down the busiest streets of more than one Western city may be seen show windows containing a mercury retort heated by a plumber's torch, a condenser and one or two Wolff bottles, with which apparatus "liquid gold" or "pure oil" is extracted from a heap of dirt tastefully arranged alongside. Posters remind the observer that three cents invested in Bell Telephone netted three dollars (or thirty dollars—depending upon the fancy of the sign artist) while the furnishing of the office itself consists principally of a desk inhabited by a more oily and efficient gold-extractor in human guise.

The activity of many of these paper companies is no doubt made possible by the lack of "blue-sky" laws, and inspired by the recent report of D. E. Winchester of the U. S. G. S. estimating the amount of material recoverable from the shales in Colorado alone to be of the order of twenty billion barrels of crude oil, two billion barrels of gasoline, and three hundred million tons of ammonium sulphate. Assuming at least an equal amount locked up in the same but less well examined formation in Utah and Wyoming, it appears that here is a reserve of oil products with many times the total holdings of our combined oil fields.

It will probably be found that there will be little profit in mining and distilling shale to sell to outside refining companies. As in other industries, the refinery, the slaughter house, and the smelter will make the sure profit. Again, most of the available analyses show a resulting high-sulphur crude which is already a drug on the market, and would be heavily penalized by existing refineries, if, indeed, it would be accepted. Economically, it seems that good financial results would only follow from operations sufficiently large to provide crude for an individual refinery, which preferably should crack the oil for the maximum yield of light distillate. Such a plant, together with equipment for the recovery of ammonia, will evidently require strong financial backing and excellent technical direction.

Time to Reverse the Old Adage

ON another page we publish a concrete, forward-looking suggestion relating to business and industry in this country after the war. Slow to enter the war, we have also been more deliberate than our European neighbors in anticipating post-war conditions, and preparing as far as possible to meet them.

We believe that no more constructive forces can be thrown into this work than those technical societies representing the industries that have undergone great expansion as a result of the war. The American Electrochemical Society already has decided to devote its next general meeting to a symposium on the future of our electrochemical industries. It seems quite likely that the American Chemical Society, the American Institute of Mining Engineers and the other great national engineering bodies would be of equally great assistance in shedding light on the problems of reconstruction, by scheduling post-war conditions as a subject for consideration at their next general meetings.

A New Turn in Flotation Litigation

THE latest turn of the kaleidoscope of flotation litigation has changed altogether the design and figure to which we had almost become accustomed as one legal decision followed another. With the decision of the Ninth Circuit Court of Appeals, reversing the decision of Judge Bourquin of the District Court in Montana, Minerals Separation is again put sharply on the defensive and the several defendants see the light of possible victory.

Important consequences flow from the latest turn in the litigation, not the least of which is the probability that the United States Supreme Court will again hear the case. But of more immediate satisfaction to the industry must be the clarification of several points that have been as cloudy as some of the scientific theories advanced to explain the process. In the first place, monopoly of the patent in suit is held to be limited to "a (specific) fraction of one per cent" of oil, and that fraction is 0.5 per cent. Second, the allegation that the use of more than one per cent of oil is an evasion of the patent monopoly, is completely upset, and a technicality is wiped out by a saner interpretation of the former testimony. The three judges were in concurrence save on the question of evasion in the use of more than one per cent of oil.

Sacrifices for the Steel Industry

NO PARTICULAR credit accrues to anyone who makes an ordinary sacrifice in these times, for the very fact that it is an ordinary sacrifice deprives it of any distinction. It is with no thought of suggesting that the steel industry deserves particular commendation for what it does that reference is here made to some little sacrifices it finds occasion to make. It is interesting, however, and perhaps stimulating, to mention a few items.

When the steel industry agreed to the "one price for all" dictum of President Wilson it made what was clearly a sacrifice, in the light of existing conditions, because it renounced the opportunity to accept commercial orders that were being offered at much higher prices than those set through the medium of the agreement. The extent of that particular sacrifice in the matter of prices has been gradually reduced until by this time it has really disappeared. It must not be forgotten that the agreement had in it some aspects of a compromise, in that the prices agreed upon, to form the basis of all sales except sales of commercial material for export, were undoubtedly somewhat higher than the Government would have insisted upon to apply in the case of its own purchases. Through the agreement the steel makers have received lower prices on commercial steel, and higher prices on war steel, than would otherwise have been the case. With the diverson of by far the major portion of the output to the filling of war orders the importance of this extra price on war steel is increased.

It is a very important sacrifice that the steel mills make when they ruthlessly cut off deliveries to old and valued customers for the purpose of diverting the maximum possible tonnage to the war work. The great majority of mills have made this diversion very willingly. It would be very unjust to the mills if this diversion were not made universal, for the slackers would thereby be making friends among commercial consumers who might therefore be disposed to patronize them in future, to the disadvantage of the mills which had renounced their trade when called upon to do so for the public good.

Of particular interest is the business sacrifice many steel producers have made in urging their customers to seek substitute materials. The most conspicuous example of this has been the tin-plate trade. The co-operation of that trade with the Government was, moreover, the earliest. Before the country actually declared war the tin-plate makers had pledged themselves to Secretary of Commerce Redfield that they would undertake to divert a maximum quantity of tin-plate to the packing of the perishable food products. That trade is the least stable of the industry's customers, its patronage being seasonal and dependent chiefly upon the magnitude of the crops Nature provides. For years the tin-plate mills have been endeavoring to build up custom by inducing manufacturers to employ tin-plate in place of other materials. As a rule these lines of consumption, which the mills have worked hard to build up, are the very ones that are now ruthlessly denied tin-plate, when the food products call for it, and are asked to find substitutes.

To stimulate the production of steel applicable to the filling of war orders the steel mills are indulging in many divergences from economical practice. They are using as scrap, material that has a high commercial value. For instance: Many mills are using sheet-bar crops as heavy-melting steel, when in the open market they would bring a price far above the heavy-melting steel basis. Shell-discard steel is being used in the same manner, when it could be rolled into finished products such as light rails, concrete reinforcing bars, bedstead angles and the like, at a very good profit. Valuable steel is thus used because the output of steel applicable to the filling of war orders is thereby stimulated. The case is not comparable with conditions in 1916 when with a large production of shell-steel mills were practically forced to melt a large part of their discard material.

Sacrifices of a new order are now being required, the authorities at Washington having begun instructing mills to close certain departments entirely so that supplies of war steel may be augmented. A notable instance of the early operations of this sort was the closing of the rolling departments of a new steel mill in the Cleveland district, the plant being asked to ship its entire ingot output to other plants which could use the crude steel in filling especially important war orders. The plant in question receives merely a price applicable to ingots and is deprived of the profit that would accrue from operating its rolls.

All these things are relative. With the greatest sacrifices that may be made by way of diverging from the most economical practice or the most profitable line of business, the steel mills have much larger earnings, even after the payment of Federal taxes, than have accrued in the best of peace times. That practice which might be denominated expensive are requisite is an argument that care should be exercised to maintain the set prices at such a level as to leave a safe margin. The profits, however, ought not to be permitted to be excessive unless it is intended to tax them still more heavily.

Readers' Views and Comments

The International Technical Affairs Information Service

To the Editor of Metallurgical & Chemical Engineering

SIR:—In spite of the greater efficiency of the individual American, the collective work of the Germans has been far greater in efficiency than the work of the Americans. I repeat, the *collective work was greater.*

The industrialists of this country have come to place more and more dependence upon information in print. To substantiate that statement it is only necessary to count the several hundred libraries operated by our leading industrial houses. The work of these several hundred industrial or technical libraries is extremely valuable, but these libraries, or the majority of these libraries, are working *independently.* The *collective work* of these libraries would aid the industrialist of this country and our allied countries tremendously.

France through the Societe de l'Encouragement pour l'Industrie Nationale, is pushing a national organization for a "technical literary reference bureau to aid the industrialist in the 'economic struggle' after the war." Belgium and Switzerland already have valuable establishments for the collecting and coördinating of scientific literary information.

America has recently formed, under the National Research Council, a Research Information Committee. The platform of this Committee was outlined in the April 1st issue of METALLURGICAL AND CHEMICAL ENGINEERING. In this Committee, so recently formed, there is, or might be, the beginning of a Directional Committee for the coördination of the resources to be found in the libraries of these several hundred industrial or technical libraries about the country, to say nothing of the valuable technical collections in the public, college and society libraries about our country and allied countries.

Believing that some sort of action is needed to follow up the excellent plea made in the editorial to be found in the March 25, 1915 issue of *Engineering News-Record* I have attempted to outline a few steps for the immediate organization of the "association of engineering librarians" called for in this editorial.

First, there should be appointed from the field of industrial libraries, a committee on coördination and coöperation. Second, this committee should earnestly study the most profitable ways of linking together these several hundred technical libraries. Third, the central office of this committee might well be allied with the central office of this newly formed Research Information Committee of the National Research Council, with a branch in all of the principal cities of this country and allied countries. Fourth, this organization should receive government recognition, as perhaps in no other way would certain of our close corporations be willing to open their facilities or unite with other facilities excepting under government orders. Fifth, a certain amount of government aid should be given this organization, as for example franking privileges, in certain operations and free distribution to this International Technical Affairs Information Service of its publications likely to be of value to this Service. Fifth and last, this International Technical Affairs Information Service should function, not only as a directional force in administering the coördinated resources, but it should also act as a large mail-order house of technical information for the industrial house not supporting a technical library.

Technical information is now being made, or put in print by the second. Every day lost in not harnessing this information through this proposed International Technical Affairs Information Service means so much economic loss to the many hundred technical men needing technical information as they never needed it before to say nothing of the excessive demand for technical information after the war. Why not organize this International Technical Affairs Information Service NOW?

Rapid Carbon Determination

To the Editor of Metallurgical & Chemical Engineering

SIR:—The following method for determining the carbon in steel has been used by me with considerable success, in the past few months. Johnson's method is used. The gas is taken from a high-pressure tank through a regular high-pressure reducing combination valve, comprising the diaphragm valve, followed by a needle valve. Both of these valves are kept open during the entire time that the apparatus is in use. The diaphragm valve should be so adjusted that it will admit a maximum of 15 lb. pressure to the train. I believe that the normal setting of these valves is between 15 and 25 lb. Between the valve and the train is a "Y" tube, one branch of which leads to the train, the other to a "U" tube filled with mercury, capable of accommodating at least 20 lb. pressure. This furnishes the "head" for the operation of the train. The gas passes successively through stick caustic, strong caustic potash solution, soda lime and calcium chloride. These reagents are contained in four towers of about 7 in. in height by 1½ in. diameter, with a shoulder at the top, taking a number five, two-holed rubber stopper. The jar containing the caustic potash solution should have about ¼ in. of mercury in the bottom to act as a seal in case the rubber tubing between the purifying train and the tank should break. These jars must be of fairly heavy glass with solid bases. They are filled and interconnected so that they occupy a space about 7 in. square. The stoppers are kept tightly in place by setting the apparatus on an 8 in. square board, placing another board of the same size, suitably perforated, on top of the stoppers, and clamping all together with long bolts running from top to bottom. On top of the top board is placed a gas header containing, besides the inlet, three gas valves, preferably those with long handles, as they are easier to manipulate.

The furnace cases are made of 3½ in. seamless steel tubing 1 ft. long. The ends are of asbestos wood.

The combustion tube is of fused silica, and the resistance wire is wound directly thereon for a length of about 9 in. The combustion tube is then placed in the casing and after the leads are secured, quick lime is packed tightly into the case until full. This furnace is very quick to heat, and uses less current, and lasts longer, than when the wire is wound on a protecting tube of alundum or is covered with clay. Moreover, fused silica combustion tubes lose their vitreous character, after some months of continuous use and must be discarded anyway. The furnaces are suspended, side by side, by means of metal straps from two pieces of strap iron, 1 in. by ¼ in., one at either end. These pieces of strap iron are bent in the shape of a square cornered inverted U, and are of such size and height from the table that the openings at the furnaces are a little below the level of the eyes. From the furnaces the gas goes to three sets of zinc-phosphoric anhydride tubes, and from there to the regulation Johnson absorbing bulbs.

The samples are all weighed beforehand into small sheet-metal troughs, closed at one end. These are kept in numbered compartments in a closed box until ready to run. The boats are made of nichrome ribbon. 1 in. by 13 gauge, 3½ in. long. They are simply bent into shape without welding. They are easy to make, last almost indefinitely, and the pigs do not stick to them, unless lead oxide is used. In weighing the absorbing bulbs, weigh them all against a common tare. It is convenient to make all the tubes weigh about the same amount.

Exclusive of the time required to weigh the samples, the writer has repeatedly run ninety carbons in eight hours. Three tubes are used for each furnace; one running, one weighing and one standing. Results on plain carbon steels usually check in the third decimal place.

Special Gold-Recovery Processes Practiced by the Early Portuguese and Spaniards

To the Editor of Metallurgical & Chemical Engineering

SIR:—In an interesting and well-written book, now very rare, entitled "Travels in the Interior of Brazil," particularly in the Gold and Diamond Districts," written by John Mawe, an English scientist and engineer and author of the "Mineralogy of Derbyshire," published in Philadelphia and Boston, in 1816, is a metallurgical reference which may have some import to the intrepid writers who are so readily, but not too lucidly, explaining the theories of flotation. On page 194, Mr. Mawe, in describing the methods practiced in the gold placer districts of Minas Geraes, to recover the gold from the black sands obtained in the major placer operations, says: "Some of the grains of gold were so fine as to float on the surface, and of course, were liable to be washed away in these repeated changes of water; to prevent which the negroes (slaves) bruised a few handfuls of herbs on a stone, mixed the juice in small proportions with the water in their gamellas (pans). Whether this liquid did in reality tend to precipitate the gold, I could not positively ascertain, but the negroes certainly used it with the greatest confidence."

Perhaps some of the flotationists can explain whether this primitive metallurgical application involves any of the present day principles of "surface tension," "ionization," etc., etc., which are invoked in order to justify, after the fact, the marvelous results of flotation as a metallurgical practice. Apparently the early Brazilian process "worked," but I have no information of the continued or wider application of the principle involved. It would be interesting if the delvers in the archives of metallurgy can confirm this observation of Mr. Mawe's.

On the west coast of Mexico, some years ago, I had as my mozo (servant), a very old Mexican miner, who in harmony with his antiquity, still lighted his cigarette with a flint and steel. He told me that in his youth in the mountains of Sinaloa he had been engaged in a gold mining operation in which the gold was refractory and difficult to recover. As an accessory to the metallurgical appliances and processes of that early day, which are more or less well known, it had been found effective in the treatment of this particular ore to crush it in the tahones (Chilean mills) with the leaves of a certain tree, and then to filter the slimes and water from the mill through charcoal, which charcoal was afterwards burned and an appreciable amount of gold recovered thereby. The tree, as it was described, was a species of oak and it was suggested that the leaves might have yielded tannic acid, or some compound related to cyanide. Since the advent into the metallurgical world of flotation, the idea has occurred that possibly this metallurgical practice of the early Mexicans was a crude precursor of flotation.

Is it not possible that these two instances of primitive metallurgy represent the early application of differential and selective adhesion of special solutions somewhat similarly as in the modern flotation processes and their modifications?

Influence of Temperature of Measurement on the Electrical Restivity and Thermo-Electromotive Potential of Solutes in Steels

To the Editor of Metallurgical & Chemical Engineering

SIR:—In your issue for November 15, last, you republished from a preprint of the American Electro-Chemical Society an article which I presented to that Society at its meeting in October. Your journal naturally reprinted it exactly as it appeared in the preprint, but proof of this article was never sent me before it appeared in the preprint. There were one or two minor mistakes in the title of the article, but these were not at all serious. There was, however, one serious mistake which arose from the fact that the printer in setting up the article omitted an entire line so that the meaning of the sentence was naturally lost. This sentence occurs near the top of the second column on page 592 of your journal. This sentence should read "would transform a maximum amount of electrical energy into heat, thus causing a maximum electrical resistivity."

E. D. CAMPBELL.

University of Michigan, Ann Arbor, Mich.

Western Metallurgical and Chemical Field

Conditions in Joplin-Picher Region

THE Joplin *News Herald* recently published interesting tables showing the production of blende, calamine and lead from the various camps in that region for the years 1916 and 1917. These tables furnish the basis of the following figures:

	Approximate Average Weekly Production of Blende for 1916	1917	Production for Week of Oct. 20, '17	Apr. 14, '18
Highest grade blende (basis 60% Zn)	...	.....	$75 per ton	$55 per ton
Price of zinc	...	...	7.9c.	7.0c.
Production:				
Oklahoma camps	2,080,000	5,920,000	8,463,000	7,323,890
Joplin	2,180,000	1,820,000	1,747,860	817,750
Webb City-Carterville	4,540,000	3,340,000	2,087,020	957,750
Duenweg	1,330,000	1,080,000	1,620,680	...
Total, including miscellaneous camps and calamine	14,150,000	15,700,000	18,205,210	12,701,760

The yearly figures show very plainly the rapid growth of the Oklahoma camps at the expense of the older fields; the Webb City—Carterville "sheet ground" district suffering the most. Many mills have been moved from the regions nearer Joplin to the richer Oklahoma camps, which have been able to continue much more nearly at its high rate, despite the low price of ore. The sheet ground mines are almost all down. From Duenweg to Oronogo there are only about a dozen mines and mills in operation where there were eighty a year ago.

Such conditions has provoked much discussion among the operators in the Tri-State field, resulting in resolutions calling for a tariff on imports of zinc ore amounting to two cents a pound. Their association has also appointed a committee to go to Washington in an attempt to interest the President directly in measures for their amelioration.

In the face of the rapid decline in the price of spelter occurring since the summer of 1917, the agreement between producers and the War Industries Board on a price for Grade A zinc brought a gleam of hope. This agreement was made in February under the usual stipulations as to uniform price, wages, production and speculation, and fixed 12 cents a pound for Grade A zinc, 14 cents a pound for plate zinc, and 15 cents a pound for sheet zinc thinner than $\frac{1}{2}$ inch. While the Joplin district produces but little of this material, still if the usual pre-war differential between sheet-zinc and prime western continued to exist, it would automatically place some sort of regulation on their product. Unfortunately this spread, which was 2.15 cents in August, 1914, has continued to widen, and the general zinc market has continued to slump.

The prospect of the government finding a larger use for that spelter which has hitherto been barred from Grade A owing to the presence of a little more cadmium than is permitted by the standard specifications has been carefully considered. It is not supposed that the specifications on Grade A will be lowered, but a higher cadmium zinc may be accepted on certain government work at a small discount from the Grade A price. If the smelters, on the other hand, could be induced to abandon the time-honored schedules, and pay an extra figure for cadmium-free ores, it is thought certain that considerable concentrates very low in lead, iron and cadmium could be selected and marketed for the production of Grade A. Meantime, with the increasing spread between prime western and higher grades, the margin available to cover redistillation costs becomes wider, but the resulting production of Grade A spelter affects the prosperity of the miner and millman but slightly.

The Pacific Kelp-Potash Industry

Several concerns are now engaged in the manufacture of potash from kelp on the southern Pacific coast, notably the Pacific Products Company, the Sea Products Company, and the Oceanic Engineering Corporation at Long Beach, the Lorned Manufacturing Company at Summerland, the Hercules Powder Company and the Swift Fertilizer Company at San Diego, California. The Bureau of Soils of the United States Department of Agriculture began the construction of an experimental plant for the extraction of potash from kelp last April at Summerland, California, and has operated since the latter part of August, under the direction of J. W. Turrentine.

The purpose of this plant is two-fold: To determine the cost of producing potash from kelp, but more especially to determine what byproducts can be simultaneously produced commercially. The product to date has been principally kelp char containing about 30 per cent K_2O, which has been produced incidentally in experimenting in methods for drying and distilling. This has found a ready sale at a very good price—practically paying the operating costs of the plant. There is of course a great demand for potash in the fertilizer and other industries, and for the iodine and other chemicals recovered as a by-product.

The plant has a capacity of about 150 tons per day, which can probably be increased to 200 tons after certain refinements in operation have been introduced. Apparatus is now being installed which will make possible the production of high-grade muriate and numerous byproducts. The present installation has cost approximately $100,000 and consists essentially of a self-propelled kelp harvester of a harvesting capacity of about 25 tons per hour, and a carrying capacity of 100 tons. The shore plant contains unloading devices and conveyors for delivering the kelp to storage bins, the latter of a capacity of about 300 tons; a drier house containing three direct-heat counter-current rotary kilns, 50 feet long by 5.5 feet in diameter, with furnaces; and the necessary vacuum evaporator, crystallizer and lixiviating apparatus.

Arizona Copper Company Increases Mill Capacity

During recent months, Mr. Arthur Crowfoot, mill superintendent for the Arizona Copper Company, has been able to increase the daily capacity of their mill at Morenci from 2800 to 4000 tons with virtually no important additions to the area of the plant. The increase has been effected by a revision of the flow sheet, necessitating the installation of two Symons disc crushers in the crushing division, the elimination of jigs, the installation of a new floor of tables, and the construction of additional large settling tanks. The last item of construction has just been completed, and includes very large Dorr thickeners for dewatering the tailings as well as the concentrates. This practice is necessary in order to conserve as much water as possible—fresh water is

pumped a distance of about six miles against a considerable head. Since it requires approximately 450 gallons of fresh water per ton of ore concentrated in order to sluice the tailings down the canon to their disposal, at least that amount of water must be added to the mill heads. A very interesting design of water meter after the order of the tilting tank washer has been installed in the concrete reservoir acting as a supply tank for the operations of the concentrator.

A particularly noteworthy feature of the concentrator is the installation of a dust-catching system in the crusher division. Gyratory, disc crushers and rolls for reducing 4000 tons of mine run to ¾-inch size are housed in and connected to an exhaust fan, which delivers the dusty air to a centrifugal dust catcher. The solids are sprayed with water while circulating through the catcher, and the separation is so nearly complete that little dust can be observed in the exhaust. The atmosphere in the crushing division itself is very clear, and the installation may be said to have solved the dust problem in the dry-crushing plant.

A 100-ton experimental mill is being installed in a building formerly used as a crushing plant before the new main hoisting shaft was sunk. In this plant methods will be studied of concentrating low-grade sulphides containing in the neighborhood of one per cent copper, which the company possesses in very large quantity. The first trials will be on floating the finely-ground eject from a Marcy mill, with table cleaning of the flotation tailing.

Portland Company Closes Colorado Springs Plant

The exhaustion of bonanza mines is often referred to as the reason why a large expansion in metallic production does not follow war prices. Unfortunately gold production is hindered rather than helped by high prices, but the continuing exhaustion of known deposits is as patent as those of other metals. Witness the closing of the Colorado Springs plant of the Portland Gold Mining Company, of which a final clean-up was made in April. This mill was built to treat high-grade ores only, and is useless now that the high-grade ores of the Cripple Creek District are being exhausted. In its sixteen years of life it has extracted gold at an average rate of over two million dollars per year, but during the past years there has been a constant decrease in the tonnage of high-grade ore shipped, owing to a lessened production of the district, this doubtless accentuated by the shortage of efficient labor and the high cost of fuel, powder, timber, and other necessary supplies.

The Portland Company foresaw the probable shutdown of the Colorado Springs plant and provided room for the treatment of their own and custom high-grade ore when constructing their new Independence Mill, expecting to transfer the necessary machinery and workmen from the older plant. The Independence Mill, by the way, was primarily designed to treat monthly about 42,000 tons of low-grade ore from dumps and old workings, the latter estimated to amount to about three million tons. Eventually all milling-operations of the Portland Company will doubtless be done at this new mill, which is modern in every respect, since the Victor Mill, built eight years ago as an experimental plant to handle ores too low in grade to bear shipment, was constructed at the mine on an unfavorable location. It has earned net profits more than double its original cost, however, while the net earnings of the Colorado Springs plant amount to several times the original cost of that plant.

By-Product Coke Plant at Pueblo

Two batteries, each of 60 Koppers ovens, are nearly completed at the Minnequa plant of the Colorado Fuel and Iron Company at Pueblo, Colo., and have the distinction of being the first of their kind west of St. Louis. The operations of the by-product coke department will be in charge of H. B. Carpenter as superintendent. The ovens are of the regenerative type, with vertical flues, and are 40 feet long, 10 feet high, and 19 inches wide, with a capacity of 12½ tons of coal, which charge produces 8½ tons of 16-hour coke. This installation can therefore carbonize 70,000 tons of washed Trinidad coal per month, making 46,000 tons of coke and distributing daily 600,000 cubic feet of by-product gas at a pressure of five pounds per square inch to the open-hearth department, heating furnaces and soaking pits.

The hot coke will be pushed into a transfer car, taken to a brick quenching station and drenched by a large spray of water, and thence to a coke wharf, down which it slides. A rotary feeder then delivers it to a 42-inch conveyor leading to a screening station; the large coke goes to the blast furnaces, and the breeze and dust are burned in Cox stokers under steam boilers.

Tar from the primary coolers, gas mains and tar extractors is separated from ammonia liquor in a tank by specific gravity, and loaded into tank cars for shipment. A complete plant for the recovery of by-products from the oven gas has been installed. Ammonium sulphate, benzol, toluol, xylol, solvent naphtha and naphthalene will thus be separated and purified for the market.

New Picric Acid Plants

Contracts have just been completed by the Ordnance Department for the establishment of two large picric acid plants. Sites have been selected at Little Rock, Arkansas, and Brunswick, Georgia, and the construction work will be rushed at once by the contractors. Men and material for the buildings are all ready on the ground at Little Rock, and it is expected that the plant will be in operation by September.

The Everly M. Davis Chemical Corporation has been awarded the contract for the Little Rock plant, the construction of which will cost approximately $1,000,000.00.

A larger plant is to be constructed by the Butterworth-Judson Co., of New York City, at Brunswick at a cost of nearly $7,000,000.

These are the first government-controlled picric acid plants to be established in this country. The sites were chosen in the South after a most careful investigation of housing, labor, transportation facilities, and strategical conditions. In choosing the Little Rock location, the Ordnance Bureau was able to take over a number of buildings which will be used as part of the plant.

The location of these plants in the South, in addition to the two nitrate plants now located at Sheffield, Alabama, makes that section of our country preëminent in the manufacture of chemicals by the Government for production of explosives.

Water Power Hearings Closed

Joint Water Power Committee of Congress Begins to Draft Bill

THE record of the special hearings held on water-power development was closed May 18 after listening to the news of Secretaries Baker and Houston, who, with Secretary Lane, comprise the commission proposed in the Administration bill. A formal statement by William H. Onken, Jr., editor of *Electrical World* was submitted and added to the record.

Statement of Secretary of War Baker

Secretary Baker commented on the bill as originally submitted by the three secretaries and also on the effect of the proposed amendments subsequently offered. The latter he said were introduced for the purpose of clarity. His own view is that the terms of the franchises provided for in the "administration" water-power bill shall be definitely limited to fifty years. On this point his testimony was as follows:

"We have to decide at the outset whether a fixed term is to be used, at the end of which there is an end of the rights of the licensee, or whether we are going to spread the investment of any licensee over an indefinitely prolonged period under proper safeguards. If it be determined that a single term of fifty years is to be the principle of the bill, then any investor must, whether you provide it in the bill or not, amortize the investment in fifty years. That means that the consumers during the fifty years will have to pay by that much a higher rate than they would have to pay if they covered in their rates merely obsolescence and replacements and did not sink the entire original cost during the period of the grant. If the primary object is to secure a minimum rate to the consumer, the course of having consecutive terms would be the proper course.

"The purpose of this bill was to have a fifty-year term, and at the end of the fifty-year term the government was to have the three options of either taking over the property, granting it to a new licensee or regranting it to the original licensee or his successors in interest. The intention of the bill was to make those three options identical, so far as the financial obligation was concerned. If the government took it over, it would pay X dollars; if it granted it to a new licensee, the new licensee would pay X dollars; if it regranted it to the original licensee, it would ascertain and fix, as a new starting point for his net investment, X dollars, the same number of dollars in each instance. The purpose of the bill, as originally drawn, I think—and certainly as clearly shown by the amendment—was not to sink and amortize the original cost during the first term, but to carry that investment—depreciate it so that at any particular period of renewal it represented the actual value—to carry that forward as a continuing asset in the licensee, either to be repaid to him by any other licensee or by the government or to be regarded as his investment at the beginning of the new license period.

Secretary Baker Favors Fifty-Year Term Without Privilege of Renewal

"Now, my own judgment, my very strong preference, is for the first of those courses, to fix an absolute term and to allow the government not to have a system of equities built up against it at the end of that term. If that were done, it would cost more to the consumer clearly, but if it is intended to do that, it ought to be so clearly done that when the first term or first license does expire, there will not be any doubt that the government has a right to expect the licensee to have protected himself by amortization during the period.

What Constitutes Fair Value

Secretary of Agriculture Houston, in discussing net investment as defined in the amended measure, said that the original draft of the bill provided for recapture of the water power development at fair value. In suggesting the term "net investment" as the basis for payment it was thought it would not be susceptible to any misunderstanding or misinterpretation inasmuch as the term was specifically defined. However, it is inconceivable that there should be any unappropriated surplus to deduct from the original cost as required in the measure (see *Electrical World*, March 16, page 581), and for that reason he suggested the following amendment to the clause on "net investment" as defined in the amended measure or to "fair value" as understood in the original draft:

"That out of surplus earnings, if any, accumulated in excess of a specified rate of return upon the net investment of the licensee in any project or projects under license the licensee shall establish and maintain amortization reserves, which reserves shall, in the discretion of the commission, be held until the termination of the license or be applied from time to time in reduction of the net investment. Such specified rate of return and the proportion of such surplus earnings to be paid into and held in such reserves shall be set forth in the license."

Should the government at the end of the fifty-year period take over the project that sum would be deducted from the original cost. Whether or not to make amortization within the fifty-year period compulsory was a question of policy for the committee to decide. To do so would mean higher rates for the electric service during the life of the franchise, which the utility has a perfect right to exact.

Statement of William H. Onken, Jr.

The question of waterpower development has been so fully discussed before various congressional committees during the past six years that it is difficult to contribute anything new to the voluminous testimony already forming part of the record. However, it may be pertinent to observe that notwithstanding all the light that Congress has received on the subject, we still lack legislation due to the failure of legislators themselves to agree.

In view of the fact that electricity is now more and more a necessary part of our social and industrial life, and that its uses for purposes of irrigation and for the manufacture of nitrogen for explosives has become a matter of trmendous import in our national defense, might it not be well to abandon all theories of ideal legislation and adopt some practical measure as speedily as possible?

The Value of Cheap Electricity to Industry

As typifying what hydroelectric development means to a community and at the same time showing the enormous waste caused by non-development, the case of Niagara Falls is unique. The mighty cataract alone, not including the rapids is capable of developing five million horsepower. This, if sold at the modest rate of twenty dollars a horsepower, or what is equivalent to 3 mills per kilowatt-hour would yield a revenue of one hundred million dollars per annum. This amount of money is qual to a 5 per cent return on an investment of two billion dollars, and yet what government would spend that stupendous amount of money to reproduce the spectacle? It is true, we have power companies which develop a fraction of the power available, but the roar of Niagara is as nothing compared to the din of the industries set in motion by the electricity generated from a fraction of the water in the falls.

At Niagara Falls are located the greatest electrochemical industries of the world. More would be located there if more power were available but because of the shortage of power many have been forced over into Canada, and still others have gone abroad. These electrochemical industries are of vast importance to this nation. They started at Niagara Falls and for the greater part they still remain, handicapped as they are for want of electricity. On these electrochemical industries depend numerous other industrial establishments throughout the country, valuable in time of peace, but infinitely more valuable in times of war.

First of the electrochemical enterprises in point of electric power requirements is the aluminium industry. Next in line come the ferroalloy compounds including ferrosilicon, ferrochromium, ferromolybdenum and so on. The next electrochemical industry in point of size is devoted to the manufacture of calcium carbide used chiefly in the production of acetylene. Artificial abrasives which constitute the basis of all modern grinder work are also manufactured at Niagara Falls, as well as caustic soda, chlorine in the form of bleaching powder and other chlorine products; chlorates which are used in the match industry, in the textiles, for the manufacture of oxygen and in other chemical operations; sodium used in the textile industries as a bleaching agent, and which is still more important in the manufacture of sodium cyanide; phosphorus, carbon disulphide and numerous other products absolutely indispensable to industry today.

More Value in Industries Created than in Water Power

It is needless for me to continue further along this line to impress you with the vast importance of electrochemical products to other industries, ignoring entirely the fixation of atmospheric nitrogen for fertilizer and for munition work. I merely cite the case to show how infinitely more important are the industries depending upon electricity than the electric generating system itself. It is of interest to note in this connection that the combined income from the sale of electrical energy of the Niagara Falls Power Company and the Canadian Niagara Power Company for 1917 was a trifle over $3,000,000. I have no statistics showing the output of electrochemical products manufactured from the electricity sold for that purpose nor the cost of the numerous other products which in their fabrication involve electrochemical products. However, the citations given indicate the stupendous value of these products as compared with the cost of the electricity used.

Annual Meeting of the American Society For Testing Materials

The twenty-first annual meeting of the American Society for Testing Materials will be held at Atlantic City June 25 to 28, 1918, with headquarters at the Hotel Traymore.

A provisional program has been announced as follows:

Tuesday morning, June 25.
- Minutes of the 20th annual meeting.
- Annual report of the Executive Committee.
- Reports of technical committees.
- Announcement of election of officers.
- Miscellaneous business.

Tuesday afternoon, June 25.
- Reports of committees on wrought iron, cast iron, and testing.
- A Simple Type of Brinell Testing Machine for 500 kg. Load. A. V. de Forest.
- A New Type of Brinell Machine. J. G. Ayers, Jr.
- Effect of Moisture on the Strength of Aircraft Fabrics. G. B. Havens.
- Transverse Testing under Non-Uniformly Distributed Load as Applied to Airplane Wing Ribs. I. H. Cowdrey.
- Sumner Elastic-Limit Recorder. J. L. Jones and C. H. Marshall.

Tuesday evening, June 25.
- Annual address by the President, followed by a reception.

Wednesday morning, June 26.
- Reports of committees on steel.
- Cast Steel Anchor Chain. James French.
- Grain Growth of Cold Wrought Metals. D. J. McAdam, Jr.
- Changes within the Critical Range of a Given Steel: From Ac_1 to Ac_3. J. G. Ayers, Jr.

Wednesday evening, June 26.
- Topical discussion on coöperation in industrial research, by Dr. Henry M. Howe, Dr. John Johnston, Dr. A. D. Little, Dr. Charles L. Reese and Mr. Frank E. Gorrell.

Thursday morning, June 27.
- Reports of committees on preservative coastings and non-ferrous metals.
- The Valuation of Zinc Dust and a Proposed Method of Analysis. L. A. Wilson.
- Topical Discussion on "Season and Corrosion Cracking of Brass: Its Prevention and Means for Testing the Tendency Thereto."

Thursday evening, June 27.
- Joint session with the American Concrete Institute on cement and concrete.
- Reports of committees and papers on cement and concrete.

Friday morning, June 28.
- Reports of committees on lubricants and lime.
- The Standard Saybolt Universal Viscosimeter. W. H. Herschel.
- Internal-Combustion Engine: Lubrication and Lubricants. P. H. Conradson.
- The Variable-Pressure Method of Determining the Viscosity of Oils. E. C. Bingham.
- Mechanical Sifting of Cement. D. A. Abrams.
- Effects of Grading of Sands and Consistency of Mix upon the Strength of Plain and Reinforced Concrete. L. N. Edwards.

Friday afternoon, June 28.
- Reports of committees on ceramics and refractories.
- The Necessity for Inspection and Testing of Refractory Brick. C. E. Nesbitt and M. L. Bell.
- Silica Cement. R. J. Montgomery.
- An Abrasion Test for Gravel and Stone for Road Purposes. H. H. Scofield.
- Sampling of Deposits of Road Stone and Gravel. L. Reinecke.

Friday evening, June 28.
- Reports of committees on fireproofing, coke, waterproofing, electrical insulating materials, shipping containers, and rubber products.

Minerals Separation vs. Butte & Superior

Opinion of District Court in Favor of Plaintiff Reversed by Court of Appeals—Contentions Repudiated Regarding Non-Effective Oils—Minerals Separation Process Not Infringed by Use of More Than One Per Cent Oil

ON MAY 13, 1918, the United States Court of Appeals for the Ninth Circuit, at San Francisco, filed its opinion in the Minerls Separation-Butte and Superior Case.

Each of the judges wrote an opinion, Judge Ross and Judge Hunt, in concurrence, giving the majority opinion, while Judge Morrow wrote an opinion concurring in part and dissenting in part.

The opinions were rendered in a review of the decision of Judge Bourquin, of the District Court of Montana, which was given Aug. 25, 1917, and from which the defendant, the Butte and Superior, appealed.

Judge Bourquin's opinion, it will be recalled[1], was very strongly in favor of the contentions of Minerals Separation, and as Mr. Canby pointed out in his comprehensive review of the American litigation up to that time[2], Judge Bourquin's opinion practically reëstablished the original claim 12, so wide a scope did he allow Patent 835,120. He found that the defendant, in increasing its use of "oil" to an excess of one per cent, had done so by the use of certain oils which Judge Bourquin said were inert and useless, or even harmful, "having no more effect than so much milk or other useless substance," while maintaining the pine oil at about the same quantity which they had been using prior to Jan. 7, 1917, the date of the U. S. Supreme Court decision. Judge Bourquin thus discriminated between what he considered effective and non-effective oils, and decided that the defendant could not escape infringement by the addition of the latter.

In the presentation before the San Francisco Court the experts for Minerals Separation, among others, performed an experiment by way of demonstration to show that these petroleum oils which defendant was using were not frothing oil and would not produce a "froth." But unfortunately for their contention, and in absolute contradiction to the statements being coincidentally read from record by plaintiff's counsel, a really excellent froth was produced, so that the judges must have been more impressed by what they saw than by what they heard, since all three of the judges repudiated this distinction as to effective and non-effective oils.

Using More Than Fraction of One Per Cent of Oil Is Not Infringement

Even Judge Morrow, whose opinion is the dissenting opinion of the Court, says—"I am of opinion that the use of an oil or oily liquid in defendant's separation process in a quantity *not* 'amounting to more than a fraction of one per cent on the ore' is within the express terms of Claims 1, 2, 3, and 12 of plaintiff's patent, and is an infringement of such patent. But I am of the opinion that the use of an oil or oily liquid amounting to more than a fraction of one per cent on the ore is not within the terms of Claims 1, 2, 3, and 12 and is therefore not an infringement upon plaintiff's process . . . ."

We have been so long accustomed to think of the Minerals Separation patent (835,120) as being the use of one per cent of oil, that possibly few of us realize just what the patent really does mean, as decided by the U. S. Supreme Court and now interpreted by the Court of Appeals in San Francisco as its meaning, and that is that "a fraction of one per cent" does not mean every fraction of one per cent, but only that fraction of one per cent constituting "critical proportions."

Since the claims of a patent can not be broader than the discovery or invention it would seem clear that the claims of this patent, 835,120, referring to "a fraction of one per cent" should not be so broadened as to include a greater percentage than that embraced in this discovery. If this is so, Minerals Separation's exhibit of Higgins' report of the experiments as to the effect of reducing "oil" in the Cattermole process, clearly shows that it was at about half of one per cent that the effect constituting the discovery, was first apparent.

What Constituted Invention in M. S. Process?

In the argument before the U. S. Supreme Court there took place a colloquy between Justices McReynolds and Pitney, and counsel for Minerals Separation, which Judge Ross quotes in full, and to which Judge Hunt refers in these words:

> Again, when counsel had a colloquy (quoted in the opinion of Judge Ross) with the Supreme Court, the guiding thought evident in the mind of the inquiring Justices was to stamp precision upon the point when *invention in the process* began to appear. With apparent definite purpose of meeting the interrogatories plaintiff told the court that "invention" began to come when in the descending uses of percentages of oil as small quantity as five-tenths of one per cent was used, and was first present when three-tenths and two-tenths of one per cent was used. Of course a court should cautiously consider a response often quickly made by counsel in answer to questions put from the bench lest an injustice may follow by attaching undue weight to an isolated argumentative answer, but in this matter we are earnestly trying to gather the scope and accurate meaning of the expressed thought of the court. We may therefore refer to the fact that the exact position of the plaintiff as to the invention was called for not once but twice, not generally nor indirectly, but positively, simply and unequivocally.

The colloquy above referred to has appeared in journals reporting the proceedings before the Court, so that we need not quote it again from Judge Ross's opinion, of which it forms an important part, and although one can well imagine the chagrin of counsel in having such a colloquy forming so large a part of the Court's opinion, that is as to space occupied, and as shown in the above quotation from Judge Hunt's opinion, as to its determining force in interpreting the opinion which the U. S. Supreme Court intended to express, and, also, undoubtedly in determining the opinion of the U. S. Supreme Court itself, through the information which the colloquy gave to them, the actual fact as to the scope which the claims to Patent 835,120 would be entitled is in reality determined by the plaintiff's statement of the discovery as set forth in the Higgins' report, above referred to. One can not but assume that the U. S. Supreme Court, even without such a colloquy, would have decided as it has done, and that it was indeed such an appreciation of the scope of the discovery which led the Justices to make the inquiries.

[1]Met. & Chem. Eng., Sept. 15, 1917.
[2]Eng. & Min. Jnl., Dec. 1, 1917.

Three Points at Issue

Notwithstanding the very voluminous record in the case, and the many angles presented through the several hearings in the various cases up to this hearing, there was presented to the court in San Francisco practically only three points for decision. These were as follows:

First. What had the Supreme Court decided as to the bounds of the invention, and does the use of oil in proportions greater than the so-called "critical proportions" violate any rights of the patentee?

Second. Does the evidence in the Butte and Superior case contain anything which was not before the Supreme Court, of such a nature that that Court would have been led to a different conclusion if it had been presented in the Hyde case?

Third. What is the purpose and effect of the so-called "disclaimer" filed by the plaintiffs after the opinion of the Supreme Court in the Hyde case was handed down?

As to the first of these, Judges Ross and Hunt are of the opinion that the Supreme Court meant what they said as to "critical proportions" and that they did not mean that Claims 1, 2, 3, and 12 included all percentages of "oil" up to one per cent. "A fraction is one thing, every fraction is a different thing," says Judge Ross, and continuing, adds: "It is obvious, we think, that if the Supreme Court had meant to extend the scope of claims * * * of the patent to one per cent of oil on the ore as is here contended it would not have said anything about any fraction of one per cent. Certainly there would have been no necessity for doing so and certainly the use of such specific language as it employed without a purpose cannot be justly imputed to that great tribunal." Then after copious quotations from the decision of the Supreme Court, in the Hyde case, Judge Ross continues: "Nothing, it seem to us, can be clearer from the foregoing quotations from the opinion of the Supreme Court, than that it did not intend to extend the monopoly of the patent in suit to the use of one per cent of oil on the ore; for it, in effect, thereby distinctly declares and adjudges that the discovery of appellee "experimenters" only rose to the dignity of *invention* when they ascertained that the desired results could be and were obtained by the use of five-tenths (½) of one per cent of oil on the ore."

As to the second of the three points, above referred to, had they found sufficient new evidence to warrant them in so doing, they might have gone outside of the Supreme Court decision, even to the extent of finding the process of the patent anticipated, but this they did not do.

As to the third point, that is purely a legal technicality as to certain alleged undue delays in entering disclaimers as to the claims which were declared to be invalid by the Supreme Court, in the Hyde case, those claims in the patent calling for simply "a small quantity" of oil. The Court of Appeals found that there had been no illegal delay.

"The decree appealed from (in the District Court) must be and is reversed and the case remanded with directions to the Court below to so modify its decree as to accord with the opinions of the majority of this Court, the appellant to recover its costs on this appeal."

Annual Meeting of the New York Section American Institute of Mining Engineers

Symposium on the World's Iron Ore Resources—Election of Officers

THE annual meeting of the New York section of the A.I.M.E. was held in New York, May 28, 1918. Minor changes were made in the by-laws and the following officers were elected for 1918: Chairman, A. H. Rogers; vice-chairmen, Forest Rutherford, H. C. Parmelee; treasurer, Frederick T. Rubidge; members of executive committee, J. E. Johnson, Jr., and P. G. Spilsbury.

The meeting was a symposium on the iron ore resources of the world in relation to national economic conditions after the war. E. C. Harder, Waldemar Lindgren, C. M. Weld, A. C. Spencer, H. Foster-Bain and Sidney Paige each addressed the members present on different phases of the subject.

The Brazilian Iron Situation

E. C. Harder of the University of Minnesota presented a paper on the Brazilian iron situation.

He stated that Brazilian iron ores would now be offered in European and American markets had not the necessary capital been diverted for war purposes. It is considered equally certain that they will be a prominent factor in the reconstruction of Europe. The Brazilian iron-ore field takes rank among the five great iron-ore districts of the world, the others being (1) the Lake Superior district of the United States, (2) the Lorraine ore field of northern France and Southern Germany, (3) the northern Sweden deposits and (4) the ore fields of Oriente, Cuba. The Brazilian field is the greatest known undeveloped iron-ore district in the world, and its aggregate tonnage is variously estimated up to three billion and a half. The largest deposit contains at least five hundred million tons, and deposits containing from ten to fifty million tons are numerous.

The iron-ore district is about 100 miles square and is in the State of Minas Geraes, its center being about 250 miles north of Rio de Janeiro, with which city it is connected by the Central of Brazil Ry. A new railroad, the Victoria a' Minas, designed for ore transportation, is now under construction from Victoria.

Two types of ore occur. The more important interbedded variety gives a high-grade hard ore averaging 69 per cent iron, low silica, and less than 0.02 per cent phosphorus, and a low-grade soft ore averaging 60 to 68 per cent iron, depending upon the amount of silica, and from 0.01 to 0.07 per cent phosphorus. The other type is a product of weathering and is of lower grade but ranges up to 65 per cent iron and a phosphorus content of from 0.1 to 0.3 per cent.

Previous to 1910 practically all these deposits had been owned by Brazilians, but soon after that they gained publicity and were rapidly acquired by English, American, French and German interests. The English and American holdings are more important and include practically all of the deposits which will derive benefit from the new railroad. The German and French interests are tributary to the old railroad, which is scarcely able to handle its present manganese business.

It is still questionable as to just what use these ores will be put. Brazil itself does not at present offer a market and possesses no coal deposits suitable for iron manufacture. This lack of coal has been the great factor in retarding the development of the iron deposits; it necessitates exporting this great national resource of Brazil, which fact has caused the Brazilian government much concern but is now accepted as inevitable.

England has imported annually during the last few years about 4,500,000 tons of iron ore from Spain, about 1,000,000 tons from northern Africa and about 800,000 tons from Scandinavia. It is hoped that the Brazilian output may eventually reach 10,000,000 tons annually which will be sufficient to supply England's demands for foreign ores and leave a surplus for the United States and for other countries.

In the United States the Brazilian ores will probably be found to be a very desirable furnace mixture for low-grade ores and for more refractory ores. They will doubtless also be used in the Bessemer furnaces to replace the gradually decreasing supply of domestic Bessemer ores.

The great fleet that will be necessary to carry the iron ore to the United States and Europe will be used to carry return cargoes to Brazil. This will offer cheap transportation for such products as coal, iron and steel manufactured articles and cement. It will aid greatly in the industrial development of the country and perhaps eventually it may be possible to operate small iron and steel plants in Brazil at a profit to supply the domestic needs of iron and steel products.

Swedish Iron Ore Reserves

Dr. Lindgren discussed the Swedish and Norwegian iron-ore deposits. He stated that the deposits in the central part of Sweden were divided into three groups. The first group consisted of high-grade magnetites imbedded as lenses in limestones and dolomites. There are small quantities of these ores and they are of no importance for export. They are used in Sweden in the production of high-grade iron. Associated with the magnetites are banded hematites which are also of only local interest. The apatite iron ores of central Sweden are of importance as the reserves amount to 100,000,000 tons and a considerable exportation of them is carried on. The total reserves of central Sweden amount to 122,000,000 metric tons. These deposits are of minor importance to the world as a whole.

The Lapland deposits in northern Sweden at Gellivara and vicinity were stated to be of the greatest importance as the ore reserves totalled 1,150,000,000 metric tons and are concentrated in a comparatively few large deposits. The iron ores are rich in phosphorus, only a small proportion being as low as 0.05 per cent phosphorus. The bulk of the ores average 58 per cent iron and from 1.5 to 3 per cent phosphorus. The deposits are opened by a railroad which extends from the Baltic to the Arctic ocean, and, while the severe climatic conditions interfere with operations, a production of 7,000,000 tons per annum was made according to the last reports. Under pre-war conditions one-third of this ore was shipped to England and two-thirds to Germany. The iron ores of Norway are of less importance and total 280,000,000 metric tons. As much of this ore is low grade its exploitation is dependent upon the success of concentration methods.

Importance of Cuban Iron Ore

A description of the Cuban iron ore deposits was given by C. M. Weld. He estimated the total tonnage at 3,000,000 tons. They form surface blankets of great extent, averaging from 15 to 25 ft. thick and ranging from 1 to 70 ft. in thickness. There is no overburden. The ore is high in hygroscopic and combined water, the total of water reaching 35 per cent. The phosphorus content is below 0.02 per cent and the ores contain 0.5 to 1 per cent nickel and 1.5 per cent chromium. The steel made from the ore has valuable properties. The deposits are of first importance.

The Iron Ores of China

The iron ore deposits of China were briefly reviewed by H. Foster Bain, of the U. S. Bureau of Mines. Mr. Bain said that while it is still too early to make complete estimates of China's resources enough is known to warrant approximate figures. Stated in the briefest terms the approximate probable tonnage of the known deposits suitable for modern uses is 402,000,000. Of this the Chinese government retains title to about one-third, Chinese companies claim somewhat less than one-third, and Japanese or Sino-Japanese companies have over one-third. These estimates do not include all of the iron ore as doubtless there are deposits still to be discovered and in the smaller bodies suitable only for native furnaces or far in the interiors there is not improbably 300,000,000 tons additional.

Mr. Spencer gave the following figures for the reserves of Europe and Africa in metric tons:

Continental France, not including Alsace-Lorraine, 2,000,000,000; Spain and Portugal, 730,000,000; Austro-Hungary, 200,000,000 to 300,000,000; Greece, 100,000,000. Algeria, 150,000,000.

Fixed Price for Toluol

The War Industries Board has had its attention called to the fact that in some instances excessive prices are now being demanded for toluol when sold under release for other than military purposes.

When Government action or demands in any branch of trade results in material increase in price, it is incumbent upon the Government to protect other users of the commodity by seeing that the price to the trade does not advance to a point in excess of the price paid by the Government.

In accordance with this the War Industries Board has extended the Government price to cover all toluol which will be released for non-military purposes.

The Government price is:

Carload lots in tank cars.....$1.50 per gallon
Any quantity in drums.....$1.55 per gallon

No release will be granted for shipment of toluol where a price in excess of the above is asked and all releases granted for other than military uses will be stamped:

"Released only upon condition that price does not exceed $1.50 per gallon in tank cars; $1.55 in drums."

The War Industries Board will be glad to have its attention directed to any demand for higher prices.

The President's Readjustment and Reconstruction Commission

A Vital Suggestion Relating to the Establishment of American Industry on a Sound Basis After the War—What Foreign Countries Are Doing—Necessity for Taking Care of Our Present Industrial Expansion

BY WINGROVE BATHON,
Washington Representative, McGraw-Hill Co., Inc.

PEACE will come some day. In the meanwhile American industry is doing nothing whatever in an organized way to prepare for the necessary readjustment. On the other hand, England and her colonies, France, Italy, the Teutonic empires, the Far Eastern countries, and the Latin-American countries have begun to prepare for readjustment and reconstruction.

What must we do?

This article is for the purpose of suggesting the immediate creation of an agency to deal with the situation which will confront American industry at the end of the war, to gather facts now, to make plans now, to educate now, and to lead the industries of the country in the victories of peace when the right time comes.

In detail, this is to suggest that a great service would be done the American people, and perhaps all of the free peoples of the world, in view of the resources of the United States which must be drawn upon for a long period by the whole world after the war, if the President of the United States would appoint forthwith a commission, to be the President's own commission, to prepare for after-the-war problems. Such a commission should not be hampered by legislative enactments of Congress as to powers upon which it might be difficult for Congress to agree; not curbed and controlled by Government appropriations or the fear of lack of them. It should nevertheless be established under the Government sanction of an executive order, and should be assisted by the creation of an Advisory Council of Government officials and possibly the chairman of some committees of Congress. Many executive officials and legislators are themselves too busy with the work of the war to lay aside burdens of today to deal with after-the-war problems. Their assistants and associates should be used. As to the main commission, it should include not only leaders in industry of all forms taken from the ranks of private endeavor, but it should include leaders in labor, leaders in education, and leaders in every other endeavor which enters into industrial effort. Such a commission should report only to the President and should take as much of its inspiration from his leadership as he has time to give from the conduct of the war with which he is charged by the Constitution. Such a commission might very well include in its appointees the following:

Suggested Personnel of the Commission

E. H. Gary, President of the American Iron and Steel Institute; Samuel Gompers, President of the American Federation of Labor; Arthur N. Talbot, President of the American Society of Civil Engineers; C. P. Main, President of the American Society of Mechanical Engineers; E. W. Rice, President of the American Institute of Electrical Engineers; Sidney J. Jennings, President of the American Institute of Mining Engineers; Wm. H. Nicholls, President of the American Chemical Society; F. J. Tone, President of the American Electrochemical Society; A. G. Doan, President of the American Machine Tool Builders' Association; H. A. Wheeler, President of the Chamber of Commerce of the United States; P. H. Gadsden, Secretary of the American Electric Railway Association and Resident Washington Member of the Electric Railway War Board; S. G. Williams, President of the Highway Industries Association.

In addition there should be the presidents of some of the various national organizations occupied with production and manufacture in the lumber, leather, rubber, textile, glass and other great industries of the country; as well as perhaps the president of the Farmers' Grange, the president of a great railroad, the president of a great shipping company, the president of a great educational institution, the president of a great insurance institution, and perhaps the president of the American Bar Association and the president of the American Medical Association; but, in any case, and by all means, even if only to assure reports from abroad, the following representatives of American business in other countries:

A. V. Edwards, Secretary of the American Commercial Club of Argentina, Buenos Aires; Charles E. Lydecker, Secretary of the American Chamber of Commerce of Brazil, Rio de Janeiro; James R. Morse, Secretary of the American Chamber of Commerce in China, Shanghai; George M. Cassatt, Secretary of the American Chamber of Commerce in England, London; Charles H. Sherrill, Secretary of the American Chamber of Commerce in Paris, France; J. B. Stetson, Jr., Secretary of the American Chamber of Commerce in Italy, Milan; C. B. Parker, Secretary of the American Chamber of Commerce for Mexico, Mexico City; Preston M. Smith, Secretary of the American Chamber of Commerce for Spain, Barcelona; and Theodore R. Yangco, Secretary of the Chamber of Commerce of the Philippine Islands, Manila.

In Washington, the peace-time industries of the country are now being placed upon a war basis in a gradual manner. There has been time for a gradual "turning over" in the further organization of the war which has been proceeding steadily month by month. But when the industries of the country have been fully

placed upon a war-time basis, when supplies of labor, sources of material, reserves of capital and the markets for production have all been altered to meet war needs, it will be impossible to place industry back upon a peace basis gradually without danger of disaster second only in importance perhaps to the actual loss of the war.

To meet the danger there must be organized preparation, such as is now proceeding in all of the countries at war except the United States, and these suggestions are being made to set forth a working plan as a nucleus for discussion and action.

Similar Work Done by Foreign Countries

The facts and the prospects for the future are being discussed and acted upon in almost every country of the world except this. Literally thousands of books, pamphlets and other writings have been produced in foreign countries to educate the people along these lines. More than two years ago there was created in Great Britain a Reconstruction Committee, which has since become an agency of the British Government, the work now being in charge of Dr. Christopher Addison, a Minister in the British Cabinet without portfolio; and more than two hundred sub-committees plentifully supplied with experts are now engaged in solving British after-the-war problems.

The detail of what has been done in Great Britain and the other countries previously mentioned, and some suggestions as to what should be done toward readjustment in this country, will be offered in later articles.

After the war, because of accelerated thinking, we can secure the adoption of ideas that otherwise would not be acceptable, or would be acceptable only after a very lengthy educational process. Therefore we have an opportunity now, for, in addition to such obvious readjustment and reconstruction work as the orderly reintroduction to industry of returned soldiers, the development of export trade, and the use of our productive capacity for our industries expanded by war needs, we can use, now, the opportunity to secure the adoption by the people generally of economic theories such as the husbanding of our exhaustible natural resources, such as coal and other fuels, iron, timber, etc., and we can also bring about now the adoption of policies which will insure the perpetual renewal of even the so-called inexhaustible natural resources, such as the soil and its products.

Proposal for an Advisory Council

An Advisory Council for the suggested commission should be selected from those who are especially charged with the conduct of affairs vital to the industrial, commercial, transportation, labor, financial and educational worlds. Realizing the demands made by the war on chief cabinet officers, it should not be expected that they should serve actively on such a Council, although in one or two cases, such as that of William P. G. Harding, the Governor of the Federal Reserve Board, principal officials, rather than those second in command, ought to be selected. In the case of legislators, many chairmmen of Senate and House committees are also too much occupied with war legislation to deal now with after-the-war problems. Officials of executive departments on such an Advisory Council should be charged not only with the duty of giving advice and outlining governmental policies of the present and possible policies of the future, but should detail to the service of the commission experts in their own departments. In the following list, strict order of precedence and rank in the Government is not followed, but such an Advisory Commission or Council should include:

Frank Lyon Polk, Counselor for the Department of State, for all international contact;

F. M. Simmons, Chairman of the Senate Committee on Finance, for contact on future Government revenues and taxes;

Claude M. Kitchin, Chairman of the House Ways and Means Committee, for contact on future Government revenues and taxes;

Duncan U. Fletcher, Chairman of the Senate Committee on Commerce, for contact on legislation affecting commerce;

Thetus W. Sims, Chairman of the House Committee on Interstate and Foreign Commerce, for contact on legislation affecting commerce;

Gilbert M. Hitchcock, Chairman of the Senate Committee on Foreign Relations, for contact on future international legislation;

Henry D. Flood, Chairman of the House Committee on Foreign Affairs, for contact on future international legislation;

John Bassett Moore, Vice Chairman, United States Section, International High Commission, for contact with international law, patents, trade-marks, etc., in Latin America;

John Barrett, Director General, Pan-American Union, for Latin American contact in detail;

William P. G. Harding, the Governor of the Federal Reserve Board, and Charles S. Hamlin, President of the Capital Issues Committee, and Sherman Allen, Treasurer of the War Finance Corporation, for contact on finance;

E. R. Stettinius, Assistant Secretary of War, for contact in industrial war production; and Rear Admiral Samuel McGowan, Paymaster General of the Navy, for contact on industrial naval production;

Maj. Gen. E. H. Crowder, Provost Marshal General, for contact on reintroducing returned soldiers to industry;

William H. Taft and Frank Walsh, Chairmen, War Labor Board, for contact with war labor problems and activities;

John A. McIlhenny, President, Civil Service Commission, for contact on Government employment;

Carl Vrooman, Assistant Secretary of Agriculture, for contact with the soil and its agricultural products;

Edwin F. Sweet, Assistant Secretary of Commerce, for contact with the Census and other Bureaus dealing with commerce;

William B. Colver, Chairman of the Federal Trade Commission, for contact with the coming administration of the Webb Act which permits combinations for foreign trade and for contact on unfair practices under the Newlands Act;

F. W. Taussig, Chairman, United States Tariff Commission, for contact on material now being gathered by Commission on after-the-war problems;

Raymond B. Stevens, Vice Chairman, United States Shipping Board, for contact on tonnage available after the war;

Herbert Hoover, United States Food Administrator, for contact on food licenses during reconstruction period and possible repeal of laws;

H. A. Garfield, United States Fuel Administrator, for distribution of coal and oil and possible repeal of laws during and after reconstruction period;

Walker D. Hines, Assistant to the Director General of Railroads, for contact with transportation and terminals after the war;

A. Mitchell Palmer, Alien Property Custodian of the United States, for final disposition of enemy-owned plants and other property;

Bernard M. Baruch, Chairman of the War Industries Board, for contact on sources of supply of raw materials and finished products;

Walter S. Gifford, Director of the Council of National Defense, for contact on reviving less essential industries;

Vance C. McCormick, Chairman, War Trade Board, for contact on licenses for imports and exports after the war;

Executive Secretary (when named) of the Water Power Commission of Cabinet Officers which is about to be created;

Daniel C. Roper, Commissioner of Internal Revenue, for contact on collection of excess profits taxes, etc.;

Charles D. Walcott, President, National Academy of Sciences, for Government contact with the sciences;

Charles F. Nesbit, Division of Military and Naval Insurance, for contact on personal insurance problems and defectives on his rolls who are returned soldiers;

Philander P. Claxton, Commissioner of Education and Secretary of the Federal Board for Vocational Education, for contact on educational statistics and statistics on defectives;

George Creel, Chairman, Committee on Public Information, for assistance and contact in educational work.

It is respectfully submitted that this is no mere list of names. Broadly speaking, it is an analysis of the industrial war organization of the United States, and a reading of the suggested contacts will show that the work of these officials, and that of their departments, bureaus and associates, will be just as vital to the solving of the after-the-war problems as it is vital to winning the war now. The two problems cannot be separated. All national contacts today are international. We think and move in terms of world-wide importance.

Industrial Changes Created by War

After four years of war, England has found it necessary to tear up and move to France between fifteen and twenty per cent. of her main line tracks. If the war lasts a long time, if there is not iron enough, if there is not steel enough, if there is not labor enough, if there is not constant maintenance, something like that might happen in this country. Then there will be need for actual physical reconstruction in this country, as there is abroad, instead of need merely for readjustment. Plans for such possibilities must be made now. Again, it is estimated that we shall have within a year forty-five to fifty million tons of steel-ingot-producing capacity and probably one hundred per cent greater finishing-machine-producing capacity than we had in 1913, in which year we were obliged in many lines to go abroad for a market for our surplus production. What plans are in the making for our surplus production after the war? Again, it is estimated that we shall have, with what we now have, 15,000,000 tons in merchant ships available after the war. What definite trade routes from American ports to the other ports of the world are being thought out?

No Central Government Agency Ready with Information Desired by Industry

The biggest American business which has been built up abroad has been in machine-finished steel products, such as talking machines and music machines, cash registers, agricultural machinery, adding machines, sewing machines, etc. Plans must be made to introduce these special products. One company now represented in Washington desires to open an office at Rio de Janeiro; another desires to send 600,000 tons of shipping to Australia next year. Is there any governmental agency or semi-governmental agency in Washington to offer encouragement or authoritative advice? No. What is being done to divert to American ports the rehandling business previously done in Europe, such as the bringing of rice from India, to reclean it, regrade it, and reship it; what is being done to hold for the United States the rubber now coming here to avoid two trips through the submarine zone which formerly went to England; what is being done to hold for the United States the business in tin which formerly went to England and Holland from Bolivia; what is being done to hold for the United States the business in coffee which originally went almost entirely to Europe, at which time we paid for the longer freight haul and commissions in London, Hamburg and Bremen, and much of which now comes to this country?

An Advisory Council such as has been outlined in this article, working with the proposed President's Readjustment and Reconstruction Committee or Commission, could answer these questions, if answers are in existence; and if not, could place industry through the Commission in a position to meet such problems as have been suggested, and a thousand more. The United States Tariff Commission is one of the few governmental agencies which is avowedly gathering data for after-the-war problems. The Federal Trade Commission, the Department of Commerce, and the War Trade Board are also collating some information. But there is no apparent co-ordination of these efforts, such as there is in England and other countries. The next article in this series will deal with what is being done in that respect in England.

Chemical Engineers Meet This Month

The summer meeting of the American Institute of Chemical Engineers will be held at Gorham and Berlin, N. H., Wednesday, June 19th to Saturday, June 22nd.

The following papers will be read and discussed:

The Human Element in the Mill, by Hugh K. Moore

Maintenance, Construction and Organization of Sulphite Mill, by Walter H. Taft.

The Seeding Method of Graining Sugar, by H. E Zitkowski.

The Manufacturer and Fuel Situation, by Wm. H Booth.

War Pyrotechnics, by G. A. Richter.

Food Conservation by Edw. Gudeman.

Chemical Stoneware and its Properties by A. Malinovszky.

Symposium on the Coal Tar Industry: Expansion of the Coal Tar Industry in the United States by F. E Dodge.

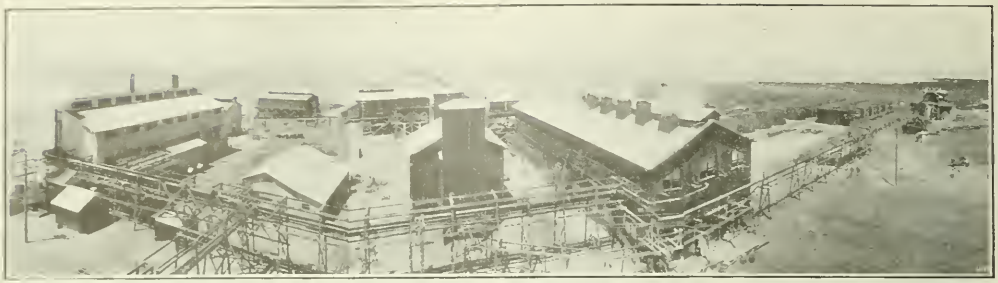
Expansion of the By-product Industry of Coal and Water Gas Plants in the United States by W. M. Russell.

Manufacture of Phenol by A. G. Peterkin.

Multiple Tangent System for the Manufacture of Sulphuric Acid by L. A. Thiele.

The following plants of the Brown Company will be visited under the leadership of Mr. Hugh K. Moore: The sulphite mill, the largest in the world; the saw mill and photographic department; the Cascade paper mill; the chemical plants, including electrolytic and caustic plants; fibre tube mill, carbon tetrachloride plant, chloroform plant and hydrogenated oil plant.

A joint meeting with the local section of the American Chemical Society will be held on Wednesday evening at the Mt. Madison House, Gorham, N. H. A unique feature of the program will be an entertainment by the employees of the Brown Company. Headquarters will be at the Mt. Madison House, Gorham, N. H.



The California Kelp Operations of the Hercules Powder Company

An American Industry Developed as a Result of a Demand for Acetone for Use in Munitions. An Example of American Chemical Engineering and Research Applied to a Pioneer Project

THE giant kelp of the Pacific Coast has provided a good deal of material for dreams and almost a hurricane of gossip, but detailed information of the industrial production of potash or anything else from this source has been scarce. Long lists of the botanical names of the various species of kelp have been published, and alluring notes on the K_2O content of dried material, showing amazing variations, have been recorded; but when engineering details were given, it has often happened that the information was inspired by some promotion scheme. On the other hand, time and again the possibilities of this kelp in industry have been made evident and our curiosity has grown alert to discover the actual progress of industrial research in the matter.

A little over a year ago Mr. H. L. Glaze of Los Angeles predicted in an article in this journal[1] that the crowning achievement along kelp-potash lines would be that of the Hercules Powder Co. on the bay at Potash, near San Diego. Other concerns have built plants and some seem to be succeeding, but the Hercules works at Potash are the largest of all and we are now in a position, thanks to a number of gentlemen connected with the company as its officers, to give a record of its achievements in research and industry.

It is interesting to note that the growth of this great undertaking and the working out of the processes have followed along different lines from those of others working in the same field. It was designed and built because the Powder Company had a contract to furnish the British Government a large quantity of powder, but the British Government did not want the Powder Company to compete against it for the large quantity of acetone required for the purpose. To complete the contract a new source of acetone had to be found and the Hercules people immediately began an exhaustive study of kelp with this in view. The results were very promising and in February, 1916, ground was broken for the works. By Fall of the same year the plant was completed and running. Thus the need of acetone was the main reason for establishing the plant, while the potash and many of the chemicals which have been produced may be classed as subsidiary products, although large in tonnage.

[1]Potash from Kelp in Southern California, April 1, 1916, p. 355 et seq.

Extensive Research Required

A great amount of research has been done by the company in the development of this undertaking; indeed a large number of both research and control chemists have been required from the start. In providing harvesters it has demanded the highest order of engineering skill and ingenuity to design or to adapt equipment to uses previously unknown to meet the unusual problems. New questions in practice arose daily and these had to be solved immediately or the operation of the plant would be interrupted.

As the fruit of intense research and untiring engineering application, the plant is now producing in substantial quantities, muriate of potash 95 to 98 per cent pure and practically free from sulphate, acetone that tests

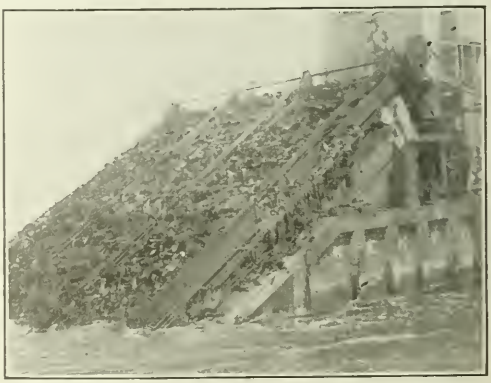


FIG. 2. HARVESTING KELP

better than the stringent specifications of the British Government, iodine U. S. P. and ethyl acetate meeting all the usual commercial specifications. In addition to all these well known chemicals, the works are producing ethyl propionate and ethyl butyrate on a scale never before approached. These latter solvents are especially interesting as amyl acetate substitutes on account of the efforts which the U. S. Government is now making to conserve acetate of lime.

General Features of the Project

The plant shown in the general view, Fig. 1, is located on the bay at Potash, near San Diego. Over $5,000,000 has been spent in its construction and operation, and it covers about 30 acres. It uses about 6000 boiler horsepower and approximately 1000 men are employed, including from 75 to 100 at sea on harvesting work. Chemical control involves from 1500 to 2000 tests daily. The research staff numbers from 15 to 20 and this work is housed entirely separate from the control laboratories. The company is cutting about three-fourths of all the kelp cut on the Pacific Coast. In 1917 it averaged about 24,000 tons per month.

Harvesting the Kelp

This is the first step in the process. The designing of harvesters began as soon as the plant was started. Although about 100 patents had been taken out by other inventors, no really efficient design of harvester for large-scale work existed at that time. The system which has proved satisfactory consists in a combination of harvesters, barges and tugs. Fig. 2 shows a harvester in operation, with the freshly cut kelp carried up from the water by moving screens. From the screens it passes through macerators and thence into the hold of the harvester vessel and from this point it is pumped through a pipe boom to a barge, as shown in Figs. 3 and 4. The cutters or harvesters are ocean-going boats and stay out at sea all the time, while the barges carry the macerated kelp back to the wharf where it is pumped from the holds into fermenting tanks which are shown in the general panorama in Fig. 1, and also in Figs. 6 and 7. Pumping kelp was a problem at first but it was solved by a model of a Goulds rotary pump. Foreign matter such as bolts, nuts, etc., brought in with the kelp are removed by electromagnets before the pumps are reached.

FIG. 4 BARGE BEING FILLED WITH KELP

Harvesting consists in cutting the plant about six feet below the surface of the water. It has actually been found that this treatment improves the growth and stand of the beds to such an extent that they may be cut over about every ninety days. The area cut at present extends from Pt. Conception south to the Mexican line.

Fermentation of Kelp Pulp

After it is pumped to the redwood tanks shown in Figs. 6 and 7 the kelp is diluted to a certain point and allowed to ferment under the correct temperature conditions. This unit is believed to be the largest in the world and comprises over 150 tanks of 25 ft. diameter, holding 50,000 gal. each. Each tank is equipped with hot-water coils for temperature regulation and compressed-air pipes are arranged to provide the proper agitation. Railroad tracks are laid between the batteries of tanks, and here Brownhoist locomotive trains are operated to load material upon the bridges which connect the tanks. Fermentation takes from ten days to two weeks and sometimes more. The organic acids, acetic, butyric, propionic, etc., are formed during the process and, by the addition of lime, their respective calcium salts are produced. These go into solution together with the potash and other soluble salts which are

FIG. 3. PUMPING KELP FROM HARVESTER TO BARGE

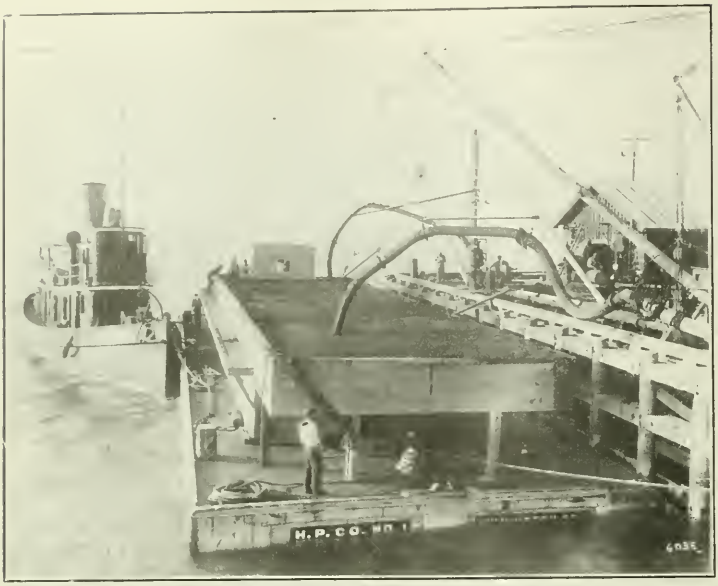

FIG. 5. DISCHARGING A BARGE-LOAD OF KELP

released as the fermenting process breaks down the cells of the kelp.

Separation Processes

After the fermenting period the resultant liquor is screened to remove undigested matter, following which the solution is allowed to settle. It is then filtered. The clear liquor contains potassium and sodium chlorides and the calcium salts of various fatty acids, but chiefly of acetic, butyric and propionic. The filter press building is shown in Fig. 8 with the Oliver press in the background and the two Kelly presses to the fore. The residue left from screening is still waste, and is discharged as refuse.

Evaporation is conducted in quadruple effect Kestner vacuum evaporators, shown in Fig. 9. They are operated with exhaust steam at a maximum pressure of 5 lb., and with a vacuum of about 26 inches. Triplex plunger pumps are used at this point. The principal trouble in evaporation has been to keep the evaporator tubes free from scale. After evaporation to a certain point the liquors are allowed to crystallize, and the first product to come to the top is a mixture of the calcium salts of the fatty acids, which from its nature has been named "taffy." This taffy is removed and subsequently made into high-grade solvents. The next body to crystallize is calcium acetate, which contains some potash, and at this point the liquor is removed and cooled. Then the bulk of the potash comes down as 95 to 98 per cent pure potassium chloride. A view of the lower floor of the crystallizing house is shown in Fig. 10. The salt chambers and cone bottoms of the cold kettles are shown on the left and the hot kettles to the right. Fig. 11 shows the upper floor of the same building with the same arrangement: cold kettles on the left and hot kettles on the right.

Later Treatment of Crystallized Products

As stated above, the taffy, which is obtained as the first product, contains salts of fatty acids of the acetic series. It has been found possible, after considerable research, to make from this such products as ethyl butyrate, ethyl propionate, etc., and methyl-ethyl-ketone as well as higher ketones, on a considerable scale. This is a noteworthy development inasmuch as it opens up a new source of supply of high-grade solvents which heretofore have been made entirely from calcium acetate. In fact, the solvent situation has been so serious that the U. S. Government has placed restrictions upon the use of calcium acetate. This development of an entirely new supply of solvents will surely be welcomed by important chemical industries which depend for their

FIG. 6. TANK FARM FOR FERMENTATION OF KELP

FIG. 7. INTERIOR VIEW OF TANK

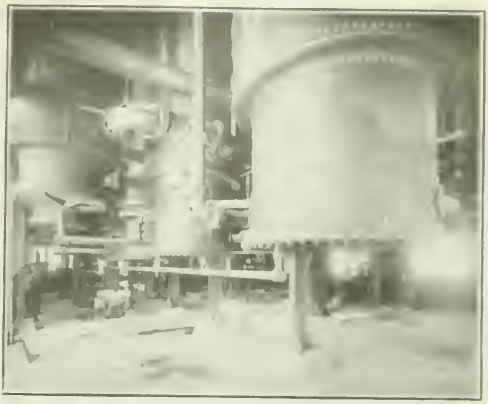

FIG. 6. LOWER FLOOR OF EVAPORATOR PLANT

existence on a constant supply of standard solvents such as ethyl acetate, amyl acetate, etc. Indeed, it seems probable that for the first time in the history of chemical industry, a practical supply of ethyl butyrate and propionate is placed within reach. These esters, being almost identical in physical characteristics, more particularly in regard to their boiling points, solvent power, freedom from residual odors, etc., form very desirable substitutes for amyl acetate and other solvents of a like nature.

The next product, calcium acetate containing some potash, is used to produce acetone, while the residue from distillation contains potash and the iodides. This is further separated with the production of high-grade iodine and more potash (chloride), which, like the product of the first crystallization, runs above 95 per cent in purity and is practically free from the sulphate. All potash is carried from the salt chambers to the centrifugal building by side-dump buckets, where they are elevated to Tolhurst centrifugals. After centrifuging the crystals are dried in steam-jacketed rotary dryers and then sacked and are ready for shipment.

The Finished Product

A feature of singular interest is the purity of these kelp products. It is fair to say that these results have become possible only after long and arduous research; that the separations of the organic esters are difficult and that the work involved great experimentation. The field was new and processes and apparatus had to be established and designed *de novo* to meet some conditions while standard apparatus had to be radically rearranged to meet others. Indeed, these difficulties presented themselves at every step in the organization of the plant. Ethyl acetate and ethyl anhydride are also made, the latter being used to produce cellulose acetate for non-inflammable aeroplane dope.

The potash is all used for chemical purposes, owing to its unique purity, and there is not enough of it to supply this demand. The total quantity of the pure product is not great enough to be considered seriously for fertilizer purposes. There are, however, a number of residues produced which contain potash which amount to quite a tonnage and these offer interesting and attractive possibilities in which fertilizers are to be considered. Research is in process in regard to these residues. To the chemical trade, however, the products of special interest are the 95-98 per cent KCl and the organic solvents.

Everything points to the permanency of this industry.

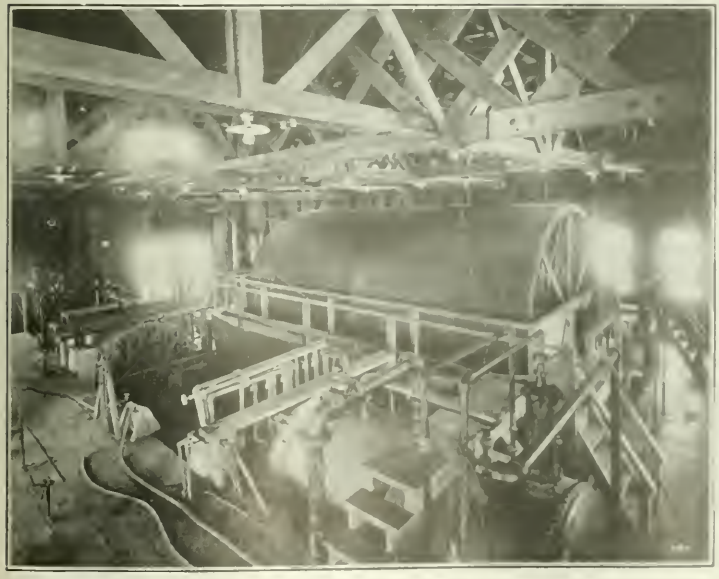

FIG. 8. INTERIOR OF FILTRATION PLANT

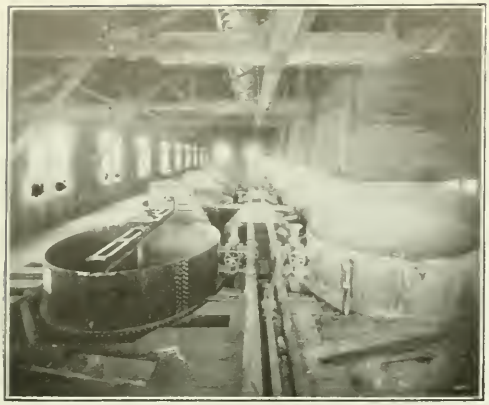

FIG. 11. UPPER FLOOR OF CRYSTALLIZING HOUSE

The statements published as to the amount of potash, iodine and other constituents of kelp and as to the quantity of the available kelp itself have, as a rule, been greatly exaggerated. It is doubtful if this will ever be a really important source of fertilizer potash for which, although the quality is not important, an immense tonnage is required. At this establishment, the promise of permanence lies in the quality of its products. After the war demand ceases, the chemical industry will surely want the KCl for the production of potash salts; and the solvents have long been needed.

The company plans to have a comprehensive exhibit showing the various stages of the work and samples of its products at the Fourth National Exposition of Chemical Industries which will be held in New York City next September.

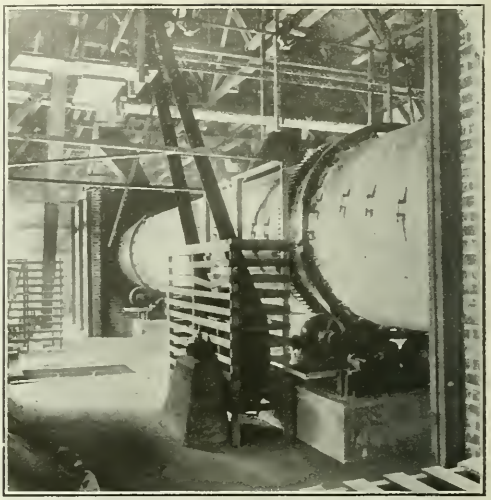

FIG. 12. ROTARY DRYER FOR POTASH

The British Nonferrous Metal Industry Act.—This act is characterized by *Commerce Reports* as marking another step in British preparations for trade after the war of almost equal importance with the Imports and Exports Bill. Its effect cannot be predicted owing to the broad discretionary powers vested in the Board of Trade. All houses carrying on the "business of winning, extracting, smelting, dressing, refining or dealing" in more than 25 tons of zinc, copper or lead quarterly, or more than 5 tons of tin, nickel or aluminium, metal, scrap, or ore must be licensed. The Board of Trade may refuse licenses to houses to which any one of six conditions apply, one of which, the most inclusive, is: "That the company, firm or individual is by any means whatever, subject, directly or indirectly, in the conduct of their or his business to enemy influence or association." Companies must recall all unregistered stock carrying voting power in the management. The applicant for license must furnish detailed information as to the names and nationalities of all officers, shareholders and members, the location and management of foreign branches, and declarations as to any connection with enemy firms dealing in nonferrous metals and ores.

The act is unusually broad and will have a large influence in determining post-war conditions in Great Britain.

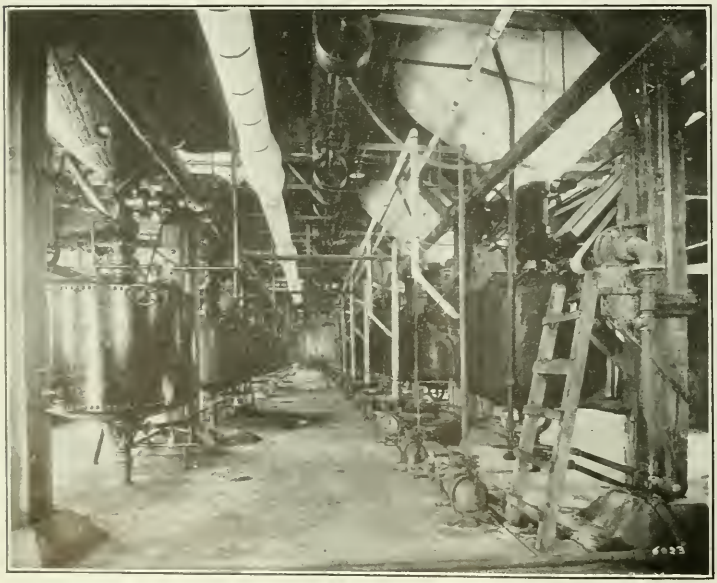

FIG. 10. LOWER FLOOR OF CRYSTALLIZING HOUSE

Electrochemistry and National Economy*

By Colin G. Fink

THE American Electrochemical Society considers itself very fortunate indeed to have been afforded the opportunity of undertaking this most interesting and highly instructive trip through the Appalachian South. What we have already seen more than convinces us that the Appalachian South is rapidly developing into one of the leading industrial centers of the world. We electrochemical engineers look upon Muscle Shoals as the new Niagara, the Niagara of the South! What constitutes an electrochemical industrial center? What are the essential requisites? What are the raw materials necessary for the production of that long list of metals, alloys, carbides, fertilizers, explosives, abrasives, lubricants, solvents, refractories, disinfectants, electrodes, and gases for cutting and welding? The first essential is an abundant supply of cheap power—power to be had in large blocks for 24 hours a day and 365 days a year! Cheap power is almost always synonymous with water power—and of this the Appalachian South has been supplied by nature in gracious abundance. In the state of Tennessee alone, according to the estimates of Prof. J. A. Switzer, there are available almost one million horsepower. In other words, Tennessee alone has enough power available to foster an electrochemical industry twice the size of that existing at Niagara Falls today!

Nitrogen-Fixation Plants in the South

When our Government decided to establish the nitrogen fixation industry in this country and considered the various localities suitable for the electrochemical production of those most vital compounds, ammonia and nitrates—without which we could neither feed our populace nor defend our borders—our Government, after due deliberation, most wisely decided to erect the "air saltpeter" factories at Muscle Shoals, Alabama. Therefore as regards the supply of cheap water power in the Appalachian South there is no doubt. Careful surveys have reported a vast abundance. In this connection it is gratifying indeed to note that the United States Chamber of Commerce, comprised of 500,000 business executives from every state and territory in the country, unanimously adopted resolutions calling on Congress to make provisions for harnessing the millions in water horsepower that are now going to waste.

The development of our water-power resources is of prime national economic value. It means the saving of coal and oil, which though most abundant here in the South are nevertheless exhaustible, and once used can never be replaced. It means the saving of railroad equipment now used for the transportation of coal and oil; it means the saving of a long list of valuable chemical products now burned and wasted under thousands of boilers; and it means the saving of millions of dollars in labor. The water power generated in the Province of Ontario, Canada, has reduced coal consumption between 5,000,000 and 6,000,000 tons per annum. Under fairly efficient working conditions it requires from 2 to 6 pounds of coal to generate power equivalent to one horsepower-hour. Think of the tons and tons of coal represented by the available water power of this country, which is estimated by the Geological Survey at 32,000,000 hp. minimum potential.

The By-Product Value of Coal

The electrochemist looks upon the vast coal resources of the Appalachian South as intended for purposes of greater economic value. The coal reserves of a single state, West Virginia, have been calculated at 150,000,000 tons. The southern coal makes the best coke, and very valuable by-products are thereby conserved. Alabama is second largest coke-producing state in the country. Tons of coke are shipped from the South to Niagara Falls and there heated in contact with sand in large electric furnaces that produce temperatures that are higher than can be attained in any other way. A beautiful crystalline product is obtained, carborundum, a silicon carbide, an abrasive which has found world-wide application. Another important electrochemical product largely dependent upon Appalachian coke is calcium carbide. This was first made by Willson at Spray, North Carolina, by mixing ordinary limestone and coke and heating to very high temperatures in the electric furnace. Calcium carbide is the source of acetylene, which is used in conjunction with electrolytically produced oxygen in the oxy-acetylene torch for steel welding and steel cutting. You are all familiar with this time and labor-saving device! Calcium carbide furthermore serves as the "raw material" in the electrochemical manufacture of cyanamide, which the Government will soon be turning out by the ton at Muscle Shoals. It is a very efficient fertilizer. Another and very recent by-product of calcium carbide is acetone, consumed in large quantities in the manufacture of explosives. There seems to be no end to the list of compounds and products of inestimable worth that are all primarily derived from Appalachian coke.

Aluminum and Abrasives from Bauxite

The South has been most strikingly favored by nature in the line of raw materials for electrochemical products. Next in importance to her coke resources are her extended deposits of bauxite, the basic mineral from which that metal of many uses, aluminium, is derived. The aluminium industry of this country ranks among the very first and consumes almost as much in kilowatts as all the other electrochemical industries put together. There are but four states in the whole country that have been mining bauxite in commercial quantities—Arkansas, Georgia, Alabama and Tennessee. In 1917 these states turned out 400,000 metric tons of bauxite, which is 12 per cent more than the world's bauxite output of the year 1910. The Aluminum Company of America has a large metal-producing plant at Maryville, Tennessee. This appears to us as a very wise move. Why ship bauxite by freight hundreds of miles away? Why not make the metal near the source of the raw material? It requires 2 tons of bauxite for one ton of aluminium metal.

Bauxite is also used for the manufacture of aloxite and alundum, artificial emeries of great hardness and uniformity which are made in electric furnaces at Niagara Falls. The artificial abrasives, alundum, aloxite and carborundum have practically replaced imported emery and corundum. These electric furnace abra-

*Presidential Address, 33rd General Meeting American Electrochemical Society, Knoxville, Tenn., April 30, 1918.

sives have virtually revolutionized the machine shops, doubling and trebling their output.

An electrochemical industry which is most typically American is the electrolytic copper refining industry. Over 75 per cent of the copper consumed today is purified and refined by electrochemical methods; it is of the highest attainable quality, exceeding in purity Sterling silver. The largest electrolytic copper plant in the world is located at Canton, Maryland, with an annual production of 720,000,000 pounds. The modern electrical industry with its dynamos and motors, its telephone, telegraph and wireless and its countless electromagnetic devices would be helplessly crippled if we were to deprive it of electrolytic copper.

In the electric steel industry the United States likewise leads the world. The quality of electric steel surpasses that of the best crucible steel. Next to Minnesota and Michigan, Alabama is the largest iron-producing state in the Union. Over 50 per cent of the iron ore reserves of the U. S. are located here in the South.

Closely linked with the electric steel industry is the ferro-alloy industry—Ferromanganese, ferrosilicon, ferrochromium, ferrotitanium and others. Ferrosilicon and other ferro-alloys are electrically made by the Southern Ferro Alloys Co. at Chattanooga, Tennessee. Electric ferromanganese is made by the Southern Manganese Corporation at Anniston, Alabama.

Deposits of manganese occur in many parts of the United States but are most abundant in the Appalachian and Piedmont region, Virginia and Georgia being the largest producers. Silicon is derived from quartz rock and sand. Titanium is derived from the mineral "rutile." For many years the sole producer of rutile in this country has been the American Rutile Company whose plant is at Roseland, Virginia. Rails made of steel to which ferrotitanium was added during the process of manufacture, are less liable to breakage and are 40 per cent more durable than are ordinary open-hearth rails. Another electric titanium alloy is cuprotitanium, containing 10 per cent titanium and 90 per cent copper. This is extensively used in making sound castings of copper and bronze.

Carbon bisulphide is a solvent upon which the rubber industry is very much dependent. Formerly it was made by long tedious and expensive processes. Today all carbon bisulphide is made electrochemically. The raw materials are charcoal and sulphur. The great sulphur states of the world are Louisiana and Texas. The combined output of these two states exceeds not only that of all other states put together but that of all the rest of the world. One of many wells of the Union Sulphur Company discharges 500 tons of sulphur per day.

Modern Versus Earlier Processes

If we arrange the electrochemical industries according to the number of factories and the total power consumed, both in this country and abroad, we find that the electrolytic alkali and chlorine industry ranks fourth in the list. What a long array of interesting and important products have been developed and turned out by the ton by this industry: caustic soda and bleach, chlorine gas, sodium metal, disinfectants and peroxides and a series of valuable compounds! The basic raw material is common salt, NaCl, and it is interesting to note that Virginia is sixth largest salt-producing state in the country. The electrochemist takes this salt, dissolves it in water and passes a current of electricity through the solution. How simple is this electrolytic method compared to the old fashioned process of producing alkali and chlorine, according to which you had to start out with pyrites or sulphur, oxidize this to sulphuric caid, add this acid to salt thereby liberating hydrochloric acid; then taking this acid and treating it with manganese peroxide to "free" the chlorine gas; the sodium sulphate, obtained by adding the sulphuric acid to sodium chloride, was dried, mixed with coke and limestone and transformed by heat into calcium sulphide and sodium carbonate; finally the sodium carbonate was dissolved in water and boiled with lime producing sodium hydrate or alkali. We certainly need not emphasize that electrolytic alkali spells economy. Think of all the labor and power that is conserved!

One of the most recent achievements of the electrochemist is the commercial production of electrolytic tin. Unfortunately, outside of Alaska, our country has no large tin deposits. The electrolytic tin refining plant at Perth Amboy derives practically all of its ore from Bolivia. However, during recent years our government has undertaken an earnest search for tin in this country and it is gratifying to read the recent report of the U. S. Geological Survey on promising deposits developed in the Kings Mountain and Lincolnton districts, North Carolina and in Rockbridge County, Virginia. So that it seems if we are to have any tin industry at all it will be here in the south.

Truly, nature has been most lavish with her treasures here in the South and the electrochemical engineer finds in this region, rich in natural resources, water power, iron, coal, phosphates, manganese, aluminium, titanium, quartz, salt, copper, pyrites and limestone, the most ideal localities for the founding and fostering of important electrochemical centers.

Instructors Wanted for Engineers Training School

The Government proposes to establish immediately at Camp Humphreys, Va., a training school for replacement troops of the Engineer Corps. These men will be given intensive training to fit them for the special service required in connection with the various engineer units in the service. A complete school in which all the trades as identified with the engineer units of the Army will be taught by means of short intense courses.

As this school will have an ultimate capacity of approximately 30,000 men, many instructors will be required and an appeal is made to the qualified men beyond the draft age who are willing to volunteer their services and enlist in the Engineer Corps as instructors in this school. The requirements are: a thorough knowledge of the following branches—machinists, blacksmiths, wheelwrights, carpenters, concrete foremen, electricians, dynamo experts, miners, painters, riggers, sheet metal workers, foundrymen, automobile and motor trucks, gas engine men, draftsmen, photographers and general foremen of construction.

Full particulars and application blanks will be furnished by applying to Captain Louis T. Grant, E.R.C., Secretary, Engineer Training Schools, Camp Humphreys, Va.

A Rocking Electric Brass Furnace

A New Type of Arc Furnace Developed by Metallurgists of the U. S. Bureau of Mines—Comparison with Other Types—Record of Comparative Tests with Coke-fired Furnaces—Power Consumption and Costs

By H. W. GILLETT and A. E. RHOADS

Published by permission of the Director of the Bureau of Mines

IT SEEMS inevitable that the next few years will see electric furnaces largely replacing crucible furnaces in the brass industry; a development comparable to that which the last few years have seen in the steel industry.

With Klingenberg clay not available, and Ceylon graphite requiring ships needed for other purposes, crucibles, despite the good work done by crucible manufacturers, the Bureau of Standards, and others on the problem, are, speaking generally, still of much poorer quality, and many times more costly, than they were under pre-war conditions. The time is ripe for the practical elimination of the crucible from the brass industry.

With the huge tonnage of brass required for war purposes, the use of the small units—averaging 200 lb. per charge—in which crucible melting is done by the brass rolling mills, seems, and is, an anachronism. Besides the avoidance of crucibles and the ability to melt larger charges, electric melting (in a suitable type of furnace) decreases the loss of metal by oxidation and volatilization, prevents the taking up of sulphur from the fuel, gives better and more healthful working conditions, and has many minor advantages such as freedom from handling and storing fuel and ash. Electric furnaces give crucible quality of metal without using crucibles.

Brass Melting Requires Furnaces of Special Characteristics

However not every type of electric furnace can be used for brass melting. If brass did not differ materially from steel in its behavior during melting, electric furnaces would long ago have superseded crucible furnaces. But brass is made up of copper and zinc, and zinc is volatile at brass melting temperatures. For this reason, fuel-fired furnaces of the reverberatory type can be applied to brass only at the expense of a zinc loss so high as to prohibit the procedure. Similarly, the direct-arc type of electric furnace used for steel melting, such as the Heroult, can be used only on bronzes practically free from zinc, because of the high local temperature of the metal under the arc.

Indirect-arc furnaces, such as the Rennerfelt, can be used on brasses containing up to about 20 per cent zinc, but are not suitable for ordinary yellow brass, on account of the formation of a superheated layer on the surface of the bath beneath the arc, and the resulting volatilization of zinc.

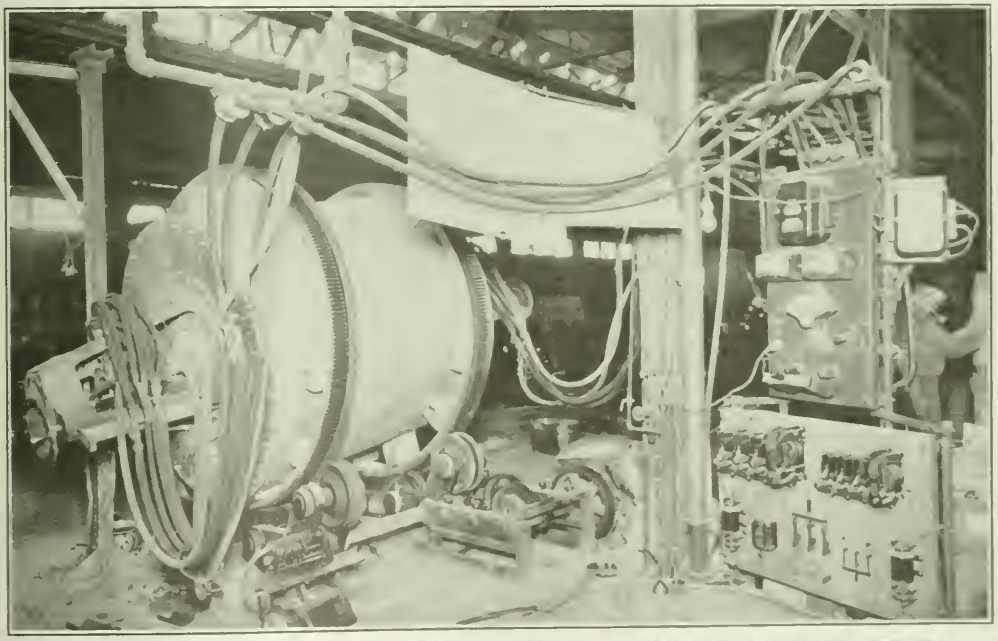

FIG. 1. REVOLVING ELECTRIC BRASS FURNACE AT MICHIGAN SMELTING & REFINING CO., DETROIT

Induction furnaces of the ordinary horizontal-ring type, like the Rochling-Rodenhauser, cannot be used on brass or bronze because the high electrical conductivity of these alloys requires a secondary current so high that the "pinch effect" causes rupture of the secondary ring.

Hence it has been necessary to develop types of furnaces radically different from those in use for steel in order to meet the requirements of brass.

Electric Brass Furnaces in Commercial Use

There are, however, two types of steel furnaces which have been applied to brass (using the term brass loosely to include bronze, red brass, etc.), the Snyder, a single-phase direct-arc furnace, and the Rennerfelt, a two-phase indirect-arc furnace. At the Chicago Bearing Metal Company, Chicago, Ill., two one-ton Snyder and two one-ton Rennerfelt furnaces are melting bronze for railroad bearings, high in lead, but practically free from zinc. The metal losses are not much reduced from previous practice in crucibles and open-flame oil furnaces, but the furnaces are making savings in melting cost as compared with either the crucible or the open-flame furnaces under present conditions.

The Philadelphia Mint is melting nickel and coinage bronze in a 1000-lb. Rennerfelt furnace. The Gerline Brass Foundry Company, Kalamazoo, Michigan, melts Monel metal, red brass and brass containing up to about 20 per cent zinc in an 800-lb. Rennerfelt. The furnace at the Gerline plant is run on a 9-hour basis, while the other furnaces mentioned operate 18 to 24 hours a day.

Two other types of furnace designed especially for brass melting, have also found commercial use, the Baily and the Ajax-Wyatt.

The Baily furnace uses a single-phase granular resistor, the heat from which is reflected down onto the hearth from the roof. It takes charges of about 1000 lb. Baily furnaces are installed at the Lumen Bearing Company, Buffalo, N. Y., Hays Mfg. Co., Erie, Pa., Bridgeport Brass Co., Bridgeport, Conn., and the Baltimore Copper Smelting and Rolling Company, Baltimore. Md. The Baily furnace is applicable to alloys of any zinc content, reduces metal losses, avoids crucibles, and gives good working conditions. The main drawback of this type of furnace is that the source of heat is not close to the melt and the heat must be reflected down from the roof. In order not to overheat the roof and cause its prompt failure, as well as to hold the resistor temperature within the limits that allow reasonable life of the resistor trough, the rate of power input is low compared to the size of the furnace and weight of charge. Hence the radiation losses from walls and roof form a large proportion of the total power. The furnace is at its best on 24-hour operation. When 10-hour operation is necessary, it is found that the furnace must be heated empty during all or part of the night in order to give satisfactory output in the daytime. Because of the high heat storage in the walls, a furnace of this type does not respond promptly to changes in power input, and accurate control of the temperature of the melt is difficult.

The Ajax-Wyatt furnace is a single-phase induction furnace in which the secondary ring is in the form of a loop below the level of the hearth proper, so that the hydraulic head of the metal in the hearth opposes the rupturing effect of the "pinch" force, thus avoiding the troubles that make horizontal-ring induction furnaces inapplicable to brass.

The metal heated in the secondary loop is constantly ejected at one part of each opening from loop to hearth, and colder molten metal drawn in at another part of the opening. These fountains of hot metal issuing from the resistor melt the charge in the hearth. The constant circulation of metal is a most desirable feature and gives a product of remarkably uniform chemical composition.

Because of the compactness of the furnace, the generation of heat within the metal itself, and the stirring action, vertical-ring-induction furnaces are extremely

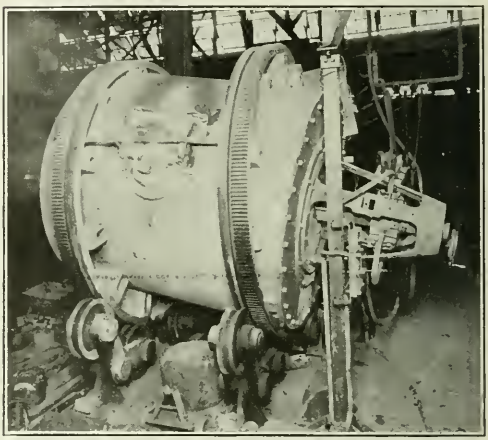

FIG. 2. ANOTHER VIEW OF THE REVOLVING ELECTRIC BRASS FURNACE

efficient as regards power consumption. The power factor, in the sizes so far built, is satisfactory.

The furnace must be started with a charge of previously melted metal, and sufficient metal to fill the loop must be retained when pouring. The metal in the loop must never be allowed to solidify, or the lining will be ruined. These facts make it difficult to change from one alloy to another, and require that the furnace be run 24 hours a day, or else receive enough power at night to keep the metal in the loop fluid. Ramming up and drying the refractory lining of the loop is a job requiring care and experience, as the lining must be perfect or its life will be short. No lining has yet been found that will withstand alloys containing over 3 per cent of lead, and the furnace has been developed mainly for yellow brass.

The furnace is fitted for rolling mill use, where 24-hour operation on yellow brass is the rule, but is distinctly less suitable for 10-hour runs or for foundries making a variety of alloys.

Several of these furnaces are in use at the Ajax Metal Company, Philadelphia, two at the American Brass Company, Waterbury, Conn., and twenty-eight at the Bridgeport Brass Co., Bridgeport, Conn. The furnace saves zinc, avoids crucibles, and shows so low a power consumption on 24-hour operation that it can doubtless be used to advantage in rolling mill practice even under normal prices of fuel and crucibles.

Furnaces Under Experimental Test

Besides the four types mentioned above, each of which has found commercial use where conditions were suitable, there are four other furnaces that have reached a semi-commercial stage, but are still under experimental development.

The Bennett furnace at the Scovill Mfg. Co., Waterbury, Conn., is a three-phase furnace, probably of about 750-lb. capacity, and resembles a direct-arc furnace. However, the voltage between electrodes (which are automatically regulated) and bath is kept so low that there is no true arc and the heat is generated by a sort of contact resistance. This is said to give low metal losses and to show a reasonably low consumption of power.

The furnace has run mainly on yellow brass and is therefore probably applicable to all brasses and bronzes. The results of the work have so far been kept secret and no detailed data are available.

The Foley furnace is a single-phase, vertical-ring induction furnace, similar in general design to the Ajax-Wyatt, although differing from it in many points. One such furnace of about 1000-lb. capacity has been in experimental operation at the Bristol Brass Company, Bristol, Conn., and three 3000-lb. furnaces are under construction. From the few data so far available on this furnace, its metal losses and power consumption will be about the same as in the Ajax-Wyatt; partly because of larger size its power factor is somewhat lower. It has the same disadvantages as regards starting, changing from one alloy to another, and the necessity for 24-hour operation, as that furnace.

The General Electric furnace is a smothered-arc, one or two-phase furnace, normally two of about 1500-lb. capacity, having four depending electrodes, two on each side of a hearth. Between the tips of each pair of electrodes is a carbon block to which arcs are drawn, the arcs being smothered by granular coke. The heat thus generated is reflected down onto the hearth by the roof. The electrodes are automatically regulated.

After being tested at the General Electric Company, Schenectady, N. Y., this furnace has been installed for further test at the Chicago plant of the Crane Company, but is not yet considered ready for general commercial use.

The heat transfer in this type is similar to that in the Baily, and the furnace seems theoretically capable of a performance of about the same order as the Baily with similar advantages and similar drawbacks. As the General Electric furnace takes a higher power input than the Baily, it may be slightly more efficient in power consumption, but the roof is subject to even more severe conditions and will require the use of high grade refractories to give a good life.

The Northrup furnace, being developed by Prof. E. F. Northrup and the Ajax Metal Company, is an induction furnace, heating the charge by means of eddy currents instead of making the charge, or part of it, the secondary of a transformer. Oscillating current of very high frequency is used instead of alternating current, and is obtained by the use of condensers or a special generator. A 60-kw. tapping-type furnace is being tried out. The Northrup furnace has a high power factor, and can take multiphase current. It is being developed in order to produce a furnace suitable for 10-hour operation and for facility in changing from one alloy to another.

Since the heat is generated within the charge itself, the eddy current furnace should be efficient in power consumption. This type is theoretically very promising, but its development has not yet gone far enough to show what, if any, mechanical limitations the type will have.

Many other types of furnaces have been suggested for brass melting, and a number have been tried out more or less thoroughly, but those mentioned above are the most prominent of the types in commercial use or under commercial development. Most of these are either limited in their application, or have some drawbacks, either inherent in the type of furnace, or not yet eliminated by long experience in their design and use, so that no one type or make of furnace is as yet definitely proved the best for any particular set of conditions, and still less will any one furnace meet all the different conditions found in the whole range of the brass and bronze industry.

In particular, none of these types seems quite fitted to that common set of conditions where a furnace may be called upon to melt successive heats of alloys differing widely in composition, to handle both alloys free from zinc and those high in zinc, and to operate cheaply on a 9 or 10-hour day.

Rocking Electric Brass Furnace

In its study of electric brass melting during the past five years, the Bureau of Mines has tried out a rocking-type of furnace, which may perhaps help to fill this gap.

In the ordinary indirect-arc type of furnace, the heat is applied above the melt and as hot metal is lighter than colder metal, there is little circulation in the bath. If the rate of heat input is at all rapid, as is necessary for thermal efficiency, heat conduction from the top of the melt downward does not keep pace with the heat supply. Before the melt as a whole reaches the proper pouring temperature, the surface is much superheated.

On an alloy high in zinc the surface will reach the boiling point of the zinc in that particular alloy while the bottom is scarcely melted. Such heating creates a high pressure of zinc vapor within the furnace so that if it is not tightly closed, zinc is lost continually. If the furnace is sealed tight, the pressure may even blow out the roof or door. In case the furnace holds tight and the pressure is not relieved till the spout is opened for pouring a long hissing stream of zinc vapor then shoots out, burning in the air. This local overheating is the cause of the failure of the indirect-arc furnace to handle alloys high in zinc without large metal losses.

The obvious way to overcome this trouble is to stir the melt so vigorously that the temperature of the melt is practically uniform and the superheating of the surface prevented. The most practical way to stir the melt is by the principle of the cement-mixer, by turning the furnace bodily so as to stir the contents thoroughly while being heated. Constant rotation of a cylindrical furnace placed more or less horizontally, but preferably at a slight angle with the horizontal to produce endwise motion of the melt during rotation, with electrodes entering at the ends of the drum and an arc struck between the electrodes should not only stir the charge thoroughly, avoid surface over-heating and thus pre-

vent zinc losses, but should also give a well-mixed alloy. By washing the walls with metal the heat stored in the walls and roof should be largely taken up in the metal instead of passing out. The power consumption should therefore be low. As the walls are washed with metal their temperature can rise but little above the temperature of the metal, which should give a good life of lining.

Instead of rotating the furnace through a complete revolution which would involve difficulty in keeping the metal out of the joints between the door and the door opening, as this opening should be on the circumference of the drum rather than on the end—and in making brush contacts to the electrodes, it appears simpler to rock the furnace back and forth so that the molten charge just fails to reach the door at either end of its rocking angle.

Results of Laboratory Tests

A small furnace of this type was built and tried out. This was rocked back and forth by hand on tracks. It was cheaply constructed from materials at hand in the laboratory and was not expected to give very good results on power consumption, as the drum was too small to allow the refractory lining to be of desirable thickness.

The laboratory furnace held about 100 lb. of charge, and operated on 50 to 75 volts and 500 to 700 amperes at a power factor of 85 to 90. The usual power input was about 30 kw. Graphite electrodes 2 in. in diameter were used.

A number of different alloys were melted in the rocking furnace. In melting 1092.1 lb. of yellow brass, made up of 45 per cent ingot, 55 per cent copper and zinc, the calculated analysis being 65.6 per cent Cu, 34.4 per cent Zn, 1080.4 lb. of ingot was obtained, analyzing 65.9 per cent copper, 34.1 per cent zinc. The metal loss by weight was 1.06 per cent which includes both volatilization and mechanical loss by spatter in pouring. The average pouring temperature was 1080 deg. C.

On manganese-bronze chips (40 per cent zinc) the furnace gave a net metal loss of 3.0 per cent while the same lot of chips melted in oil-fired crucible furnaces in commercial practice gave 7.2 per cent loss.

Yellow brass chips (25 per cent zinc) gave 1.6 per cent net loss, red brass chips (10 per cent zinc) 1.0 per cent.

A fine concentrate (20-mesh) from brass-furnace ashes, obtained in the manufacture of an alloy of 80 per cent copper and 20 per cent zinc, analyzed 71.0 per cent copper and 14.3 per cent zinc, the balance being ash, etc. After melting in the furnace 99 per cent of the copper and 50 per cent of the zinc in the concentrate were recovered. This material is usually sent to the smelter and refined in a reverberatory furnace, not all of the copper and none of the zinc being recovered.

Yellow brass ingot (25 per cent zinc) was remelted with 0.5 per cent loss. Red brass (10 per cent zinc), made from red gates, scrap copper, yellow chips, lead and tin, was melted with 0.5 per cent loss.

Heavy German silver scrap (18 per cent nickel, 56 per cent copper, 26 per cent zinc) which gave 1.8 per cent loss on commercial melting in coke fires was melted with 1.2 per cent loss.

Sound copper castings were made from metal melted in the furnace.

Red brass of 81½ per cent copper, 8½ per cent zinc, 6 per cent lead, 4 per cent tin, made from red and yellow ingot and scrap copper, was melted in one series of tests with the following results, the furnace being cold at the start.

TABLE 1.

Heat No.	Weight of Charge, Lb.	Time Arc Was On, Minutes	Pouring Temp., °C.	Kw.-Hr. Used	Kw.-Hr. per 100 Lb.
L 34	127 3	57	1,140	40	30¼
L 35	127 75	50	1,180	30½	25
L 36	128. 5	50	1,220	26½	20½
L 37	126. 5	37	1,220	22½	17¾
L 38	129. 5	36	1,220	19	14¾
Total	639 55	Av. 46	Av. 1,200	Total 138¾	Av. 21¾

The total elapsed time for the five heats, including charging and pouring, was 5 hours; 630.9 lb. ingot poured and 7.45 lb. metal from spillings, etc., recovered, giving a gross metal loss of 1.35 per cent and a net loss of 0.2 per cent.

The power consumption, at the rate of 430 kw.-hr. per ton on a five-hour run, starting from the cold, and at the rate of 295 kw.-hr. per ton when the furnace is hot, with the metal heated to 1200 deg. C, is surprisingly low for so small a furnace.

The results above show that the rocking furnace is a type capable of giving low metal loss and low power consumption. When the furnace was not rocked while melting alloys high in zinc, pressure built up within the furnace and zinc losses were high.

Description of Commercial Furnace

The laboratory tests having demonstrated the probable usefulness of the type, a furnace of commercial size was designed.

The Detroit Edison Company had long been interested in electric brass furnaces as a possible outlet for electric power, and offered to co-operate by constructing a rocking furnace for commercial test without expense to the Bureau of Mines except for the salaries and expenses of its representatives while supervising the test.

Sketches of the furnace design were given the Detroit Edison Company, which refined the design, made the working drawings, constructed and erected the furnace. Two views of the furnace are shown in accompanying illustrations.

The drum is 5 feet in diameter by 5 feet long. The lining is 12 in. thick, and consists of Sil-o-cel brick on the outside, special heat-insulating brick in the middle layer and corundite brick (a very refractory firebrick high in Al_2O_3) in the actual hearth lining. The hearth is 3 feet long by 3 feet in diameter, taking charges of 1300 lb. and upwards. The electrodes are 4 in. diameter graphite, threaded for continuous feed, and are adjusted by screw-operated supports of the lathe-slide type. Single-phase, 60-cycle current, stepped down to 120 to 130 volts is used, 30 kva. being available. Electrode adjustment is by hand, and, to stabilize the arc an external reactance is used which brings the power factor of furnace plus reactance, measured at the furnace switchboard, to about 85. The open circuit voltage falls to about 106 to 116 volts under load. The current varies between 1000 and 2000 amperes, 1650 amperes being about the average. The power input can be varied by altering the length of the arc, and runs from 100 to 200 kw. averaging about 165 kw.

The flexible leads and the water hose for electrode cooling are given slack to allow rocking the furnace, as is clearly shown in Fig. 1.

The rocking of the furnace during melting is done automatically by means of a control device which can be set to give a "safe rock" of 80°, the limit of motion being such that the metal just does not run into the spout. After the charge has begun to melt, the "safe rock" is started. It is called the "safe" rock because the angle is such that solid charge will not fall on the electrodes and break them. A complete oscillation on safe rock takes 13½ seconds.

During the safe rock the solid metal is swashed about in the molten part of the charge and is tumbled over, so that fresh surfaces receive direct radiation from the arc. As melting goes on, the rocking angle is increased by turning the handle of the control device from time to time, until, when the metal is all melted, the furnace is on the "full rock" of about 200°. On full rock the metal washes the whole circumference of the hearth save the height of the charging door and a few inches above and below it, so that metal does not splash into the door joint. A complete oscillation takes 53½ seconds.

The reversal of the 5-hp. motor at either end of the rocking angle is done by contactors, operated by solenoids actuated by the contacts on the control device.

When it is desired to depress the spout past the limiting point of the automatic rock, for pouring, the control device is switched out and the solenoids are operated by a reversing switch.

Comparison with Coke-fired Furnaces

The furnace is installed at the plant of the Michigan Smelting and Refining Company, Detroit, Michigan, which makes brass ingot to customers' specifications from chips, scrap and junk of various kinds, by means of strict chemical control. As the firm makes no sand castings, but ingot only, no observations were possible on the comparative quality of metal melted in the electric furnace and in the coke fires. All the metal melted was poured into ingot which went into the regular output of the plant. As far as could be told by analysis and appearance, the electrically melted metal was of at least as good a quality as that from the coke fires. On alloys high in lead there was somewhat less segregation than in the metal melted in crucibles, and on charges high in zinc, the zinc content of the metal from the electric furnace was higher than that from the same charges melted in the coke fires.

As there is generally much oil on the borings and some non-metallic material in the other scrap, the true metallic content of the charge is seldom accurately known. Hence the net metal losses cannot be exactly determined.

The metal losses were therefore compared with those of the coke-fired crucible furnaces operating on the same charge.

From 102 tons of metal melted in strict comparison with the crucible furnaces, the rocking electric furnace produced 3626 lb., or 1.8 per cent more metal from the same charge than did the coke fires. The alloys melted ran from 90 per cent to 66 per cent copper, 1 per cent to 9 per cent tin, 1½ per cent to 26½ per cent lead, 0 to 50 per cent zinc.

The comparative metal losses on a few alloys in the electric and the coke fires are given in Table II

The rocking furnace gave alloys that analyzed very close to the calculated analysis, especially if the difficulty of calculating the analysis of a scrap charge is considered. Characteristic analyses are given in Table III.

There was no difficulty in draining the metal completely from the hearth, and alloys of different composition could be made one after the other without contamination by metal remaining from the previous heat.

The power consumption on 10-hour operation, with no night heating is shown in Table IV, which gives a résumé of 5 days operation.

The power consumption on 24-hour operation is shown in Table V, for a 4-day run.

In the 24-hour tests tabulated in Table V and in a 10-hour run just preceding, in which the 75½ Cu, 7½ Sn, 14½ Pb, 3 Zn alloy was melted, the charge was as follows:

Ingot	25,200 lb
Red borings	11,200 lb 2 [illegible] 224 lb
Medium brass	4,540 lb
Scrap Cu	10,987 lb
Ingot Cu	552 lb
Ingot Pb	3,906 lb
Yellow borings	1,400 lb 3 [illegible] 42 lb
	54,835 266

For the 86 Cu, 6 Sn, 10 [illegible]

Ingot	16,000 lb
Cu	4,704 lb
Pb	[illegible]
	20,800
Total charge	75,635
	266
	75,369

There was obtained:
53,841 lb. [illegible] 75½ Cu
20,149 lb. [illegible] 86 Cu

73,990 lb. total [illegible] 1,379 lb. [illegible] 1.8 per cent
63 lb. scrap 7½ Cu
43 lb. scrap 86 Cu
300 lb. [illegible] 7½ Cu 53 per cent
130 lb. [illegible]

365 lb. [illegible] 429 lb. [illegible]

74,891 lb. [illegible] 44 [illegible]

On the basis of power read on the high-tension side of the transformer, per ton of metal poured, 536 kw.-hr. per ton, on red brass poured at 1180 deg. C. average temperature. For 24-hr. operation the figure is about 260 kw.-hr. per ton for red brass.

The electrode consumption was 16.3 lb. while melting 21660 lb. of metal, or 1.5 lb. per ton, equivalent to about

40 cents at present electrode prices. To this must be added the loss due to accidental breakage. There were nine breakages in melting 72 tons, four of which were due to the charge being so bulky that it fell against the electrodes when rocking started, and five to the electrodes being hit, while bulky material was being charged. The design of the furnace has now been altered so as to allow the electrode tips to be withdrawn into the walls during the charging of bulky material. When an electrode does break, if nipple joints are used, the breakage is usually of the nipple only.

Since the operation was experimental, it is not yet possible to give exact figures on the life of a lining, but as near as can be estimated the relining cost for labor and material should be well under 50 cents per ton with a corundite lining when melting red brass poured at 1150-1200 deg. C. If only yellow brass, poured at 1100 deg. C. is melted, the lining cost will be still lower. If very hot bronze is to be produced, say at 1300 deg. C., the roof and upper portions of the ends should be lined with zirkite brick.

Advantages of Rocking Furnace

Accurate temperature control is very easy in the rocking furnace, since at the end of a heat, after the "full rock," the walls are no hotter than the metal, and there is no heating up of the charge from hotter roof and walls when the power is shut off, as is the case with those types of furnace where the heat is reflected downward from the roof. After cutting off the arc, the temperature falls very slowly, about 2 or 3 deg. C. per minute. By running the arc a minute or so every 10 or 15 minutes, a charge can be held at pouring temperature for an indefinite period.

One man can operate the furnace, with the aid of a helper while charging. Were automatic electrode con-

trol used, which could easily be done, one man could probably attend to two furnaces.

The output per man-hour was greater from the rocking furnace than from the coke fires. The working conditions are much less severe and more healthful with the electric furnace than with the coke fires, and a man of less rugged physique than is required for coke fires can readily operate the rocking furnace.

Various modifications and improvements in design were made during the tests, and others that could not well be made on the first furnace are being incorporated in other furnaces of this type now being built for Detroit firms. The electrodes were at first introduced into the furnace directly through the refractory walls. When making yellow brass from new materials so that addition of much spelter is required, the zinc, vaporized during the addition of the spelter to the molten charge, tended to condense in the clearance between the electrode and the hole through which it entered. This would then freeze, solder the electrode in place and cause breakage. Such trouble was later obviated by the use of graphite sleeves about the electrodes and by the proper arrangement and operation of the electrode coolers. It was also found feasible to charge the zinc with the rest of the charge instead of speltering at the end of the heat.

Comparative Costs and Power Consumption

Comparing the cost of melting on a 10-hour schedule in the rocking electric furnace and in the coke fires of

the plant at which the test was made, the sum of the cost per ton of charge for electric power, interest and depreciation, electrodes, linings, and for heating ladles, is just about one-half of the cost per ton of charge of the single item of crucibles at present prices and at present crucible life. The value of the metal saved by the electric furnace is about twice the cost of the coke used by the coke fires. Hence a huge saving is possible by electric melting under present conditions; and even at pre-war prices for crucibles, coke and metals, the rocking furnace will show a smaller, but still a distinct, saving. On 24-hour operation the balance in favor of electric melting is still more marked.

From data on hand on the power consumption of other types of electric furnaces, it appears that, when operated on the same alloy, heating it to the same temperature, and running the same number of hours per day, the rocking furnace is somewhat more efficient than the direct-arc and un-rocked indirect-arc types, very much more efficient than electric furnaces of types in which heat is reflected onto the charge from the roof, and very little less so than the induction furnaces. These conclusions follow not only from the data at hand, but from the method of application of heat in the various types, those with the source of heat at a distance from the charge being less efficient than those where the heat is developed close to the charge; the induction furnaces in which the heat is developed in the charge itself should be the most efficient. On account of the washing of the walls with the metal, the rocking furnace should theoretically come next to the induction type in thermal efficiency.

Comparative Metal Losses

In magnitude of metal losses, the rocking furnace gives at least as good results as any other type of electric furnace. The only possible loss is from the stream of metal while pouring, as the furnace is sealed tight while running. Volatilization from the stream while pouring is of course about the same in all types of furnaces.

In closeness of control of the temperature of the melt the rocking furnace is superior to any save the induction type. In thorough mixing of the charge, the rocking type is about on the same plane as the induction type, and markedly superior to the other types, where, in large sizes, segregation in the bath may be a serious problem. For example, the following shows the analysis for copper of the first ingot from the first ladle and of the last ingot from the last ladle when melting 1200-lb. charges of 60 per cent Cu, 37 per cent Zn, 3 per cent Pb.

Heat	First Ingot, First Ladle	Last Ingot, Last Ladle
322	59 76% Cu	59 54% Cu
323	59 78% Cu	59 66% Cu

In ability to change from one alloy to another, it is superior to the vertical-ring induction type; and in ability to operate cheaply when used but 10 hours a day, without night heating, it is ahead of the vertical-ring induction type and of the reflected-heat types.

The rocking furnace can handle alloys of any zinc or lead content, being superior on this score to direct-arc, unrocked indirect-arc and induction types. The electrode cost compares favorably with other arc furnaces. With equal conditions of operation, and suitable refractories in each type, the cost of lining will probably be about the same as with most other types. Labor cost should be about the same in all hand-regulated arc furnaces. With automatic regulation, which can be applied if desired, the rocking type should show a labor cost about the same as that of any other type.

Load With Rocking Furnace Not So Steady As With Induction Type

From the electrical point of view, of desirability of a steady load, the rocking furnace does not have so steady a load, and hence, on this score, is not so desirable as the induction furnaces or granular resistor furnaces. It does not require special transformers, as the granular resistor type does. It lacks the electrical advantages of multiphase furnaces. In very large sizes, two arcs could be used in the rocking type, but in sizes up to one ton, single-phase operation is required, and in a plant so located that the power supply must be of limited capacity, a single-phase arc furnace, with its fluctuating loads, may not be satisfactory from the electrical point of view. Such fluctuation is no drawback in Detroit nor would it be in most cities or large manufacturing towns.

From the results on furnaces of 125 and 1300 lb. capacity, it appears that the rocking type can be built in a wide range of sizes without showing a great loss of efficiency in the smaller sizes. This type can doubtless be built in as large sizes as the brass industry could normally use.

In first cost, the rocking type should be no more expensive than other electric furnaces.

While further tests in different plants and under different conditions, which will, at least in part, be made in the near future, are neded to give accurate data on the complete performance of the rocking type of furnace, it would seem from the results so far that it may be of distinct value in the brass industry, especially under present conditions as to crucible prices and quality, fuel supply and prices, and metal prices.

At the conclusion of the tests conducted by the Bureau of Mines, which covered over 300 heats, the experimental furnace was put on regular production by the Michigan Smelting & Refining Co. Four one-ton rocking furnaces are being built for this company and two for the Electro Bronze Co.

Licenses to Make Furnace Granted by Bureau of Mines

The patents taken out by the Bureau of Mines on the rocking furnace have been assigned to the Secretary of the Interior as trustee, and free licenses to operate under them can be obtained by making application through the Director of the Bureau of Mines.

Grateful acknowledgement is made to Cornell University for use of the well-equipped Cornell electric furnace laboratory in the work on the laboratory furnace; to Dr. J. M. Lohr, formerly of the Bureau of Mines, for aid in the work on the laboratory furnace; to the Michigan Smelting and Refining Company for facilities for the test, and to the Detroit Edison Company, and particularly to Mr. E. L. Crosby of the latter firm, for never-failing co-operation.

A more detailed account of the tests of the rocking furnace will soon be published as *Bulletin* 171 of the Bureau of Mines.

The Miles Acid Process for Sewage Disposal

Sewage Disposal Is a Problem in Chemical Engineering to Show How to Use Waste Materials. Tests of a New Chemical Process in Connecticut

SEWAGE disposal is really a municipal problem, and as such there is often the hazard that it may become either Republican or Democratic. When this occurs the best thing for the enquirer to do is to wander away somewhere else for his research, because when politics gets mixed up with it the pollution is likely to become too great even for sewage to endure.

Everybody knows that the situation, as it exists today in regard to municipalities in America is about as bad as it can be, this side of epidemics. In New York Harbor along the Brooklyn shore line there are places where the water is not changed by the tide, where it lacks oxygen and where, in sludge deposits on the bed of the river, a septic condition has arisen. This invites disease and we also know that disease will not refuse an invitation of that sort if there is perseverance in the bidding. Chicago needs more water from the Lake to carry its wastes down the drainage canal, and Uncle Sam seems to be of opinion that Lake Michigan hasn't any more water to spare to hasten Chicago sludge down the Mississippi River. New Haven, Conn., was cautioned by U. S. Government engineers that the harbor was becoming polluted with sewage, and that fishing for oysters must stop. Prof. C. E. A. Winslow of Yale University is now making comparative tests there, to which we shall refer at length later. Boston Harbor is receiving rather more than it can care for without offense to those that go down to the sea in ships and those that live along the shore.

The problem has become one for chemical engineers. The sanitary engineer has looked for and found places where sewage may be put until, so to speak, the places have become all filled up. So it is up to the chemist to find uses for sewage that are at once sanitary and economical, and thus to make it pay back some of the money it costs to get rid of it.

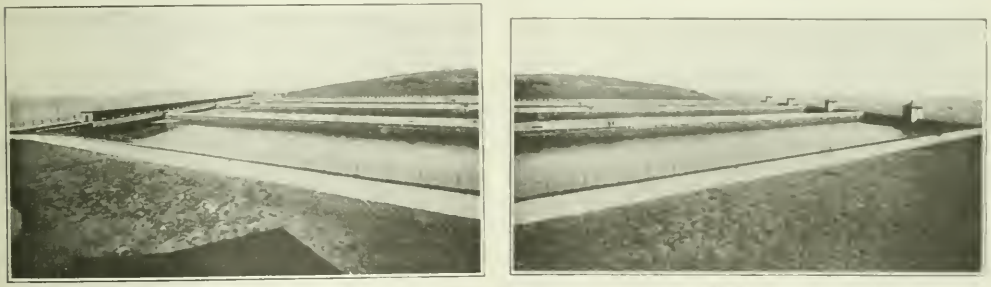
Activation seems to point out a way provided it may be carried far enough. The bacterial action seems to digest most of the polluting material and, under proper control, the effluent may be made crystal clear. The sludge, with fats reduced to 5 per cent or less is proved to be good fertilizer. The cost of installation is, unfortunately, pretty high.

Imhoff tanks get a great deal of the suspended matter from sewage and the effluent may be chlorinated and thus made reasonably safe. The sludge which is saved however, is both offensive and so far, nearly useless. It must be disposed of, and farmers do not seem to care for it.

Outline and Claim of the Miles Process

The acid treatment of sewage discovered and patented by George W. Miles, a Boston chemist, is very promising, and has been the subject of considerable discussion of late. In response to efforts made to establish a municipal sewage recovery plant in Boston a committee was appointed by the Massachusetts legislature to examine the merits of the proposal. In January of this year it made a report adverse to this and other known processes. The committee used bottles for their experiments, and their report is only worthy of interest because it shows the prejudice still to be found in the official mind. One of the special claims for the Miles process is the rapid sedimentation after acid treatment, 4 hours being held to be sufficient for this purpose in practice. The committee in their comparative tests in bottles allowed 18 hours for sedimentation and then drew their conclusions. Experiments of this sort shed darkness rather than light. Their main reason why it was recommended not to establish a recovery plant was because for many years in England, France and elsewhere, efforts to recover and use sewage have been unsuccessful! "Millions for Appropriations but Not One Cent for Research," might well be inscribed upon the City Hall of many an American municipality.

We offer the present record of the Miles process made up chiefly from statements of the inventor and his associates and from data which they have provided. We have also visited a 10,000-gallon test plant at New Haven, Conn., and we shall give a report of its operation at the conclusion. The subject is by far too important to neglect, inasmuch as, according to the claims



VIEWS OF FOUR SEDIMENTATION TANKS OF 12,500,000 GALLONS CAPACITY EACH IN BOSTON HARBOR, PROVIDING AN OPPORTUNITY TO TEST THE MILES ACID PROCESS ON 100,000,000 GALLONS DAILY

of the inventor, an actual solution of the sewage problem is provided, while most of the studies made so far indicate a confirmation rather than a denial of his claims. The claims are in effect as follows: That by treating sewage with SO_2 or with nitre cake in the proper proportion, the soaps are broken up, 98 per cent of the grease is removed and recovered while the resultant sludge is not only inoffensive but an efficient low-grade nitrogen fertilizer; that the effluent is also clear and inoffensive and effectively sterilized; that plants may be established and operated without producing evil odors or unwholesome or unpleasant effects upon the immediate surroundings; that the materials recovered may be sold for enough to pay a fair return on the investment instead of being a tax upon municipalities; and that nothing escapes from the sewers into rivers, harbors or sinks but the sterilized effluent. Indeed, where irrigation is practicable, the effluent, which was found to contain 1000 lb. K_2O, 70 lb. P_2O_5, 120 lb. total organic nitrogen and 1.83 lb. nitrogen as ammonia per million gallons, may be run over limestone and used for irrigation. The excess acid in it was found to be only 30 parts per million.

Municipal sewage, as it emerges from the sewer, is fluid, cloudy and has a slight odor, although the process of fermentation is beginning. On evaporation it yields chiefly ammonia, glycerides, soap and nitrogenous materials. It contains also potash and phosphates, but the potash is mostly lost in the effluent in the Miles process.

Treatment with Sulphur Dioxide

The process provides that at the receiving tanks at the mouth of the sewer, a small portion of the sewage be pumped through an absorption tower with a counter current of SO_2. This SO_2-saturated sewage is run into the main sewer some distance back of its mouth so as to provide for thorough mixing. It flows at low velocity into a settling tank and by a continuous process into a second settling tank from which the effluent flows off. The size of the tanks must be such as to allow four hours for sedimentation in each series of two or more. During the four hours all but two per cent of the solids recoverable by settling are precipitated. The sludge collects at the bottom of the tanks but it is not removed daily. It is desired that it pack down, and to that end it is proposed to operate each series for several days to a week at a time before switching over to a duplicate series of collecting tanks. In tests made, no putrefaction occurs under these conditions. After the liquid is drawn from the settling tanks, the sludge which is pumped out contains 80 to 92 per cent of water, depending upon the method of treatment and the character of sewage.

From experiments made by Professor Robert Spurr Weston of the Massachusetts Institute of Technology on Boston sewage it was concluded that 1963 lb. of SO_2 is required to treat 1,000,000 gallons of sewage. That is roughly, a ton to the million gallons. That would require ½ short ton of sulphur or about one long ton of pyrites to produce the desired effect. Nitre cake may also be used for the purpose of breaking up the soaps, but in that event it is necessary to add a slight excess of SO_2 to stop and prevent fermentation. That is, it was determined by experiment that 3.82 tons of nitre cake was required with 200 lb. SO_2 to treat 1,000,000 gallons of sewage. The result is 1909 lb. of dried sludge, with 430 lb. of fats, according to Professor Weston. The Massachusetts Joint Commission in its adverse reports said that they had made "shorter" experiments which indicated 1427 lb. of dried sludge and 542 lb. fats per million gallons. Of course, neither the sludge nor grease is present in constant proportion but in tests made by Mr. E. S. Dorr of the Sewer Division of the City of Boston from June, 1911, to June, 1914, at frequent intervals there was found in Boston sewage an average of 1914 lb. sludge per million gallons, of which 22.33 per cent was grease by SO_2 precipitation.

The recovered sludge is like greasy, brown or grey mud. It has no odor and even after ten days in hot weather it lacks the offensiveness that it would have immediately acquired without treatment. It has rather a slight mouldy smell if kept too long before degreasing.

Sedimentation of Sludge in Series of Tanks

When the standing liquor has been drawn off and the sewage turned into one of the duplicate series of two or more settling tanks then in operation, the sludge is allowed to drain for a period, and then it is pumped up and, as the season favors, there may be partial air-drying. The final drying must be done under careful temperature regulation to prevent burning. The gases are not offensive and contain no NH_3.

The next process is the solvent extraction of grease from the sludge, which leaves a finely divided, practically grease-free fertilizer material containing 4½ per cent NH_3 and between 1 and 2 per cent P_2O_5. Whether this is economical is a problem in chemical engineering.

This freedom of the sludge from grease is important. It is claimed that sewage farming has generally failed because of the presence of soap and grease which clog the soil and make it "sick." When lime or copperas is used, as is frequently done, the sludge contains insoluble soaps and the value of the fertilizer is not developed. In this process it will be observed that the very first operation is to disinfect the sewage, remove the odor and break up all the soaps before the mouth of the sewer is reached, or as the sewage runs into the first settling tank. The chemical treatment, except the grease extraction, is completed in the very first step.

Commercial Value of Products

In 1913 the Amherst, Mass., Agricultural Experiment Station valued this dried, grease-free fertilizer at $15 to $16 per ton, and announced that over half the nitrogen content was in form to be valuable the first year. The value of nitrogen fertilizer has lately been quoted at $6.50 per unit of ammonia, which would make this which contains 4½ per cent NH_3, $29.25 per ton. It is either a low-grade fertilizer or a fertilizer base, to which tankage, phosphates and other ingredients may be added. Being in a very finely divided condition it should add humus to the soil. Tests for phosphoric acid showed from 1.2 to 1.6 per cent, while K_2O was present only to the extent of 0.03 to 0.14 per cent in the sludge.

The grease produced by extraction consists of glycerides and free fatty acids in the proportion of about half and half. It compares, according to the inventor, with garbage grease. It was worth about 4½ cents per pound at pre-war prices. Since then it has been quoted as high as 15 cents.

One million gallons of sewage at Moon Island, Boston Harbor, produce about 400 lb. of recoverable grease. This sewer, therefore, delivers to the tide, with its 100,000,000 gallons per day, 40,000 lb. of grease. That would indicate, assuming half the grease to be in the form of glycerides, a waste of one ton of glycerine besides 68 tons of fertilizer from this one sewer that now corrupts the harbor with the drainage of about 600,000 inhabitants.

Moisture and Fiber Are Obstacles

The great difficulty lies in the enormous quantity of water that must be evaporated and the fact that 15 to 40 per cent of the sludge is crude fiber. It balls up, and in a steam dryer it will cake and insulate the tubes. In this connection a patent has lately been granted to Mr. Walter H. Sawyer, of Lewiston, Me., who is interested in the company, for a screening device to remove the fiber, wash it with effluent, press down to 50 per cent water, degrease and, possibly, use as cheap paper stock. With the fiber removed the sludge may be reduced from 85 or 90 per cent to 67 per cent water, after which it is to be run through a thermal dryer. To get one ton of dry material from 85 per cent aqueous sludge, 11,000 lb. of water must be evaporated, whereas, when the water is reduced to 67 per cent only 4000 lb. needs to be evaporated; therefore the advantage of multiple effect evaporation, which is feasible down to 67 per cent moisture, may be obtained for 7000 lb. of the water for each ton of dry material. The figures are Mr. Sawyer's.

The effluent shows considerable variation in content. Comparative analyses show 1233 lb. K_2O from the North Metropolitan sewer in Boston Harbor and 888 lb. K_2O in that from Moon Island; 52 lb. P_2O_5 per million gallons also was found in the effluent. The acidity ranged from 1 15 to 1 100 of one per cent sulphurous acid. The bacterial count decreased from 4,000,000 per cc. in sewage to 400 per cc. in the effluent, and these were chiefly mould fungi. The New Haven experiments showed less favorable results in this respect, but it will be noted that the SO_2 supply was occasionally short owing to conditions that will be explained.

Estimated Costs and Profit

With the sewage adequately sterilized and deodorized at the beginning a proper installation should insure against pollution. The usual offensiveness would be done away with and such disposal plants might be put up in decent surroundings within the city limits and without danger of offense or disease contagion. The products recovered are of great economic promise and even in normal times should make the disposal of sewage cease to be the present financial and sanitary burdens that it is upon large municipalities. It provides for the metallurgical utilization of low-grade sulphurous ores, the SO_2 fumes from which may be liquified and shipped to the nearest towns. And it provides also for the use of all the niter cake that is produced. The estimated cost, based on present prices for large-scale plants, is $12,000 per million gallons to be treated daily. Mr. Weston computes the cost of acid treatment to be $7 to $9 per million gallons under pre-war conditions. The value of the grease under pre-war conditions he figures at $16 per million gallons and the fertilizer base as $10.20, or $26.20 for both. Under conditions as of Jan. 9 last, with grease at 15 cents per pound and ammonia in fertilizer at $6.20 per unit per ton, there should be $90.91 return per million gallons treated. That would provide under pre-war conditions $26.20 return per million gallons, less say, $9 for acid treatment, leaving $17.20 to defray cost of drying and degreasing the sludge recovered from a million gallons. Under present conditions with a cost of $20 for acid treatment and $90.91 received for grease and fertilizer, there would remain a margin of over $70 for the same purposes and for profit.

Comparative Test of Four Methods at New Haven

The foregoing figures are gathered chiefly from reports made by Professor Weston and Mr. E. S. Dorr of the Boston Department of Sewers. A late journey to New Haven and a conference with Professor C. E. A. Winslow in charge of the municipal experimental plant and Dr. F. W. Mohlman, his assistant, confirmed the above results in part. The problem at New Haven was not one of sewage recovery but rather the removal of 80 to 90 per cent of the settleable solids, the partial clarification of the effluent and disinfection as required. For this purpose tests of four methods were taken in comparative plants placed at the mouth of the East Street sewer which discharges about 13,500,000 gallons daily into the harbor, a total of more than half the sewage of the city of about 160,000 inhabitants. The tests are still in process and the final reports are not yet made, but thanks to Prof. Winslow and Dr. Mohlman we are permitted to give certain results which have been reached already.

The East Street sewer, 63 in. in diameter, carries the wastes of two great munition works, a part of that of a great hardware manufacturing concern and other important industries, and the experiment emphasizes the fact that sewage is a word with very miscellaneous meanings. The presence of considerable copper in solution from one of the munition works cuts down the bacteria count much below that usually found. A considerable amount of mineral oil is present. One factory pumps up large quantities of sea water for a condenser and this runs the test for chlorine from 14 parts per million at 4 a. m. to 2875 parts at 11 a. m. Condenser water and other industrial wastes dilute the sewage far beyond the municipal average.

The comparative tests are made with (1) activated sludge, (2) Imhoff tank, (3) screening, and (4) Miles-acid. The effluent of all except the Miles process is disinfected by chlorine.

Results in Sedimentation and Bacterial Count

The activated sludge process is too expensive for the purpose and the presence of copper from the munition works and other industrial wastes seem to interfere with the biological conditions demanded by it. The Imhoff tanks give good results in regard to clarification. The accumulation of sludge was less than anticipated. The screening tests were not satisfactory and gave a recovery of less than 10 per cent of the solids.

The Miles tank 4 x 4 x 16 ft. cares for 10,000 gallons daily and has been in operation during the last run from January 26. On March 30 it was still going. There is no sludge on the surface, no gas, and no septic condition. Only 700 lb. SO per 1,000,000 gallons is

used, in view of factory wastes. The effluent is satisfactory and it is exceedingly convenient to handle the deodorized sludge. That which has not been degreased has, after 2½ months, only a slight earthy odor.

With the Imhoff tank the average reduction for November, December and January of suspended solids was 46 per cent. and of settleable solids 83 per cent. The bacteria per cc. at 20 deg. C. were 506,700 in the influent and 640,440 in the effluent while the average gas-formers were respectively 14,920 and 10,530.

With the Miles acid process the average of three tests of 25 days in June, 24 days in July and 44 days in November and December showed a reduction of 59 per cent suspended solids, and 87 per cent settleable solids; while the bacteria per cc. decreased from 558,000 in the raw to 8,000 in the effluent, or 98.5 per cent and gas-formers decreased per cc. from 19,860 to 160 or 99.2 per cent. The wet sludge contained 86.9 per cent moisture and there was 3630 lb. wet and 475 lb. dried sludge per million gallons. The ether extract was 26.5 per cent of dry sludge or 121 lb. per million gallons.

In regard to the bacteria it is noted that the pressure of the SO_2 from the pressure tanks which served for the supply varies with the temperature; that occasionally, despite hourly tests, the acidity would get very low and that frequent adjustments of the valves were necessary. The acidity of many samples tested was below 50 parts per million, and if these tests were discarded the bacterial count would be much lower.

It will be observed that this sewage is remarkably dilute, producing but 475 lb. dried sludge to the million gallons against 1909 lb. found in Boston sewage by Professor Weston. The large proportion of fats in the sewage is confirmed, but the quality of the fats present is seriously affected by the mineral oils contributed from industrial sources. Several laboratories now have samples of the grease under examination. In order to study another type of sewage a small tank with 5000 gallons daily capacity is being tested at the mouth of another sewer, which drains houses and several large laundries, but no manufacturing establishments. This sewage requires far more acid and yields grease of a better quality. The results of these studies will not be known for several months.

The New Haven experiment seems to be bringing the available systems down to Miles-acid and Imhoff tanks. The Imhoff tanks leave the sludge still to be disposed of, which is a difficult and septic mess to handle. The chlorination of the effluent is also expensive. Against this there is the Miles process, with inoffensive sludge and the effluent already sterilized. The sludge will probably have no value unless it is degreased and the question then remains whether there is enough fertilizer and enough grease to pay for the plant. The cost of acidulation varies with the alkalinity of the sewage, while the cost of chlorination of Imhoff effluent is less variable. It is, as we observed before, a problem in chemical engineering and, as Professor Winslow (from whom we gathered the idea) says, "The sanitary engineer should have called the chemical engineer into his counsel long ago, for the problem of today is not how to get rid of things so much as it is how to use them." We agree with him entirely.

There is no conclusion to this article, because the work is not finished, and the acid treatment of sewage is still in the promotion stage. What seems to be brought out is that the SO_2 acidulation of sewage is a considerable contribution to the reduction of offense. The cost of plant and operation and the returns that may be expected are variable because no two sewers are precisely alike in their burdens; but all the problems presented are easy to solve by competent chemical engineers, provided always politics do not enter into the sewage and undo all the good that either chlorine or SO_2 can bring about.

Regulations Concerning Exports to Great Britain, Italy and Belgium

THE War Trade Board announces after consultation with the United States Food Administration, the United States War Industries Board, and the Missions of the respective European allies, that for the purpose of preventing the useless consumption of materials and labor in making articles for export which for the present may not be exported, and for the purpose of saving tonnage by prohibiting the exportation of articles which have not been recommended by the Government of the country of destination as being necessary for their essential requirements, the War Trade Board has adopted the following additional rules and regulations with respect to the issuance of licenses to export any commoodity to the United Kingdom, France, Italy and Belgium (excluding their respective colonies, possessions and protectorates).

On and after May 15, 1918, applicants, before filing applications for licenses to export any commodity to the above named countries, must obtain thereon the written approval of the mission in the United States of the country to which the exportation is to be made. To secure this approval, applicants should forward their applications, duly executed, in triplicate, with proper supplemental sheets attached thereto, including Supplemental Sheet X-11 or X-12, as may be required, to:

The British War Mission, Munsey Building, Washington, D. C. For shipments to the United Kingdom.

The French High Commission, 1954 Columbia Road, N. W., Washington, D. C. For shipments to France.

The Italian High Commission, 1712 New Hampshire Ave., N. W., Washington, D. C. For shipments to Italy.

The Belgian Commission, Room 202, Council National Defense Bldg., Washington, D. C. For shipments to Belgium.

One copy of approved applications will be forwarded by the Missions directly to the War Trade Board, Bureau of Exports, Washington, D. C.; one copy retained; and the other copy returned to the applicant for his convenience in keeping a record.

Applicants will be required to agree with the War Trade Board not to purchase nor acquire for export nor take any steps in the process of producing manufacturing or fitting for export the articles specified in the application until an export license has been duly granted.

On the Molecular Physics of Ore Flotation[1]

By WILL H. COGHILL[2] and C. O. ANDERSON

Introductory

IT IS COMMON practice to inquire into the efficiency of a process as soon as it has been made commercially successful. So it has been with the flotation process. Hoover[4] makes an erroneous statement about the force required to penetrate a liquid surface, and with it as a basis calculates and tabulates the actual and theoretical capacities of several types of flotation machines. Other writers have made similar efforts by using principles incorrectly. The most striking case is that of Van Arsdale.[5] He begins with the premise that "the maximum weight that can be supported on the surface of water is equal to the surface tension of the area supporting the weight." Beginning thus with a false premise, naturally he ends with false conclusions. It is scarcely hypercritical to say that for these fallacies to go unchallenged after receiving favorable editorial comments and being incorporated in a book, portends a tardy science of flotation.

In this discussion the underlying principles involved in calculating the flotability of solids and constructing profiles arising from surface tensions will be pointed out and the calculation of "theoretical capacities" left to the more ambitious.

Maximum Depression Against a Vertical Plate

Imagine a plate of unit horizontal length placed vertically with its lower edge below the surface of water with its faces so prepared that on one side $\theta = 90°$ and on the other, $\theta = 180°$. (θ is the angle of contact). It will appear in cross section at right angles to its length as shown in Fig. 1. Let h be the depth of the dimple in centimeters. It is obvious that the sum of the horizontal forces must be zero, otherwise there would be motion, and work would be done without the expenditure of energy, which is contrary to the laws of nature.[6]

Since, on one side, the surface of the dimple meets the plate at 180°, the horizontal component of the pull due to surface tension is zero. On the other side, it is 0.0715 gram (the assumed tensile strength of the film). Opposite and equal to this force is that of the head of the water from a to b, which is

$$h \times \frac{h}{2} = \frac{h^2}{2}; \quad \frac{h^2}{2} = 0.0715$$

$h_1 = 0.143$.

$h = 0.378$ centimeter, the maximum depth possible in pure water where the face is vertical.

Maximum Rise Against a Vertical Plate

The profile of the liquid surface wetting the glass, Fig. 2, is the inverted profile of the one where $\theta = 180°$ in Fig. 1, because hydrostatic pressure is the only variable, and it varies directly with depth—from the top of the meniscus in Fig. 2 to the bottom of the dimple in Fig. 1. The maximum rise is therefore 0.378 centimeter. The radius of curvature at any point is determined by the formula

$$P = \frac{T}{R}$$

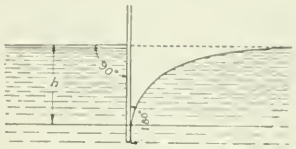


Fig. 1
Vertical plate with faces prepared so that θ is 90° and 180°

Note that in Fig. 1, where h was found to be 0.378 centimeter, the solid face was vertical. The maximum depth is obtained when the non-wetted face is horizontal. Let this depth be H.

Profile of a Drop of Water

If the liquid is resting on a solid which it meets at an angle of 180°, the drop will appear as shown in Fig. 3. The total hydrostatic pressure against an imaginary vertical plane of unit horizontal length against the right end is $\frac{H^2}{2}$. The opposite and equal force is 2 T, where T is the tensile strength measured in gram-weight per unit-length of film.

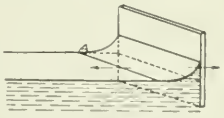

Fig. 2
Capillary rise against a vertical plate

$$\therefore \frac{H^2}{2} = 2T, \; H^2 = 4T = 0.286$$

$$H = 0.535 \text{ centimeter.}$$

To draw this, take a horizontal line to represent the upper plane surface. Having the value of H, take another line to represent the surface of the solid on which it rests. Let the surface of the water meet the solid surface at A. The radius of curvature R of the surface of the water where it leaves this solid is found by substituting the values for T and H in the formula for radius of curvature as given above.

[5]G. D. Van Arsdale: "How Flotation Works," Eng. & Min. Jour., 101, 851 (1916).

[6]The equilibrium of this system and the one in Fig. 2 was discussed by Le Conte and Riley in the Philosophical Magazine in 1883. Le Conte fell into a dispute with Young who "insisted that according to Laplace's theory the horizontal molecular pressures on the opposite faces being unequal, the composite plate should be drawn in the direction of the center of concavity of the meniscus on the glass face (Fig. 2), and thus cause the entire system to take on a motion of translation.

He, therefore, "made the following arrangements with the view of experimentally testing the question. A plate of well cleaned glass and a plate of polished steel were cemented together so as to constitute a composite plate of these substances. This was floated in a vertical position by securing masses of cork to the two faces, and attaching a leaden sinker of the proper weight to the lower extremity of the plate. If such a composite plate is plunged vertically into alcohol contained in a large vessel, a concave meniscus will be formed by the ascending liquid on the glass face, while on the steel face no meniscus will be formed, and the adjacent surface of the alcohol will be horizontal. There was no evidence of unbalanced forces on the floating face."

Riley investigated these principles and in liquid condition represented by Fig. 1 and found that in "every case the identity shewn that the magnitude of these two forces is just the same as if the surfaces came up perfectly level to the plate without any elevation or depression."

$$P = \frac{T}{R} = H$$

$$0.535 = \frac{0.0715}{R}$$

$$R = 0.134 \text{ centimeter.}$$

From "A" measure a distance R vertically upward, and with the point so chosen, describe a small circular arc radius R, to represent the lowest arc of the profile. The remaining arcs of the profile are drawn as indicated by the figure.

It is not absolutely correct mathematically to apply the formula

$$P = \frac{T}{R}$$

in this case. It is correct only when a surface element is obtained by bending a flat surface about a straight

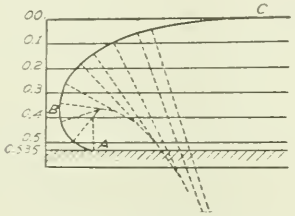

Fig. 3
The arc method of constructing the profile of drops of water

line as an axis, *i. e.*, only one plane of bending, giving a cylinder. With the flattened drop there are really two planes of bending at right angles to each other, and when the radii are R_1 and R_2, the correct formula is

$$P = T\left(\frac{1}{R_1} + \frac{1}{R_2}\right)$$

Generally, however, R_2 is so large that $\frac{1}{R_2}$ may be neglected. When $R_1 = R_2$, we have, of course, the spherical drop.

The Proverbial Steel Needle

The following demonstration of equilibrium of the floating needle is taken from Edser:[2]

Let Fig. 4 represent the transverse section of a needle of radius r, floating on water. Let the surface of the water leave the needle tangentially at B, where the radius CB of the needle makes an angle A with the vertical. Let the point D be at a distance, h, below the flat surface of the water.

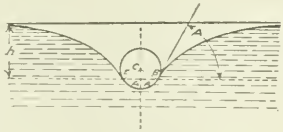

Fig. 4
Transverse section of wire floating on water when θ is 180°

The following are the upwardly directed forces acting on unit length:

The force due to the surface tension of the water is equal to

$$2\ T \sin A \qquad (a)$$

If the portion of the needle below the horizontal plane EB were removed, the hydrostatic pressure of the water would exert an upward force equal to

$$2\ r \sin A\ h \qquad (b)$$

The additional upward force due to the segmental portion of the needle below EB is equal to the weight of the water displaced by this portion of the needle; that is,

$$r^2\left(\pi \cdot \frac{A}{180} - \sin A \cos A\right) \qquad (c)$$

It is assumed that the length of the wire in comparison with the diameter is so great that the surface-tension pull upon the ends may be neglected.

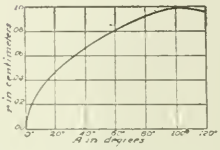

Fig. 5
Graph exhibiting relation of r and A for steel wire on water where θ is 180°

The downward force is

$$7.7 \cdot \pi\ r^2 \qquad (d)$$

We now wish to eliminate h in Equation b. Inspection shows that for horizontal forces in FB to be in equilibrium,

$$\frac{h^2}{2} = T - T \cos A$$

$$h = 2\sqrt{T}\sqrt{\frac{1 - \cos A}{2}}$$

$$= 2\sqrt{T} \sin \frac{A}{2} \qquad (e)$$

Substituting this value for h in equation b and equating the upward and downward forces, we obtain the equation

$$2T \sin A + 4r \sin A \sin \frac{A}{2} \cdot \sqrt{T} - r^2\left(\pi \cdot \frac{A}{180} - \sin A \cos A\right) = \pi r^2 7.7$$

Setting sin A cos A equal to 0.5 sin 2A $\qquad (f)$

and transforming,

$$r^2\left(24.2 - 0.5 \sin 2A - \pi \cdot \frac{A}{180}\right) - 1.07r \sin A \sin \frac{A}{2} = 0.143 \sin A \qquad (g)$$

Fig. 5 shows the values of r for values of A lying between 0° and 120°. It will be noted that the maximum value of r corresponds to A = 100°, and is equal to 0.0995 centimeter, or roughly 1 mm. Thus the diameter of the largest needle that can float on water is equal to two millimeters approximately. The position of the needle relative to the surface is shown in Fig. 6. The curve in Fig. 5 shows that the needle is in unstable equilibrium when A is greater than 100°.

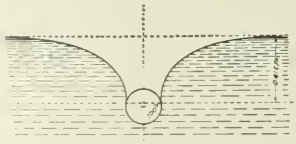

Fig. 6
Steel wire floating on water where θ is 180° and r is a maximum

Liquid Profiles.

A method of constructing liquid profiles is shown in Fig. 3. Its inaccuracy becomes apparent when one attempts to apply it; there is a cumulative error which necessitates "fudging" the curve to make it become tangent at "C." An exact method is desirable.

[2] Edwin Edser: "General Physics for Students," p. 340 (1911).

A search of the scientific literature reveals the fact that some of the scientists have been unable to deal with this curve in a scientific manner, using instead "cut and try" methods. A striking example of this is found in the paper of Richards and Coombs,[8] where they made elaborate experiments to "discover" the "diameter necessary in order to attain the flat surface with which the capillary rise is to be compared" while measuring surface tension by the capillary rise method. After investigating the literature and making many tests, they decided that "in the 38 mm. tube, a portion in the middle, apparently about 5 mm. in length, appeared to be flat, coinciding exactly with the horizontal spider-line of the telescope." From this it appears that in a a large glass receptacle where θ is zero, or nearly so, the meniscus would coincide with the plane surface of the liquid at a distance 16.5 millimeters $\left(\frac{38 - 5}{2}\right)$ from the wall. Since the upper portion of the profile (that above B) in Fig. 3 is like the inverted profile of the meniscus referred to, it would be expected therefore that the horizontal distance from B to C would be 1.65 centimeters. The error in the conclusions of Richards and Coombs is indicated below.

Construction of Profile Based on a Co-ordinate System

A comparison of the theoretical and observed positions of floating cylinders where the specific gravity, angle of contact and surface tension are known would add to the significance of these factors when applied to the study of floating minerals. To do this a correct liquid profile must be constructed by means of co-ordinates. Gray's[9] work aids in this regard. Under the subject of capillarity he gives the equation of this curve but treats it so academically that one finds it difficult to make the technical application. His equation is

$$x = -(4a^2 - y^2)^{\frac{1}{2}} + a \log \frac{2a - (4a^2 - y^2)^{\frac{1}{2}}}{y} + C$$

It is interesting to note at this point that Lord Kelvin

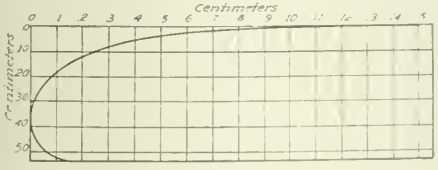

Fig. 7
Profile of standing water with one plane of bending
T = 0.0715 gram

and Tait[10] have likewise applied this equation to the curve of a bent wire. Hall[11] has also used it. If we set $2a = 0.535$ (the value of H), $C = 0.1427$ and change the Napierian logarithm to the common system by multiplying by 2.3, it takes the form

$$x = -(0.2862 - y^2)^{\frac{1}{2}} + 0.6152 \log \frac{0.535 - (0.2862 - y^2)^{\frac{1}{2}}}{y} - 0.1427$$

Table I gives the x, y ordinates.

The remarkable coincidence of this curve (Fig. 7), with the portion of Fig. 3 in which the arc method of construction has the minimum error, and the deviation from it where the error is obviously maximum, dispels all doubt toward the application of the formula to the profile of a standing liquid with one plane of bending."

TABLE I. CO-ORDINATES FOR LIQUID PROFILE WHERE THERE IS ONLY ONE PLANE OF BENDING.

T = 0.0715 g. sp. gr. = 1

x	y	x	y
0.143	0.535	0.1828	0.13
0.0809	0.52	0.2032	0.12
0.0645	0.51	0.2240	0.11
0.0517	0.50	0.2479	0.10
0.0332	0.48	0.2749	0.09
0.0149	0.45	0.3052	0.08
0.0050	0.42	0.3409	0.07
0.0011	0.40	0.3799	0.06
0.0000	0.378	0.4278	0.05
0.0018	0.35	0.4768	0.04
0.0085	0.32	0.6714	0.02
0.0154	0.30	0.8663	0.01
0.0244	0.28	0.9331	0.0075
0.0421	0.25	1.0015	0.0050
0.0580	0.23	1.2266	0.0025
0.0746	0.21	1.3630	0.0015
0.0843	0.20	1.4710	0.0010
0.1199	0.17	1.5480	0.00075
0.1496	0.15	2.0866	0.00010
0.1671	0.14		

Reference to the last two values of y and x in Table I shows that the 1.65 centimeters, taken by Richards and Coombs as the distance from the solid at which the meniscus coincides with a plane surface, allows an error of less than 0.00075 centimeter and more than 0.00010 centimeter. This appears in Fig. 7 and Table I.

Having this curve, we can now consider the angle of contact.

The Practical Formula for Steel Wires Floating on Water.

In the formula developed for the floating "needle," θ was taken as 180°. Since this value is likely never found in practice, it must be regarded as ideal. By a simple substitution a variable which will make it applicable for all values of θ is introduced, after which theoretical and observed values may be compared.

The corrections are simple, though at first somewhat confusing.

Since, in practice, the angle of contact is always less than 180°, an angle D is introduced to represent this difference. Equation *a* then becomes,

$$2T \sin (A - D) \qquad (a')$$

Equation *e* becomes

$$2L = T \sin \frac{A - D}{2}$$

and when this value is substituted in (*b*) we have

$$4rL = T \sin A \sin \left(\frac{A - D}{2}\right) \qquad (b')$$

The expressions (*c*) and (*d*) are unchanged.

Equation *g*, which applies to steel wires, then becomes

$$r\left(21.2 - 0.5 \sin 2A \frac{A}{180}\right) = 1.07 \sin A \sin \left(\frac{A - D}{2}\right) - 0.143 \sin (A - D) \qquad (g')$$

Table II gives the values of A and D for stated values of θ.

Fig. 8 shows the curves conforming to the co-ordinates given in Table II.

The Relation of Angle of Contact to Flotability.

We now have sufficient data to show the relation of the angle of contact to the flotability of cylinders. The

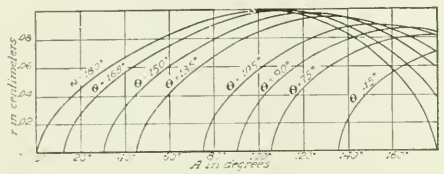

Fig. 8

Curves showing the theoretical values of A for steel wires for stated values of r and θ

subject begins to take the aspect of a science when we see from this figure that if r is sufficiently small a solid is flotable though θ may be as small, for example, as 45° or less. Previously, the fact that pieces of glass floated on water could be explained only by the "air cushion" theory. Such an hypothesis must now give way to facts. Consider, for example, a steel wire with a radius of 0.06 centimeter. Reference to Fig. 8 shows that when $\theta = 180°$, $A = 33°$; $\theta = 168°$, $A = 44°$; $\theta = 150°$, $A = 60°$; $\theta = 135°$, $A = 74°$; $\theta = 105°$, $A = 102°$; $\theta = 90°$, $A = 117°$; $\theta = 75°$, $A = 133°$; $\theta = 45°$, $A = 165°$. The very slight drop in the consecutive crests of the curves from left to right, while θ decreases from 180° to

Fig. 9

Showing how a steel wire of given diameter ($r = 0.06$ cm) rides on pure water while θ decreases from left to right

45°, is striking. But this must not be taken to indicate relative flotability in practice. For, though it is true that increasing "A" brings the object near the point of unstable equilibrium (the descending portion of the curve), yet another factor of no less importance appears in practice. It is the position of the walls of water with reference to the object, and to each other. Note in Fig. 9, *a*, how the object rides safely on a disturbed surface, while in Fig. 9, *h*, there is continual danger of the walls overlapping and causing submergence. When they overlap and coalesce, the surface tension film, of course, vanishes. A little lycopodium powder or talc on the surface assists in maintaining the interface by preventing coalescence. Is it not probable that the insoluble oil used in flotation acts in the same manner, preventing the coalescence of the walls of the bubble whenever it is in danger of being separated from the mineral?

These theoretical considerations would have greater significance if supported by physical measurements and observations. Such tests have been made with the cathetometer, and the agreement of observed and calculated values justifies the theory. Let us first consider the principles involved in constructing Fig. 9, after which we shall consider the physical measurements.

Take, for example, Fig. 9, *b*. The radius of the steel wire is 0.06 centimeter and θ is 168°. The angle D is therefore 12°. Look along the line (Fig. 8), corresponding to $r = 0.06$ cm. and find where it intersects the curve marked "$\theta = 168$." Here the corresponding angle A is 44°. Now use the modified form of Equation *e*, which is,

$$h = 2r \sin \frac{A - D}{2}$$

This gives the value of h, which is then applied to Fig. 9. At the point on the curve so determined strike off the radius of the object so that "A" has the value desired, and draw the circle.

Of course, θ must be determined by test. The classic methods for this determination were considered, but discarded in favor of an indirect method in which the cathetometer was used. Here the capillary rise or depression against a vertical plane surface was determined, and θ was found by means of the above equation by solving for D after setting A equal to 90°. When there is capillary rise, θ equals D, and for capillary depression θ equals 180° minus D. Pure water gives an angle of contact of 168° against a surface prepared by dipping a solid into molten paraffin and sprinkling lycopodium powder on it before the paraffin congeals. Against solid paraffin the angle is 105°.

Table III shows that the observed and theoretical position of steel wires floating on pure water coincide with a satisfactory degree of accuracy. The cathetometer was used to measure the vertical distance from the plane surface of the water to the bottom of the floating wire. No correction was made for the thickness of the paraffin shell, which was found to be very thin—only 0.01 centimeter. Fig. 10 shows the theoretical position of these wires on the liquid profile. The liquid

meets the heavy and dotted circles at 168° and 105°, respectively.

The Flotation of Aluminium Wires

From the standpoint of the metallurgist, we are still dealing with an ideal case because minerals cannot be obtained in the form of right circular cylinders; again,

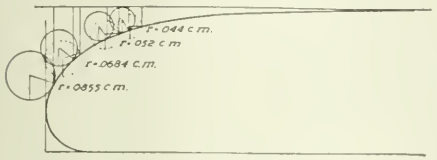

Fig. 10
Theoretical positions of steel wires floating on water where T is 0.0175 and θ is 105° and 168°, respectively.

steel wires have a greater specific gravity than many of the metallic sulphides. In order to transform ideal conditions into the practical, let us make a further study of the effect of specific gravity, reserving the question of shape of the floating object for a later discussion.

Having made a study of the conduct of wires heavier than the average of the metallic sulphides, it seems that if we would make a similar study of those lighter than the minerals and find an agreement also between theoretical and observed values, we could use mathematical processes for predicting the conduct of any mineral. The following results deal, therefore, with aluminium wires:

When aluminium wires (specific gravity 2.7) are used, the equation corresponding to Equation g' is

$$r^2\left(8.4823 \cdot 0.5 \sin 2A - \frac{A}{180}\right) = 1.07r \sin A \sin\left(\frac{A - D}{2}\right)$$

$$= 0.143 \sin (A - D)$$

The values of A and r for stated values of θ are shown in Table IV.

TABLE IV. VALUES OF r AND A ALUMINIUM WIRES

$\theta = 168°$ D = 12°		$\theta = 105°$ D = 75		$\theta = 90°$ D = 60	
A	r	A	r	A	r
12	0.0000				
20	0.0499				
30	0.0775				
40	0.1004				
50	0.1216				
60	0.1422				
70	0.1626				
		75	0.0000		
80	0.1812	80	0.0446		
90	0.1986	90	0.0833	90	0.0000
100	0.2129	100	0.1145	100	0.0686
110	0.2210	110	0.1413	110	0.1033
120	0.2262	120	0.1630	120	0.1312
130	0.2217	130	0.1795	130	0.1531
140	0.2083	140	0.1832	140	0.1686
150	0.1860	150	0.1931	150	0.1771
160	0.1564	160	0.1870	160	0.1769
170	0.1182	170	0.1761	170	0.1733
180	0.0744	180	0.1602	180	0.1631

These points are plotted in Fig. 11. The scale is the same as that of Fig. 8. Note how they have the same general form as those for steel, but run up much higher on account of the lesser density of the aluminium. The remarkable coincidence of the theoretical depth with the observed depth of the bottom of the wire below the plane surface of the liquid again substantiates the theory. See Table V.

TABLE V.—SHOWING THE OBSERVED AND THEORETICAL DEPTH OF ALUMINIUM WIRES FLOATING ON PURE WATER

Radii of Wire in Centimeters	$\theta = 168°$ Depth in Centimeters		$\theta = 105°$ Depth in Centimeters

0.065	0.067	0.065	0.102	0.100
0.095	0.136	0.140	0.190	0.195
0.192	0.494	0.500		
0.215	0.680	0.642		

Fig. 12 shows the theoretical position of these aluminium wires on the liquid profile. The liquid meets the

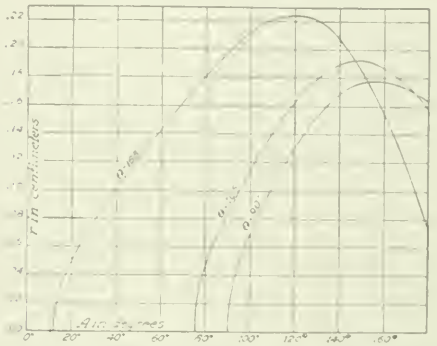

Fig. 11
Curves showing the theoretical values of A for aluminium wires for stated values of r and θ.

heavy and dotted circles at 168° and 105°, respectively, as in Fig. 10, where the steel wires were shown.

Anderson[1] says: "A needle, especially if slightly oily, will float if carefully placed upon water. We may note in passing that the weight of the water displaced by the sagging of the surface film is equal to the weight of the needle (Archimedes' Principle)." This statement will be discussed in another paper.

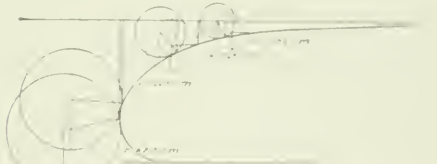

Fig. 12
Theoretical [illegible] floating [illegible]

The Flotation of Galena

To compare the conduct of the mineral grains fed to a H. F. Wood flotation machine to a group of skaters where some glide over the ice and others break through, is an analogy that is fruitless. Ice breaks when the molecules are removed beyond the limit of influence, but at the instant when galena [illegible] the molecules in the surface of the liquid are under the same stress as those on an undisturbed surface. To speak of the membrane rupturing or breaking at the instant the galena becomes submerged, is [illegible] far from accuracy as is the

[illegible]

North from the South. We must have the facts or continue the guessing process in flotation, which, it must be admitted, has, in some cases at least, produced such favorable results that a "small piece of cheese has been left for the cats after the monkey got his portion."

What is the position of floating galena relative to the liquid profile? The angle of contact of pure water against cleavage face is approximately 45°. Is a mineral flotable when the water turns up at this angle to meet a vertical face? Figs. 8 and 9 show that wires are, and it seems consistent to assume that the same conclusion applies to minerals. Conjecture offers only one explanation—diagrammed in Fig. 13. Cathetometer observations show that this is a reality. The liquid profile meets the upper horizontal face (at 45°), the proof of which is shown in Table VI.

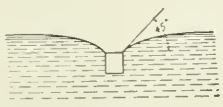

Fig. 13
Diagram showing how galena floats on water when θ is 45°

TABLE VI CATHETOMETER OBSERVATIONS ON FLOATING GALENA

Approximate Mesh	Vertical Dimensions in Centimeters: Of Galena	Bottom of Galena to Intersection of Liquid Profile With Galena
36-mesh	0 040	0 055
33-mesh	0 045	0 055
13-mesh	0 130	0 150
12-mesh	0 140	0 150

In each observation the readings showed that the mineral was wholly below the bottom of the dimple.

Summary

The maximum rise and depression of a given liquid against vertical plates are determined and shown to be the same for angles of contact of 0° and 180°, respectively. The horizontal pull of the film is independent of the angle of contact.

A graphical method of constructing a liquid profile with one plane of bending is reviewed.

A review is given of the mathematical discussion of the floating needle when the angle of contact is ideal.

A liquid profile with one plane of bending is constructed on a co-ordinate system, and compared with the arc and "cut and try" methods.

A practical formula for steel wires floating on water is developed from the ideal and theoretical and observed values are compared.

A formula is developed for calculating angle of contact from the cathetometer measurements of rise or depression of a liquid against a vertical plate. The relation of angle of contact to flotability is indicated by curves and checked by observations.

The flotation of aluminium wires is treated scientifically and practically.

The manner in which "floating" galena is suspended at the surface of water is shown.

Brazil Subsidizes Caustic Soda.—Owing to the impossibility of obtaining supplies, the Brazilian Government has just published a decree offering financial assistance to establish caustic-soda factories, loaning up to 75 per cent of cost of construction, the amounts not to exceed $500,000 for each of the first three factories with minimum production of 500 tons per year.

Research Fellowships in Metallurgy School of Mines, University of Idaho

In co-operation with the United States Bureau of Mines, the University of Idaho, through the generosity of the mine owners of the state, offers in the School of Mines a number of fellowships in metallurgy. These fellowships are open to college graduates who have had good training in chemistry and metallurgy, and who are qualified to undertake research work. The income of each fellowship is $720 a year of twelve months beginning July 1st, 1918.

Fellows will register as students in the University of Idaho and become candidates for the degree of Master of Science in Mining or Metallurgy (unless this or an equivalent degree has been earned.) Their class work will be directed by the heads of the departments of instruction, but the greater portion of their time will be spent in research work under the direction of the Bureau of Mines staff resident at the University. The purpose of this work is to undertake the solution of definite problems confronting the mining and metallurgical industries of the state of Idaho. For 1918-19 the following subjects are to be investigated:

(1) Differential flotation—with especial reference to the zinc-lead ores of the Coeur d'Alene.

(2) Availability of western wood-oils for flotation concentration.

(3) Treatment of the complex gold-silver ores of southern Idaho.

Under the ruling of the War Department candidates 21 years of age or over who are accepted for the fellowship, will be allowed to enlist in the Engineers Reserve Corps detailed to continued their studies, and placed in a deferred classification for the period of their enrollment as graduate students.

Applications, with certified copy of collegiate record, and names and address of three references will be received up to June 1st, 1918. The applications should be addressed to The Dean, School of Mines, Moscow, Idaho.

Kaiser Wilhelm Trust for Promotion of the Science of War

The Kaiser has approved the foundation of a Trust with the name given above. The aim of the Trust is to further the development of scientific and technical aids to warfare, by uniting the scientific and the military forces of the country for work together. The scientific work is to be carried on by the following technical committees (or commissions):

(1) Committee for the chemical raw materials, for the production of munitions-manufacturing materials.

(2) Committee for chemical war materials (powder, explosives, gas, and the like).

(3) Committee for physics, including balistics, telephony, telegraphy, determination of targets and distances, measurements, and the like.

(4) Committee for engineering and communication.

(5) Committee for aeronautics.

(6) Committee for obtaining and preparation of metals.

The Economic Position of Oil Shales

Economic Distribution, Methods of Production and Comparative Yields

BY JAC C. MORRELL AND GUSTAV EGLOFF

THE increasing need of petroleum oil is steadily outdistancing the visible supply to such an extent that the oil shales of the West are already being considered not only to make up a developing shortage, but as the future oil reserve. Various statistics show that since 1913 the consumption of petroleum crude oil has grown faster than production at the wells in the United States. The Government has classified 3,692,036 acres as oil-shale land in the West. During the last year two oil-shale reserves were created for the use of the navy, one of 45,440 acres in Colorado, and one of 86,584 acres in Utah.

Statistical Situation

In Senate document 310 it is indicated that the maximum amount of oil in the known oilfields would yield 7,629,000,000 barrels. From 1859 to Jan. 1, 1918, the total number of barrels of crude petroleum oil produced in the United States was 4,200,000,000. From a production of 2000 barrels in 1859 the number increased to 286,000,000 in 1917. M. L. Requa has stated that by assuming the annual increase as 5 per cent of the previous year's production, there would be required in 1925 409,000,000 barrels of crude oil. In 1917 the production of crude oil was 286,000,000 barrels, and, according to the Geological Survey, there is only 7,629,000,000 barrels of extractable petroleum oil in the known fields of the United States. Thus there is only a known oil supply available for twenty-three years. This calculation is on the assumption that there is no yearly increased demand for petroleum products. But on the basis of past yearly increase in petroleum consumption the estimated available supply will last probably fifteen years.

KEY MAP OF NORTHWESTERN [illegible] AND ADJACENT AREAS

Assuming that new oilfield deposits and known production may be tripled, our oil supply will last a scant fifty years. It is well known that a number of our oil areas are decreasing yearly in production, and although the total barrels of crude oil production increases yearly, the amount is not great enough to supply the demand for refined products. Hence, the necessity of taking crude oil from storage. On Jan. 1, 1916, 198,000,000 barrels of crude oil and on Jan. 1, 1918, approximately 155,000,000 barrels were in storage, which shows a depreciation of 43,000,000 barrels, leaving less than a six months' supply of crude oil above ground for refining. In 1917 there were 359 refineries in operation, with a yearly capacity of 450,000,000 barrels of crude oil.[1] At the present time there are 118 new refineries building, with a yearly capacity of 40,000,000 barrels. In the year 1918 there will be operating 477 refineries, with a yearly capacity of 490,000,000 barrels.

The United States production of petroleum crude in 1918 will be 300,000,000 barrels. The addition of 50,000,000 barrels from Mexico will give a total of 350,000,000 barrels, but this quantity will not keep the refineries at capacity operation, unless several Cushing, Towanda and Eldorado pools are brought in or the difference be piped from Mexico's prolific field to meet the increasing demand for refined petroleum products. Although the petroleum crude oil of the United States may be exhausted in fifty years, one must not forget the vast deposits in Mexico. For the year 1916 Mexico shipped 40,000,000 and in 1917 50,000,000 barrels of crude oil to the United States. At the present time Mexico has a potential of at least 500,000,000 barrels' production a year, which could be moved to the United States if adequate transportation were available. And, furthermore, the resources of the oil deposits of South America have not been tapped as yet for use in the United States.

Importance of Oil Shales

In view of the above facts, the subject of oil shales has become important, and much is being written about it. Most of the literature, however, deals with statistics concerning the oil shales of a particular locality, and very few attempts have been made to co-ordinate the subject as a whole.

Almost all solids capable of giving up oil either by heat treatment, or by the use of solvents, have been

[1] W. C. Teagle, *Oil and Gas J.*, 11 (1913)

classified as oil shales, and although the writers make no pretense that a strict classification can be made, yet a treatment of the most important types of solids producing oil referred to as oil shales may help to clear the field a little.

The relations of these various types to one another, their possible mode of origin, their relation to other solid hydrocarbons and to petroleum, with a discussion of the economic distribution and treatment of oil shales, and the uses of their products, have been correlated by the writers.

Clays, Shales and Slates

The name clay is applied to argillaceous or sedimentary deposits still retaining enough moisture to be plastic. By loss of this uncombined water these clays pass into mudstones, shales and slates. When these fine-grained rocks are composed of sand or limestone sediments they are termed argillaceous sandstones or limestones. A shale is supposed to be a consolidated mud or clay in which the principal constituents are silicates of alumina. As soon as the consolidated clay begins to develop bedding planes and shows a tendency to split along the original laminæ the rock is termed a shale. Further, pressure, sometimes assisted by igneous intrustion, causes a partial change in mineralization, and the original bedding planes are superseded by a new direction of weak cohesion called slaty cleavage, and the resulting rock is called a slate. Pressure alone causes the colloidal particles in muds and clay to cohere, cementation seeming to be a minor factor. The extent to which muds and clays are converted into shales is therefore a function of the pressure. These clays and shales have the property of absorbing petroleum to a limited extent. The adsorptive property of clays and shales for oil has been shown to depend in part on colloid content, which in turn changes with chemical composition.

For comparative purposes Table I tabulates the inorganic content of clays, limestones, shales and similar substances. Some of the spent shales are relatively high in alumina content and may have economic value on that ground, but their importance will lie in the working out of satisfactory cements, clays for pottery, brick and paving material for streets by blending with suitable binders.

Origin of Petroleum

The theories as to the origin of petroleum can be divided into two great classes, namely, the inorganic and organic. The main support of the inorganic theory lies in the fact that hydrocarbons of the acetylene, ethylene and methane series can be produced by the hydrolysis of metallic carbides. The carbide theory has few adherents at the present time. The organic theory is divided into three classes, namely, animal, vegetable, and a combination of the animal and vegetable theories. Under the heading of animal origin of petroleum is the theory that the existence of petroleum is due to the decomposition of marine animals, such as fish, oysters, scallops and a microscopic organism called foraminifera, the latter being found in great quantities along sea coasts in beds hundreds of feet thick. The vegetable theory includes the formation of petroleum from seaweed, land plants and diatoms. The enormous quantity of kelp found along sea coasts lends support to the seaweed theory. It has been clearly shown by numerous investigators that coal is formed from land plants. It is possible that under different conditions petroleum would be formed from plants or that possibly oil was distilled from coal in nature, as may readily be done in the laboratory. It can readily be seen that all possible combinations of the animal and vegetable theory are possible, especially since the remains of animal and vegetable matter are found in the same strata.

Table I—Analysis of Clays, Limestones, Shales and Cannel Coal

Type	Per Cent				
	Silica	Alumina	Iron Oxide	Calcium Oxide	Magnesium Oxide

The organic matter laid down in beds is prevented from too rapid oxidation by an impervious seal of water overhead, and the formation of oil may be caused by magmatic intrusion under heat and pressure by a process of distillation or diffusion through porous mineral matter.

Oil and gas deposits always occur in higher parts of folds in the earth's surface called anticlines, domes and monoclines. The rocks composing these folds are sedimentary or water laid deposits, such as sands, sandstones, limestones and shales. Water occurs in the same stratum as the oil, but in a lower part of the fold. The oil does not occur in pools, but is retained in reservoirs consisting of coarse sands, porous limestones, sandstones and shales. These deposits retain the oil in the spaces between the grains and are capped, as well as underlaid, by impervious beds, thus preventing the escape of the oil. Some of these caps have been broken and replaced by layers of asphaltic and paraffin deposits left by the evaporation of the more volatile constituents. Such caps give us a hint as to the possibility of the formation of bituminous shales where conditions were such that simultaneous slow evaporation and oxidation of an asphaltic base oil impregnating a shale would leave a product such as is represented by some of our oil shales. This process may have gone on before or after the clay was consolidated into a shale, or the consolidation may have assisted the process.

Some Solid Hydrocarbons

No discontinuity is shown in passing from natural gas through liquid petroleum to solid asphalt and bituminous coal. The physical properties are progressive

in going from gases through liquids and viscous mixtures to solids.[2] All of this suggests a common origin. The solid hydrocarbons found in nature are known generically as bitumens and asphalts. "Bitumen is described as a naturally occurring mixture of native or pyrogenous hydrocarbons and their non-metallic derivatives, which may be gases, liquids or solids soluble in carbon bisulphide and benzol."[3]

The asphalt of Pitch Lake, described by Richardson,[4] is an emulsion of water, gas, bitumen and mineral matter. The gas consists mainly of hydrogen sulphide and carbon dioxide. The analysis of purified Trinidad bitumen is as follows:

	Per Cent
Carbon	82.33
Hydrogen	10.69
Sulphur	6.16
Nitrogen	0.81

Investigation showed that the hardness of bitumen increased with the sulphur content and indicated that sulphur was probably active in hardening the bitumen. Among the most abundantly occurring solid hydrocarbon materials in the United States are gilsonite, tabbyite, wurtzilite, ozokerite and rock asphalt. These substances have varied uses in the industries. Gilsonite is used for paving, insulation, mineral rubber, roofing and water proofing. Tabbyite is used in making mineral rubber; ozokerite or mineral wax, which also occurs in Galicia, Austria, is used in making electrical insulators, and as a substitute for bee's wax. Rock asphalt, a sand conglomerate cemented by bitumen, is used for paving. Bardwell, Berryman, Brighton and Kuhre[5] have compiled some interesting data on the properties of these hydrocarbons. Some of these data are tabulated in Table II.

TABLE II

	Trinidad	Gilsonite	Tabbyite	Wurtzilite	Orokerite
Bitumen soluble in CS	60 36	99.64	94 63	10 83	99 46
Organic matter insoluble in CS	3 94	0.0	0.72	87 68	0 50
Inorganic or mineral matter	35.70	0.36	4 65	1 50	0 50
Loss on ignition	61 30	99.64	95 35	98 50	99 96
Fixed carbon	36.69	43.13	37 45	35 60	10.03
Sulphur	4 22	0 52	1 21	4 00	0 29
Total volatile at 400 deg. C	27.61	56 51	57 90	61.58	87 93

In all cases: streak colored brown, and fracture concholdal.

Wurtzilite was also found to be very little soluble in naphtha and carbon tetrachloride. It differed from the others by being insoluble in its own distillate and in the distillates of the others.

The case of wurtzilite, which resembles in composition the other hydrocarbons investigated, but differs from them in being practically insoluble in carbon bisulphide, etc., is not an isolated one. Cannel coal[6] and the Scottish shales are of the same nature, showing slight solubility in certain solvents.

In dealing with the origin of these solid hydrocarbons, experimental and geological evidence would tend to show that their source is practically the same as that of petroleum. Some of the best experimental evidence relating to the formation of these solid hydrocarbons is collected in *Bulletin* 616, issued by the United States Geological Survey, 1916. Some of these data, with original references, are given below.

Engler[7] distilled menhaden oil (fish oil) at temperatures varying from 320 deg. C. to 400 deg. C. and a pressure of 10 atmospheres. He obtained a distillate resembling petroleum, which upon being fractionated gave various type hydrocarbons.

C. W. Day[8] found that upon distilling fish (using fresh herring) a product formed which upon redistillation yielded a residue closely resembling gilsonite. With fish alone the final product was more like elaterite, a natural product closely resembling wurtzilite. Distillation of wood gave a similar residue. Thus natural asphalts were obtained resembling the natural substances and containing nitrogen similar to ordinary asphalt.

A specimen of albertite, an oil shale from New Brunswick, Canada, known as "paper shale," was examined by the writers and found to contain distinct fish remains. This shale was a highly indurated and laminated type, which seemed to be impregnated with bituminous material only along the bedding planes. Adjacent to this was a shale impregnated through and through with the bituminous material, and on whose surface was some pure bituminous material free from kaolinitic matter. The evidence in this particular bituminous substance may be a fish oil residuum.

Ells[9] in describing the oil shales of New Brunswick stated that they are often rich in fish remains. Many other writers cite the presence of fish remains in oil shales, which confirms the animal origin of both solid and liquid hydrocarbons.

This does not exclude the vegetable theory, since vegetable oils[10] likewise yield hydrocarbons upon destructive distillation, and the case of wood has been cited. The nature of liquid and solid hydrocarbons is thus seen to depend on the source, paraffin base oils being thought to be of vegetable origin and asphaltic base oils of animal origin.

OIL SHALES

It has been shown that shales, sandstones and limestones are of sedimentary origin. These rocks grade into one another and shales are found which contain considerable calcite and quartzite either in the original formation or by replacement. All of the rocks are capable of absorbing petroleum, and the resulting rocks are known as oil shales, oil sandstones and oil limestones. Shales which are simply impregnated with oil are not the type which are usually referred to in the literature as oil shales. They are, however, equally entitled to be called oil shales, and, as has been suggested previously, may really be the parent of the present day oil shale deposits.

Rocks referred to as oil shales vary greatly in character. In some types, such as paper shale, the bedding planes are prominent, while in others the laminæ are only developed upon retorting. In some cases the shales are not impregnated with the bituminous material, but the material seems to have simply forced its way along

the bedding planes. Gilsonite occurs in this manner, and albertite in some cases.

In a number of instances the oil and bituminous material contained in oil shales may be dissolved out by carbon bisulphide, benzol and similar solvents. The Scottish shales are, however, not of this character, and wurtzilite,[11] which has been found to be identical with the oil shales of the Green River formation in Western United States, has been shown to be only slightly soluble.

All of these types produce oil upon heat treatment, but[12] those which are insoluble have been classified as containing an oil producing substance which is neither bitumen, petroleum or resin. Crum Brown first employed the term kerogen to denote this substance. A kerogen shale is a shale containing kerogen as distinguished from one containing crude petroleum or bitumen.

Microscopic[13] examination of Autun boghead coals and New South Wales torbanite has shown the presence of irregular shaped yellow bodies, not disturbing the lamination, but sometimes extending across it. It was concluded that these bodies were introduced from some outside source, although Renault and Bertrand[14] looked upon them as being originally derived from a gelatinous algæ, and formed in situ.

Some of the "blaes" [15] (Scottish shales producing very little oil) are carboniferous, but on examination are found not to contain kerogen. In general it has been found that the amount of oil produced from this type of shale is proportional to the amount of these yellow bodies, called kerogen. Thus kerogen seems to be present in only the shales found in anticlinal regions. Examination of a section of this oil shale under the microscope brought out its fine grained and laminated character. The darker shales are more opaque than the lighter, and are consequently harder to examine. Varying quantities of vegetable debris are also present, the darker specimens usually containing more than light colored specimens.

Distribution and Mode of Occurrence

Oil shale occurs in economic deposits in the United States, Canada, Nova Scotia, Scotland, France, New South Wales, Australia, New Zealand, Tasmania, Spain, Austria Hungary, Turkey, South Africa, Brazil and Italy. The most important deposits are in the United States, Canada, Scotland and France.

The Scotch shales as described by Ells[16] are of a chocolate brown color and soft, being easily cut with a knife. They are free from gritty matter. They vary in oil content as well as in ammonium sulphate in different bands, and even in parts of the same bed. The shales approximate what is known as paper shales, and the beds vary in thickness from a few inches to 15 ft., being interstratified with blue-grey portions and hard calcareous or siliceous bands. In[17] area the shale beds cover an extreme length of about 24 miles.

Scotch shales used for oil are known by the terms "plain" and "curly." These are associated with a less rich portion known under the name of "blaes." The curly shale is the more valuable, a larger percentage of hydrocarbons making it softer and more crumbly and easier to mine. "Blaes" on weathering pass into muds. Rich shale, however, remains unchanged by exposure to weather conditions even for years.

The strata are often thrown into folds which bring different portions to the surface at various points. Most of the mining is underground, however, and some of the Scotch workings have been worked to a depth of 1000 ft., the mining being carried on after the fashion of mining bituminous coal. Roofs are supported with timber, props and pillars. A regular system of roads, driveways and drifts has been installed.

The oil shales of New Brunswick[18] are the most important of the Canadian oil shales. The Scotch shales are more papery than the New Brunswick shales, the shaly character of the latter being developed on retorting. The New Brunswick shales burn easily, only the large per cent of ash making it unfit for economic use at present. The types corresponding to the "curly," "plain" and "blaes" of Scotland are found in New Brunswick.

The oil shales of New Brunswick vary greatly in character, ranging from a thin bedded brownish or blackish grey, sometimes quite flexible and elastic, and usually known locally as paper shales, to massive bands of black, tough shales which occur as interstratified beds in the formation as a whole. While the greater part of these shales are bituminous the black massive beds which range in thickness from 3 to 7 ft. are much richer in ammonia, gas and crude oil than the great mass of thinner shales. The sands above these shales have been known to contain small quantities of oil, but as far as is known the oil shales do not contain any. The darker shales have an abundance of plant and fish remains.

The principal economic deposits of oil shale in the United States[19] lie in the Green River formation in Colo rado, Utah and Wyoming. There are deposits also in the Eastern[20] part of the United States, underlying the coal fields, cropping out in Alabama, Indiana, Pennsylvania, Tennessee, Virginia, Ohio, Kentucky and Illinois.

Winchester[21] has made an exhaustive examination of the Green River formation, and has made an extensive report on the Western oil shales. The Green River formation has a maximum thickness of 2,600 ft., the middle part of the formation containing the beds most rich in oil-producing shales. This formation consists principally of shale, but contains beds of sandstone, with oolite being present in some parts.

In Colorado the shale area includes probably twenty townships, being 50 miles long and 20 miles wide. In Utah the area may be even greater. As has been mentioned before, the government has reserved 3,692,036 acres of land in this area as oil land for the use of the navy.

These shales are for the most part insoluble in carbon bisulphide, benzol and similar solvents, and have been said to approximate wurtzilite in composition. The mineral matter in which the oil producing substance is held is a smooth non-siliceous clay containing a small amount of carbonate of lime.

In Colorado[23] it is estimated that the shale deposits are capable of yielding 20,000,000,000 barrels of crude oil, giving upon refining 2,000,000,000 barrels of gasoline, and those of Utah will probably produce an equal amount. The Colorado shale will probably also produce about 300,000,000 tons of ammonium sulphate, a substance useful as fertilizer and for the production of nitric acid for use in explosives. At many places in Colorado and Utah the rich shale has only a light overburden, and could be mined with a steam shovel, in this respect possessing a great advantage over the method of mining in Scotland and France. But there are particularly tough layers of shale which wear out steam-shovel teeth rapidly, even those of manganese steel, which will be an important factor in the cost of mining. However, in Scotland some pits and shafts are 1000 ft. deep, which factor is not present in the Colorado and Utah deposits.

The principal deposits of shale in France are in Autun and Buxieres. The former has been regularly exploited since 1862 and the latter since 1858. The oil shales in these two principal sections of France occur for the most part interstratified with calcite and quartz strata; the shale being approximately two meters in thickness. The Autun deposits cover about 18,000 hectares (36,000 acres), the mining of which is underground. The oil shale runs fairly uniform in the formation of oil and by-products.

Method of Production and Products

The distilling of oil shales has been known as early as 1694, when Eele, Hancock and Portlock made "oyle from a kind of stone" in England. The details of retorting practice in the various countries have been very well written up by the following experimenters. The French oil shale industry has been balanced against the practice in vogue in Scotland with statistics of production by Chosson,[24] Chesneau[24] and Aron.[25] The industry in New South Wales, Queensland, has been written up in the report of Atkinson[26] and Ball,[27] with statistics for New South Wales from 1865 to 1914. The methods of retorting oil shale past and existent at the present time, with statistics, yields of products in Scotland and Canada, have been covered in detail by Ells,[28] Baskerville,[29] Redwood,[30] Bacon and Hamor.[31]

Outline of Scotch Practice

The following is the merest outline of oil-shale practice in Scottish use to-day. For greater detail the reader is referred to the above references. An oil-shale plant consists in the main of shale-breaking machines, retorts, condensers, ammonia and oil scrubber, fire and steam stills, acid agitators, filters for lubricants and wax, sweat pans, refrigerating house for wax and low cold test lubricants, receiving tanks, gas tanks for burning the gas made directly under retorts, ammonium sulphate house, boiler house, pump house and laboratory.

The oil shale in small pieces is passed by means of hutches into iron retorts varying in capacity from one-half to two tons per twenty-four-hour day. A number of types of retorts are in use, varying considerably, some keeping the mass of shale in continuous movement; others simply heating the mass, and dumping the charge when no further gases pass over to the condensers. The temperature of retorting varies, dependent upon the type of shale used, from 400 deg. C. to 700 deg. C. The temperature control is highly important, for upon this factor depends the type of hydrocarbons formed and amount of ammonia, the latter forming in greater quantity when steam is passed into the system toward the end of the reaction. The products resulting from retorting the oil shale pass through air or water-cooled condensers and the uncondensed gases are drawn into exhausters. From the exhausters the uncondensed gas is led through water and oil scrubbers to remove ammonia and light hydrocarbons. The scrubbed gas may be used directly for fuel with a "booster" attached or may be passed to a storage gas tank. The ammonia liquor is distilled and the gas passes through sulphuric acid forming ammonium sulphate crystals which are purified for market or sold dry without purification, dependent upon the use.

The usual commercial products resulting from the retorting of oil shale are crude oil, motor fuel, naphtha, burning oil or kerosene, gas or fuel oil, lubricating oils, paraffin wax, still grease, coke and ammonium sulphate. Table III gives the products and yields for the year 1916 of 3,500,000 tons of oil shale retorted in Scotland.

Table III—Scottish Shale Products Obtained and Products Marketed in 1916 from 3,500,000 Tons Oil Shale

	Gallons	Per Cent Basis Oil Recovered	Approximate Specific Gravity	Approximate Beaumé Gravity

As ammonia (tons	16,000	0 44		

The average cost per ton of oil-shale mining and retorting was $2.00, and the net profit per ton oil shale retorted $0.85. In the year 1916, 23 gal. of oil and 38 lb. of ammonium sulphate as an average were produced for each ton oil shale retorted.

The Comparative Yields of Oil and Ammonium Sulphate from Retorted Oil Shale

The vital figures in oil-shale mining are those which will give average gallons of oil and pounds of ammonium sulphate per ton of oil shale retorted. For upon the yields of the crude oil and sulphate depends the question whether a plant will be remunerative financially. Winchester[32] in his important contribution to oil shale information has shown that of 132 samples retorted the yields of oil per ton of shale ranged from 0.31 to 90 gal., and the pounds of ammonium sulphate from 0.4 to 12.69 dry retorted. He has worked out a con-

version factor when the shale is steam-distilled for ammonia which brings the ammonium sulphate values from one to thirty-two pounds per ton shale retorted.

In Table IV the writers have computed the average of fifty-one samples retorted Colorado shale, which gave an oil gallonage of 16.2. Of the fifty-one samples twenty-nine were tested for ammonium sulphate with an average of 7.6 lb. per ton of shale. For the state of Utah the average of thirty-eight samples under similar conditions gave 25 gal. of oil and 5.3 lb. of ammonium sulphate per ton. Wyoming gave 16.4 gal. oil and 6 lb. of ammonium sulphate per ton as an average of forty-two samples retorted. The oil shales of Utah indicate a 40 per cent greater yield of oil per ton than the states of Colorado and Wyoming. Twenty samples of the Colorado shales were tested for the cubic feet of gas per ton of shale retorted, and the average was found to be 2705.

The distillation analysis of nine samples of shale oil from divergent geographic locations have been averaged. The gasoline cut percentages ranged from 6 to 12; the kerosene cut from 28.5 to 49 and paraffin from 1.63 to 7.70, while the unsaturated hydrocarbon in the kerosene cut ranges from 55 to 71 per cent. Although an average over the samples of 9.6 per cent with a Beaumé gravity of 47.9 for the gasoline cut is noted, this is quite different from having 9.6 per cent of an oil which will be suitable for internal combustion engines. It is highly questionable whether in refining and redistilling the above gasoline cut into a motor fuel suitable for internal combustion engines that anything like 9.6 per cent of marketable motor fuel would be obtained from 100 gal. of oil shale as typified by the samples analyzed. The Scottish oil-shale industry for 1916 marketed 600,000 gal. of motor fuel of 59.2 Beaume gravity, which was 0.7 per cent of 80,500,000 gal. of shale oil produced.

TAPLE IV—THE AVERAOE GALLONS OF OIL, POUNDS OF AMMONIUM SULPHATE AND CUBIC FEET OF GAS PER TON OF OIL SHALE RETORTED FROM UTAH, COLORADO AND WYOMING[32]

G. H. Ashley[34] of the Geological Survey has reported upon the black shale of Eastern United States. The lowest yields were noted in West Virginia of 1.4 gal. oil and the maximum of 27.6 for the state of Pennsylvania per ton black oil shale retorted. The latter figure compares more than favorably with the average of Utah and gives a 42 per cent higher oil yield than the states of Colorado and Wyoming.

The data are compiled in Table V.

At least three important factors enter into the profitable mining of black oil shale:

1. Where the out croppings permit of steam shovel use at a minimum of cost.
2. Where the coal is overlaid with oil shale which can be mined at the same time.
3. Where oil shale must be removed to mine the coal and can be retorted at same time.

Ashley has stated that the total area of southeastern Indiana is underlain with shale bearing oil, which contains 100,000,000,000 barrels of oil.

TABLE V—THE AVERAGE GALLONS OF OIL PER TON OF BLACK SHALE RETORTED FROM THE EASTERN PART OF THE UNITED STATES[34]

The oil shale investigation of Canada has been covered by Dr. R. W. Ells of the Department of Mines, Canada, in a thorough manner. These show a much higher yield of oil and ammonium sulphate than those investigated in the United States. The average yield of oil for forty-four samples for Canada is 34.9, while an average of 131 samples in the United States gave 19.2 gal. per ton. The yield of ammonium sulphate for Canada gave 51.3 lb. and 16 lb. for the United States. Table VI tabulates the data in detail.

TABLE VI—THE GALLONS OF OIL AND POUNDS OF AMMONIUM SULPHATE PER TON SHALE RETORTED. EASTERN CANADA[35]

Since cannel coal is analogous to some extent to oil shale, for comparative purposes some work by Ashley[37] and Ingram[38] on cannel coal has been given, the data of which are shown in Table VII. An average of thirteen samples gave 38.8 gal. of oil, which is 100 per cent higher than the average yield of Utah, Colorado and

Wyoming. This oil from distillation analysis compares favorably with the oil from shale. The geological data as to the size and extent of cannel coal deposits in the United States are not obtainable to any extent. In the Caney Creek[39] region of Kentucky there is a workable section of cannel coal of 2000 acres. The writers have calculated that this area would produce approximately 10,000,000 barrels of oil and 11,000,000,000 cu. ft. of gas.

[2]Ingram Bulletin School of Mines University of Missouri, 1917.

The oil-shale industry in France began in 1830 with a commercial process perfected by Selligue in 1839. The industry flourished until 1864 when it received a shock similar to Scotland, due to the introduction of American petroleum in 1864. American and Russian refined petroleum products practically paralyzed the oil-shale industry from which it took a long time to recover. The oil-shale retorting practice of France was for many years in oil productivity much lower than Scottish practice. The French practice was to retort at a relatively low temperature, no steam being used during cracking for increasing the yield of ammonia. It was not until 1903 that the Young and Fyfe retorting method was installed in French practice. The advantages of this method over the older one were that it allowed of a saving of fuel and increased the ammonia and oil yield. In Table VIII the gallons of oil per ton of oil shale retorted over a period of years is given. The immediate effect of the Young and Fyfe method of retorting is shown clearly in the year from 1903 to 1904, where the oil yield jumped from 18.1 to 20.7 gal. of oil per ton of shale.

Aron[40] states that by the introduction of steam and higher temperatures in oil-shale retorting practice in France a saving of 80 centimes per hectolitre of oil was accomplished. In the Autun and Allier districts in 1893 there were 96 plants in operation with 414 French retorts and no Scotch; while in 1905 of the 74 plants in operation there were 232 Scottish retorts and only 60 French. It is more than likely that at the present time Scottish retorting is in vogue in all plants in France.

The production over a series of years as shown in Table VIII gives a steady increase in gallonage of oil per ton of shale retorted due to improved methods of retorting. But, the amount of oil produced per year is negligible in comparison to the oil requirements of France and also shows a decline in oil shale retorted. Edouard[41] in 1915 stated that "France, which does not produce petroleum at all, is obliged to get from foreign countries all she consumes." In the *Annales des Mines* for the latter years no statistics of oil shale or products resulting therefrom are given. Beranger[42] in July, 1917, proposes that France coke coal for the production of gas and oil, the latter to be used for the industries and fuel for ships. He emphasizes the utter dependence of France in peace as well as war times upon foreign countries for petroleum products and advises the government to seek oil production in Persia and other countries so as to preserve the economic life of France. The needs of France in this respect are 30,000 tons of gasoline for the army and 20,000 tons for the interior per month. This amounts to 225,000,000 gal. of gasoline a year as the needs of France. The total oil produced from shale was in round numbers 3,700,000 gal., of which probably 2 per cent was gasoline or 74,000 gal. of gasoline, which is practically a negligible quantity in comparison to the 225,000,000 gal. gasoline required yearly in France.

TABLE VIII—TONS AND OIL PRODUCTS FROM FRENCH SHALE

Year	Shale Retorted (in Tons	Oil Produced (Hectolitres	U S Gallons	U S Gallons per Ton
1893	186,040	97,820	2,584,111	13 9
1894	185,617	94 457	2,495,271	13 6
1895	216,079	106,958	2,825,410	13 1
1896	178,571	109,415	2,890,795	14 9
1897	190,302	114,703	3,031,094	15 9
1898	181,988	109,903	2,904,302	16 5
1899	209,125	131,865	3,483,478	16 7
1900	220,609	134,191	3,544,923	16 1
1901	208,070	131,612	3,476,794	16 7
1902	212,955	141,821	3,746,459	17 6
1903	185,280	136,136	3,596,304	18 1
1904	184,030	139,826	3,693,783	20 7

The oil shale industry in New South Wales[43] is approximately sixty years old. The method of retorting is the Scotch one, which up to the present is the most successful in use. The industry in New South Wales has declined markedly in the last twenty years, droping from 59,426 tons in 1895 to 17,425 tons oil shale retorted in 1916. The amount of oil produced per ton of shale retorted was not obtainable, but on the assumption of 20 gal. of oil per ton of shale, 348,500 gal. of oil would be produced. The data in Table VIII-A expresses the tons of oil shale retorted from 1865 to 1916 and the value per ton in pounds sterling.

TABLE VIIIA—TONS OF SHALE RETORTED IN NEW SOUTH WALES, YEAR 1865-1916

Year	Quantity, Tons	Total Value in Pounds Sterling
1865	570	2,350
1875	6,197	15,500
1885	27,426	67,239
1895	59,426	75,218
1905	38,226	21,246
1915	15,474	12,890
1916	17,425	17,772

Chihuahua Smelter Re-opens.—The American Smelting and Refining Co., reopened its smelter near Chihuahua, Mexico, on March 31st, after a shut-down lasting since November 1915. About fifteen Americans and 500 Mexicans are at work, which number will be doubled shortly if conditions seem to warrant the step. The Americans are housed in Chihuahua City, and taken to and from work in automobiles.

A Process for Deodorizing Fatty Oils

By WALTER P. SCHUCK*

IN THE preparation of vegetable and animal fats and oils for commercial use a large portion of these substances is treated by some deodorizing process in the course of refining. According to Lewkowitsch,[1] one of the earliest methods of deodorizing oils was by heating them to a high temperature. This method will destroy the characteristic odor of many oils if the temperature employed is high enough. Many recent attempts have been made to apply this method to the deodorization of fish oil on a commercial scale in Europe. While the characteristic odor of an oil may be destroyed by heating, a more or less burnt or other unnatural odor is usually developed and therefore the method has not been used for the preparation of edible oils.

The process commonly used to deodorize an oil without changing any of its properties except odor and taste, consists in blowing live or superheated steam through the oil for a sufficient length of time to secure the desired result. This process is effective only on those oils whose odor and taste are due to the presence of small quantities of substances that might be classed as impurities and are carried away by the steam. That is to say, if oils are considered as essentially mixtures of the glycerides of fatty acids, the steam-deodorizing process is effective only when the characteristic odor is not due to one of the constituent glycerides. Fortunately the steam-deodorizing process has made it possible to obtain odorless and pleasant tasting oils from nearly all vegetable oils that were desired for edible purposes. Fish and marine animal oils, however, cannot be completely and permanently deodorized with steam.

Despite the wide application of the steam-deodorizing process it is well known that the conditions to which this process subjects the oil are such as to promote decomposition. The action of hot water or steam has been used to hydrolyze fatty oils into glycerine and fatty acids, high pressure being advantageous in the process. This pressure is not present when deodorizing with steam. The contact of steam and oil at a high temperature does exist and tends to set free the fatty acids. This does not cause the oil to take on a rancid taste or smell immediately; it does tend to develop rancidity later.

About two years ago while the author was carrying on some experiments on the catalytic hydrogenation of naphtha-extracted corn oil, he observed that a sample which had not been purified sufficiently to allow the catalyzer to act and which had not hardened, nevertheless was rendered odorless and palatable by the action of the hydrogen on the oil containing a catalyzer in suspension. Although no appreciable hardening had taken place, the improvement in odor and taste was so marked that a fresh sample was treated under identical conditions except that no catalyzer was present. This sample proved to be equal in odor and taste to that treated with hydrogen in the presence of a catalyzer and thus showed that the catalyzer did not function in the removal of odor from the corn oil.

Knowing that fish oils had not been deodorized unless they were at least partially hydrogenated in the presence of a catalyzer, the treatment with hydrogen only was next tried on a fish oil. After several attempts the proper conditions were ascertained and a sample of fish oil was produced that was odorless and palatable.

The method of deodorizing any oil or fat by this process consists of blowing hydrogen, or a gas whose principle constituent is hydrogen, through the heated oil and allowing the hydrogen with the entrained vapors from the oil to escape freely from the containing vessel until the desired result is obtained. In the commercial application of this process, the fatty acids and other fumes are condensed and washed from the hydrogen which is thus completely purified and used over again. The entire apparatus should, of course, be filled with hydrogen to the exclusion of all oxygen from the air at the time of its first use. Thereafter each new batch of oil is introduced and the deodorized oil withdrawn through pipes so that no air enters the apparatus. A means of drying the hydrogen is provided in the gas-purifying system if the oil being treated contains appreciable quantities of water.

Chemical and Physical Means Used

The means whereby the deodorization is accomplished in this process are both chemical and physical. The iodine value of the oil treated is lowered to a certain extent and the amount of lowering is proportional to the original iodine value. The process can be successfully operated when the oil comes in contact with nothing but glass and hydrogen during treatment. As far as I have been able to ascertain, glass cannot act as a catalyzer and assist the chemical union of hydrogen with the glycerides of unsaturated fatty acids. Nevertheless I have conducted numerous tests in which an oil was subjected to the action of a stream of hydrogen in a glass distilling flask and have found that the oil so treated is more nearly saturated with respect to hydrogen than the untreated oil as is shown by the lowering of the iodine value. This would indicate that a small but effective portion of the hydrogen actually combines with the oil. This was suspected from the fact that fish oils treated by this process are as effectively and permanently deodorized as they are when subjected to catalytic hydrogenation. A trace of the oil and practically all of the free fatty acids contained in it are mechanically carried away from the oil during treatment. Hence the assumption would not be justified that hydrogen is actually combined with the oil just because the iodine value is lowered. The iodine value might be lowered also if the material carried away was of a more highly unsaturated character than the untreated oil.

To determine more accurately what takes place during

*Vice-president, Superior Oil and Process Co.

[1]Volume 3, page 19.

this process, a number of experiments were carried on in which two samples of each oil were subjected to the action of a stream of pure hydrogen and pure nitrogen, respectively, under identical conditions. The fumes carried away from the oil were condensed from the gas and at the end of the experiment practically the entire weight of the oil subjected to treatment was accounted for in the weight of oil remaining in the flask plus the weight of condensate. The iodine values of the remaining oil and of the condensate were determined in each case. It was thus found that in every comparative test the total iodine absorptive capacity of the remaining oil plus condensate was less when hydrogen had been used than when nitrogen had been used. In other words, the iodine value of the total oil body in contact with hydrogen was in every case lower than the iodine value of the oil body in contact with nitrogen, although no metal that might have acted as a catalyzer was present. It would seem from these experiments that my deodorized oil so closely resembles an oil deodorized by catalytic hydrogenation because the two processes are essentially the same; that is, the deodorization taking place in this process is at least partly due to hydrogenation. It has been claimed by Tsujimoto[2] that the odor of fish oils is due to the glyceride of clupanodonic acid which has four unsaturated carbon atoms. As this is only a minor constituent of the oil and since the introduction of hydrogen at only one double bond would change it to a different and probably inodorous compound, it is easy to comprehend how a slight addition of hydrogen to fish oil can make it permanently inodorous.

In the comparative tests above described it was found that nitrogen left the oils with a burnt taste and in some cases with only part of the characteristic odor removed. The free fatty acids remaining in the nitrogen-treated oils is about three times as much as in the hydrogen-treated oils.

An interesting and valuable feature of this process is the rapidity with which free fatty acids are removed from the oil by the stream of hydrogen bubbling through it. These fatty acids begin to pass from the oil at about 240 deg. C. and can be removed from most oils to within 0.15 per cent in 20 min. at 275 deg. C. Cocoanut oil containing over 14 per cent free fatty acids has been purified by this process to a free fatty acid content of 0.12 per cent. A fish oil containing 5.14 per cent f.f.a. was purified by this process so that it contained only 0.14 per cent f.f.a. and the total shrinkage during the hydrogen treatment was only 6.10 per cent. The removal of free fatty acids took place during deodorization. It will be seen that the loss in purifying was only 1.10 per cent more than the loss due to actual removal of free fatty acids. The free fatty acids so removed are condensed from the current of hydrogen and recovered uncombined so that soap can be made from them by neutralizing with soda ash.

In regard to the keeping qualities of oils and fats treated by this process it can be stated that oils so treated stay sweet very much longer than steam-deodorized oils. An exact comparison cannot be made because the oldest samples (treated 21 months ago) are still free from rancidity. A sample of cocoanut oil was treated by this process at the same time that some of the same oil was deodorized with superheated steam in a factory. Both samples were put in clean tins with lids loosely laid on, then alternately kept in a warm place where the oil was liquid during the day and in a cool place at night for four months. The steam-deodorized oil became rancid in a few weeks and was very poor in quality in two months. The hydrogen-deodorized oil was pleasant to taste after four months' storage under the described conditions and is still so. The keeping qualities of hydrogenated oils are well known and since the keeping qualities of oils deodorized by this process are due to the action of the hydrogen, it is not surprising that they should be stabilized and rendered free from the tendency to become rancid.

Commercial Possibilities

Among the commercial possibilities of this process the purifying of fish oils so as to render them edible is of prime importance. Even the deodorization of fish oils for technical purposes is a matter of interest. The fish oils deodorized by this process cannot be made to smell of fish by subjecting them to heat or any other action that oils are usually subjected to. While this process cannot take the place of catalytic hydrogenation of fish oils in every case because the oil is not hardened, it is very much cheaper to operate. Fish stearine which is naturally a solid fat at ordinary temperatures can be made into an acceptable cooking fat at very low cost by this process.

Fats which have been burnt from continued use in cooking and have absorbed the odor of fish, onions, garlic, etc., can be rendered perfectly bland and neutral by this deodorizing process. Likewise garbage- and rendering-works grease can be purified so that it is neutral and free from objectionable odor. This latter class of fats usually contain substances that "poison" a catalyzer and therefore are not easily deodorized by catalytic hydrogenation. Since this process does not involve the use of a catalyzer such substances do not interfere.

In the treatment of castor oil this process is of value for two purposes. The medicinal castor oil can be rendered entirely free from its characteristic odor and taste while still retaining its medicinal properties. The lower grades which have a high free fatty acid content can be treated for the reduction of the free fatty acid content and thus render them more acceptable for the lubrication of machinery.

Certain vegetable oils such as soya bean oil are not readily deodorized with steam but are rendered bland and palatable by this process.

It is not to be supposed that every crude fatty oil can be treated by this process just as it is found in commerce nor that low grade greases can be made into light colored, clean fats without more shrinkage than the removal of the free fatty acids would entail. The solid matter, such as particles of cellular tissue, should first be removed by clarification and filtering in order to get the lightest colored product. The total shrinkage will therefore depend on the amount of impurities present and the commercial possibilities can only be determined by a study of the oil or fat under consideration.

The use of the process here described is protected by U. S. Patent No. 1260072 as well as other applications for patent on file and by applications for patent on file in foreign countries.

Synopsis of Recent Metallurgical and Chemical Literature

Experimental Carbon Cell

At the recent meeting of the American Electrochemical Society a paper was read by Dr. S. ALBERT REED of New York City. A primary battery was described in which the electrolyte is fused borax containing manganese dioxide, the negative pole is broken carbon in contact with a graphite grid and floating on the melt, while the positive poles are strips of gold foil. The carbon is kept inside a cylindrical shell of siliceous material (a sawed-off crucible), while the melt is contained in a shallow clay roasting dish, in which the cylinder stands. The air oxidizes the electrolyte in contact with the outer gold strips, while the carbon reduces the electrolyte inside. Mixtures of CO_2 and CO are produced at the anode. The voltage averages 0.8.

Analysis of Ferro-Silicon

Another paper at the convention was on the "Commercial Analysis of Ferro-Silicon" by EARL M. ANGER, research chemist of the Chile Exploration Co., New York City. The author said he had read with much interest papers by a number of writers on the commercial analysis of ferro-silicons of various grades. Nearly all gave long, tedious methods, and not all of the necessary accuracy. Some writers determine several elements and then call the balance silicon. There are several elements which often occur in ferro-silicon of these grades when manufactured from iron ore or iron cinders, which are entirely neglected in this calculation. Any one of these elements may at times contaminate ferro-silicon up to 1 per cent. He then gave personal notes and experiences in the commercial analysis of electric furnace ferro-alloys for carbon, manganese, phosphorus, phosphorus evolved as phosphene, sulphur, iron, titanium, calcium, magnesium, aluminium, barium, and silicon; with advice on sampling. Many samples which he examined contained 0.1 to 0.5 per cent barium.

Electric Steel Castings

In a paper on this subject read at the recent meeting of the American Electrochemical Society by R. F. FLINTERMAN, the author said in part:

"During past months we have been experimenting along this line and wish to refer briefly to some wonderful tests we have been getting from vanadium steel. These tests have been obtained repeatedly, so that we are confident that we can reproduce them commercially.

"The tests we refer to are the following:

	No. 1		No. 2	
Ultimate strengtb.	102,000 lb.	74 kg./sq. mm.	103,800 lb.	74 kg./sq. mm.
Elastic limit.	81,500 lb.	57 kg./sq. mm.	84,000 lb.	59 kg./sq. mm.
Elongation in 2".	23 per cent.		21 per cent.	
Reduction in area.	48 per cent.		47 per cent.	

"There is just one more point which I desire to bring to your attention. In the discussion of my paper before this Society in May, Prof. J. W. Richards spoke in part as follows[1]:

"'Regarding the general question of the fitness of electric furnace steel for steel castings, for the information of the Naval Consulting Board I sent a questionnaire to about forty or fifty of my friends in the steel business, asking how a better class of steel castings could be obtained. About nineteen out of twenty of these answers were that if they would specify electric furnace steel for their castings that, other things being equal, there was a far better chance of getting a fine casting from electric furnace steel than from any other class of steel.'

"This statement of Prof. Richards sounds strangely prophetic, when read at this time in the light of what has happened since these words were spoken. Referring to our own experience, we are furnishing considerable quantities of army castings under Class No. 2 and No. 3 specifications, and are also making navy castings under Class 'B' specifications, and are having little trouble in meeting these specifications.

"We do not want to give the impression that these results are being obtained without any particular effort on our part, for quite the contrary is the fact. The heats are held for analysis before pouring, and every possible effort is made to have carbon and manganese where we desire them, before the heat is poured. Annealing is carefully carried out in new ovens recently installed, and here again every care is taken to see that annealing is exactly what we have planned it to be.

"The result of these precautions is that we are passing army and navy tests regularly. We do not hesitate to say, however, that with the same precautions we would fail on many of the tests were we using converter steel. At least that was our experience when we made converter steel, and it is our belief that many converter foundries are having this same trouble at the present time.

"The tests that we are obtaining are interesting in one way. They rather emphasize the fact that the specifications were not written for electric steel. For instance, Class No. 2 army specifications—

	Call for		We obtain	
Ultimate strengtb.	75,000 lb.	53 kg./sq. mm.	75,000 lb.	53 kg./sq. mm.
Elastic limit.	35,000 lb.	25 kg./sq. mm.	40,000 lb.	28 kg./sq. mm.
Elongation in 2 in.	15 per cent.		20 per cent.	
Reduction in area.	20 per cent.		30 per cent.	

"In the same way Class 'B' navy specifications—

	Call for		We obtain	
Ultimate strengtb.	60,000 lb.	42 kg./sq. mm.	65,000 lb.	46 kg./sq. mm.
Elastic limit.	27,000 lb.	19 kg./sq. mm.	35,000 lb.	25 kg./sq. mm.
Elongation in 2 in.	22 per cent.		30 per cent.	
Reduction in area.	30 per cent.		40 per cent.	

"In addition to the above, a 120-deg. bend test is required, which usually shows a bend up to 170 deg. or 180 deg.

"This army and navy steel-casting experience is really a great education for many of the steel foundries, and is bound to have a marked influence upon the industry after the war. Instead of a statement of hoped-for qualities, competition will demand physical test coupons, which must stand certain tests, and the casting will be accepted or rejected on the basis of these tests. It is needless to add that castings sold under such an arrangement must necessarily be of a uniformly higher grade than the average run of steel castings now sold."

[1]Trans. Am. Electrochemical Soc., 1917, 31, 80.

Personal

Mr. R. E. Parks, assistant general manager of the Aluminum Company of America, Maryville, Tenn., has been promoted to the position of general manager of the company's plant at Vadin, N. C.

Mr. John Joseph Carty, Colonel, Signal Corps, U. S. Army, was the recipient of the Edison medal awarded by the American Institute of Electrical Engineers on May 17, 1918.

Mr. George B. Hogaboom has been granted a leave of absence by the Scovill Manufacturing Company, in order to accept the appointment as electroplating advisor for the Bureau of Standards. He entered on his new duties May 15.

The following changes are announced in the Department of Chemistry in the College of the City of New York: Assistant Professor F. E. Breithut, who has already been granted a leave of absence for the duration of the war, has been commissioned as Captain in the U. S. Army, and has already reported for duty. Dr. B. G. Feinberg, Tutor in Chemistry, has been appointed Research Chemist in the Ordnance Division of the United States Army, and ordered to report for duty May 17. Mr. D. L. Williams, Instructor in Chemistry, has been called into the National Service to be in charge of the Division of Supplies of the Research Department of the Gas Warfare Section of the United States Army, to report by June 1 at the latest. Mr. Paul Gross, Tutor in Chemistry, has been commissioned as Second Lieutenant in the United States Army, and was required to report for duty in Washington on the morning of May 9.

Mr. H. Kenyon Burch, who has been connected with the Inspiration and Miami Companies at their Arizona concentrators for several years, has been engaged by the Phelps-Dodge Corporation to design and build the 3000-ton concentrator at Bisbee, Arizona, for the Copper Queen Department.

John A. Traylor has resigned from the position of Western Manager of the Traylor Engineering and Manufacturing Company, and will devote his time to his mining interests, with headquarters in Salt Lake City.

Orville R. Whitaker, who conducted the recent investigation into the smelter schedules in force in Colorado, has been appointed by the Dominion government to be an independent judge on a commission to investigate the new schedules of the Consolidated Mining and Smelting Company of Canada, operating the Trail smelter. The appointment of this commission followed representations from the mining men of British Columbia that the new rates would mean wholesale closing of mines in their province.

Current Market Reports

Non-Ferrous Metal Market

Thursday, May 23—A hearing has been called for at San Francisco by the U. S. Tariff Commission to be held during the week of June 24 to deal with tungsten, quicksilver, antimony and their manufactures.

Antimony.—This metal was in better demand and business of considerable magnitude was done. We quote spot at 12¼@12½c. for the week, with 12½c. at the close.

Chrome.—The Western sellers of this ore have slightly reduced their price and are now more in line with the Eastern market. The latest offers from the West are at $1.50 to $1.55 for 45 per cent Cr_2O_3 f.o.b. shipping point.

Copper.—Prime Lake, Electrolytic and Casting are quoted at $23.50, Government price.

Lead.—There has been no change in the lead market during the last week. The price of 7c New York is maintained; outsiders are quoting slightly above that figure.

Manganese.—Unchanged at $1.20@1.30 per unit for metallurgical ore, 48 per cent grade.

Molybdenum.—Unchanged at $1.15 per pound for 90 per cent grade.

Spelter.—Prices on spelter are quoted at 7¼c. to 7½c. per pound, New York delivery. The Government has fixed the following maximum prices for zinc, subject to the trade discounts and differentials in effect Feb. 13, 1918: Grade A, 12c.; plate, f.o.b. plant, 14c.; sheet, f.o.b. plant, 15c.

Tin.—In view of the clearer position as to shipments of Banca tin to this country the tin market has eased off a little and the London price has now been reduced to £363 per ton. The spot market is exceedingly firm and prices well in excess of $1.00 have been paid for early deliveries.

Tungsten.—Unchanged at $24.00 for scheelite. Tungsten ore of an inferior grade, though available only in small quantities, changed hands at prices according to quality from $20.00 to $23.00.

OTHER METALS

Aluminum, lb., 98-99 per cent., virgin, Government price	32
Bismuth, lb	2 50 3 50
Cadmium, lb	1 40 1 50
Nickel, electrolytic, lb	40
Silver, oz. (official)	99
Platinum, oz	105 00
Palladium, oz	135 00
Cobalt, lb	2 50–3 50
Magnesium, lb	2 00
Quicksilver, Cal	125 00
Quicksilver, Mexican	118 00

The Iron and Steel Market

May has easily been the steel industry's banner month in production, production of ingots having been at the rate of about 45,000,000 tons a year. The best record previously was a rate of 44,400,000 tons, last November. Production in January was at a rate below 30,000,000 tons. Production of finished rolled steel is approximately 75 per cent of the production of ingots. Prior to the war the proportion scarcely varied by one per cent, from 76 per cent, taking a year as a whole, but 1916, with its large production of shell steel, involving heavy discards, brought the proportion down to 75 per cent.

While the steel industry usually sees its heaviest production in March and October, the high point was reached later this year, as the railroads were still in poor operating condition in March.

Pig Iron and Scrap

There is a curious coincidence in the matter of relative production of pig iron and steel ingots. In 1916, the last year for which complete data are available, the production of pig iron was 39,400,000 tons and the production of ingots 41,400,000 tons, showing 2,000,000 tons more ingots than pig iron. A considerable part of the pig iron produced was used in foundries, while on the other hand the steel-making departments used a great deal of scrap, the one tending to balance the other. While there is a wide divergence between the production of steel ingots and the production of finished rolled steel, for many years the production of finished rolled steel has been almost precisely equal to the production of steel-making pig iron, the use of scrap arising outside the steel works approximately making up the carbon and silicon losses from the weight of pig iron as well as the scale produced and other material lost beyond recovery by the open-hearth steel furnace.

Now in April of this year the production of pig iron was at the rate of about $40,400,000 tons and the production of steel ingots at the rate of about 42,650,000 tons, showing approximately the same divergence as was shown in 1916. The coincidence is fortuitous, however. Undoubtedly much less pig iron is being consumed in foundries this year than was the case in 1916, and it follows that the consumption of scrap has been correspondingly less. This is a reflection of the known market condition that scrap is scarce. There is very little old material being brought out, because there is little wrecking of railroad rolling stock and of old bridges and buildings. It is true that there is much shell steel being produced, but that is a condition that obtained in 1916 also, and presumably of late all the scrap possibly applicable to the rolling of commercial steel have been so used. The steel has been rolled into light rails, concrete reinforcing bars, bedstead angles and similar forms, being particularly in request on account of the light supply of old rails for rerolling.

With the insistence of the Government upon a maximum diversion of steel to war purposes it is probable that the employment of shell discard steel in these directions will decrease, the material being forced into the open-hearth furnaces even though from the pecuniary standpoint it is more valuable when rolled into merchantable product. Profits cannot be considered in this connection. Were there not this expectation it is doubtful whether the steel-making units could hope to operate at capacity, for the steel ingot capacity in existence is fully 47,000,000 tons, and it may be a couple million tons more, while the blast furnace capacity can hardly be much in excess of 43,000,000 tons.

War Steel

Since early in April, when the Washington authorities began insisting that the steel industry divert every ton of steel to war work that could possibly be used in filling war orders, there has been an increasing diverting of steel in that direction, and a diminution in shipments to ordinary commercial industries, even though the total production has been increasing steadily.

The great question has been how much steel the war items could possibly use. The insistence upon maximum shipments is no criterion, for the reason that as a measure of safety it is desired that the various war activities be stocked up, and an eye is also held on next winter, when there may be a partial recurrence of the distressing blockade of last winter. Shipbuilding, for instance, may be consuming at the present time less than 200,000 tons of steel a month, but a million tons could easily be accumulated to advantage at the scores of fabricating shops that are serving the shipyards making fabricated ships, and at the shipyards with their hundreds of shipways.

For a clearer insight into this matter, and for a more efficient distribution of the steel as produced, there was appointed on May 17 a joint committee of representatives of the Government and of the steel makers, to go into this whole subject. The committee will gather additional information, and will besides view the matter from a somewhat new angle, the question of time as well as tonnage being considered. Hitherto the orders and requirements of the Government have been stated precisely in terms of tons, but quite indefinitely in terms of delivery periods.

In the past few weeks the matter of steel for shipbuilding has been one of shipping the maximum tonnage possible, irrespective of the rate of current consumption. The steel industry has been expecting that sooner or later the shipbuilding industry would become so stocked that a curtailment would be called in the rate of shipping. Whether this will be the case or not, the announcement in the past fortnight of the shipbuilding program for 1919 gives a more specific suggestion as to the prospects as to the rate of consumption than has hitherto been available. The program involves 3,000,000 tons deadweight of wooden vessels, requiring but a modicum of steel, and 12,000,000 tons deadweight of steel vessels, requiring about one gross ton of finished rolled steel for three tons deadweight vessel capacity. Thus, apparently, the contemplated rate, when shipyards are all working, will involve some 350,000 gross tons a month of rolled steel, which may be compared with about 2,800,000 tons a month production at the latest rate. Very nearly all the capacity available for rolling heavy sheared plates will be engaged, but the contribution of other departments will be light. Shell steel requirements may run 200,000 to 400,000 tons a month. The 100,000 freight cars recently ordered will require fully 1,000,000 gross tons of rolled steel, axles and wheels. Fabricated steel requirements will be heavy for months but this demand will hardly continue. For various requirements large tonnages of sheets and other material are called for. In the long run, however, it seems altogether improbable that all direct war activities will consume much more than half the steel produced.

It has become clearer and clearer, however, that there are scarcely any really nonessential industries, normally consuming steel. Nearly all are more or less helpful, indirectly, towards winning the war. Accordingly, the so-called "commercial" steel is to be distributed according to the relative importance of commercial industries. Already steel for oil production and transport and for agricultural pursuits is being given first preference after war and railroad orders.

A very large tonnage of steel is to be sent abroad. General Pershing has made quite a reputation as a borrower, having borrowed from France and Britain steel in various forms which he has called upon the Government to repay, in the sum of about 1,250,000 tons of steel. There is no longer a measure of the steel that leaves the country, as in the familiar statistics of exports there does not appear the cargoes of vessels owned or chartered by the Government. They do not clear in the usual manner, and the steel they carry, no matter who is the consignee, does not appear as exports.

Chemical Market

Coal Tar Products. The demand for crudes has eased off greatly with considerable change made in prices because of the offerings at price concessions. The intermediates continue to be in good demand, with prices generally unchanged, although inclined to be firmer.

Benzol: Prices have undergone changes because of the surplus offerings which have weakened the tone of the market. Consumers are apparently not interested at present and are awaiting further market changes.

Phenol: The demand continues light with much larger supplies of material coming on the market, as producers who have been giving over their entire output to the government are now offering in the open market. Prices have registered declines.

Toluol: There have been releases made to benzoate of soda producers at varying prices. There is a better prospect in view for the spot market as offerings may become more plentiful should the government permit the release of any quantities of surplus toluol.

Naphthalene: The situation continues to be quiet with considerable ease. Offers have been very liberally made and in order to move material price concessions have been made.

Benzoate of Soda: In the face of offerings of larger quantities of material and the releases being made to producers under government sanction the market has eased up. Prices are lower with a restricted demand.

Dimethylaniline: Production continues to be confined to a few producers. Prices are holding firm with a fairly active demand.

Paranitraniline: There are only few sources of production, although the requirements of the market are being met with. Prices are firm and seem to be inclined higher.

Aniline Oil: Business of moderate proportions is passing Prices are slightly easier.

Beta Naphthol: The demand has lightened, although still of fair proportions. There is little change in the sublimed grade, the price of which is quotably unchanged. The technical grade is the more active.

Alpha Naphthylamine: An easier tone is to be noted and prices have gone a little lower. Supplies that are fairly large are available.

Metatolumylenediamine: The demand is active but not heavy. Production has been helped by the releases of toluol.

Para Amido Phenol: Production of ample proportions is being maintained with prices unchanged.

Phthalic Anhydride: The tone shows no change and is firm. Prices are holding at the same levels.

Heavy Chemicals: Not a great deal of important change is noted one way or the other on any of the items that fall under this classification, and for the most part the condition has been comparatively slow, with prices ruling at slightly lower levels than were previously noted for some items. After several days of inactivity, caustic soda was reported slightly improved late at the close, but its neighbor, soda ash, has failed to respond in sympathy, and wide price ranges continue to be heard on account of considerable speculation as to futures. All acids continue in scant supply in the open market.

Caustic Soda: Business in the New York market on this item has been chiefly of a routine character, but factors reported a slight improvement late at the close in view of

a better inquiry from the majority of large consumers. On spot prices ranged from $4.25 to $4.50, but perhaps on firm bids even these figures could be shaded because there are apparently sufficient supplies on hand to take care of a better consumer demand. Not a great deal of additional interest is being displayed on forward positions and prices are quotably unchanged on contracts for over the year in the neighborhood of 4.60 works. For 1919 business from 3¼c. works is the figures most generally heard for the 60 per cent, but little business is noted for this position.

Soda Ash: This item continues to be neglected by the majority of users, and prices continue at lower levels than have been named for a long time. For stocks in bags prices for spot were practically at unchanged levels of a week ago of 2.15 store. Ash in barrels is of little interest at this writing to consumers and closing figures were at 2.60 and up to 2.70, according to quantity. Little underlying strength is noted on account of comparatively light inquiries.

Acetic Acid: For the most part all acetic acid is nominal on account of large requirements from the Government for this material. Little, therefore, is reaching the open market and sales that have been recorded have passed at higher levels than have been noted for some time. The demand is heavy from all directions and the principal accomplishment in practically any degree of this product is that of locating supplies. During the interval sales have been recorded on the 28 per cent material as high as 16¼c., barrels inclusive, and 35c. for the 56 per cent material, barrels extra. Not in a long time has there been such a tight condition as is now noted on acetic acid.

Sulphuric Acid: All sulphuric acid reported as unchanged from the condition that prevailed in this market a week ago. Very few offers of the 60-degree material are noted, and as a rule the buyer continues to prefer 66-degree material when same is available at a favorable figure. In some quarters it is stated that prices for stocks on spot of the 66-degree brimstone acid have advanced, but in second hands sales have been noted as low as $32.50 per ton in sellers' tanks works. Some of the large producers, however, continue to ask as high as $34.00 a ton sellers' tanks works for the ordinary run of business.

Oleum: For tank cars possibly $55.00 is workable. Some business in 60 per cent oleum at $225.00 per ton, and up, but it appears that the production has now been disposed of, and few new orders have been heard at this figure. The situation apparently continues to improve and large offerings are less frequently heard, but in view of a decidedly unsettled condition comparatively wide price ranges continue to be heard.

Yellow Prussiate of Soda: The production of this material continues to be confined to a few firms and is seemingly not sufficiently large to take care of all the business that is now being placed. Prices for spot and nearby stocks are decidedly higher at the close and in a number of important quarters as high as 75c. a pound. The inside quotation heard for this material has been at 70c. With additional inquiries there is more underlying strength than has been noted in this market for some time.

Yellow Prussiate of Potash: Domestic stocks are available at $1.20, and up to $1.25, according to quantity. Offerings are not large and supplies, it is reported, are barely sufficient to take care of all the business that is now being placed. The Japanese materials are nominal, since importers are unable to get ample stocks from the Orient to take care of the volume of business noted.

Cyanide of Soda: Business has been confined chiefly to second hands during the interval, and 38c. has been the figure most generally heard from this quarter. The ordinary seller, however, continues to quote firmly at 40c. and up.

Copper Sulphate: The market has been barely steady on this product, and apparently at the close 9¼c. a pound could have been shaded on a firm bid. The inquiry is active, but no large orders have been recorded and the undertone of the market is not particularly strong.

Bichromate of Soda: It is difficult to get a correct line on the prevailing conditions in the New York market on bichromate of soda. Wide price ranges are heard because of an unsettled condition and closing figures were 24¼c. as the inside, and up to 25c. a pound as the maximum. Additional inquiry interest is being manifested daily on this material.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, MAY 24, 1918

Acetic anhydride	lb.	1 50 —	1 60
Acetone, drums	lb.	Nominal	
Acid, acetic, 28 per cent	lb.	Nominal	
Acetic, 56 per cent	lb.	Nominal	
Acetic, glacial, 99½ per cent., carboys	lb.	Nominal	
Boric, crystals	lb.	13½ —	14½
Citric, crystals	lb.	87 —	88
Hydrochloric, C. P.	lb.	Nominal	
Hydrochloric, 20 deg.	lb.	02½ —	02½
Hydrochloric, conc., 22 deg.	lb.	02½ —	03
Hydrofluoric, 30 per cent., in barrels	lb.	06 —	06½
Lactic, 44 per cent	lb.	11 —	12
Lactic, 22 per cent	lb.	06 —	06½
Molybdic, 85 per cent	lb.	3 85 —	
Nitric, 36 deg.	lb.	08½ —	08½
Nitric, 42 deg.	lb.	09 —	10
Oxalic, crystals	lb.	42 —	43
Phosphoric, 42–50 per cent. paste	lb.	08 —	10
Phosphoric, ref. 50 per cent	lb.	26 —	
Picric	lb.	Nominal	
Pyrogallic, resublimed	lb.	3 10 —	3 15
Sulphuric, 60 deg.	ton	25 00 —	27 50
Sulphuric, 66 deg.	ton	32 50 —	35 00
Sulphuric, oleum (Fuming), tank cars	ton	55 00 —	60 00
Tannic, U. S. P., bulk	lb.	1 30 —	1 35
Tartaric, crystals	lb.	86 —	87
Tungstic, per lb. of W	lb.	1 70 —	1 75
Alcohol, sugar cane, 188 proof	gal.	4 93 —	4 95
Alcol, wood, 95 per cent	gal.	90½ —	91
Alcohol, denatured, 180 proof	gal.	68 —	69
Alum, ammonia lump	lb.	04 —	04½
Alum, chrome ammonium	lb.	18 —	19
Alum, chrome potassium	lb.	20 —	21
Alum, chrome sodium	lb.	12½ —	13
Alum, potash lump	lb.	08½ —	09
Aluminium sulphate, technical	lb.	02½ —	03
Aluminium sulphate, iron free	lb.	03½ —	03½
Ammonia aqua, 26 deg. carboys	lb.	26 —	27
Ammonia, anhydrous	lb.	Nominal	
Ammonium carbonate	lb.	Nominal	
Ammonium nitrate	lb.	(Fixed price)	15
Ammonium, sulphate domestic	lb.	07½ —	08
Amyl acetate	gal.	5 00 —	5 25
Arsenic, white	lb.	09 —	12
Arsenic, red	lb.	35 —	40
Barium carbonate, 99 per cent.	ton	80 00 —	90 00
Barium carbonate, 97–98 per cent	ton	65 00 —	67 00
Barium chloride	ton	65 00 —	85 00
Barium sulphate (Blanc Fixe, Dry)	lb.	02½ —	02½
Barium nitrate	lb.	09½ —	10
Barium peroxide, basis 70 per cent	lb.	30 —	32
Bleaching powder, 35 per cent. chlorine	lb.	01 —	02
Borax, crystals, sacks	lb.	07½ —	08½
Brimstone, crude	ton	Nominal	
Bromine, technical	lb.	75 —	
Calcium, acetate, crude	lb.	Nominal	
Calcium, carbide	lb.	12½ —	14½
Calcium chloride, 70-75 per cent., fused, lump	ton	27 50 —	30 00
Calcium peroxide	lb.	1 60 —	1 70
Calcium phosphate	lb.	34 —	35
Calcium sulphate 98-99 per cent	lb.	09 —	09½
Carbon bisulphide	lb.	08½ —	10
Carbon tetrachloride, drums	lb.	15½ —	16
Carbonyl chloride (phosgene)	lb.	1 10 —	1 50
Caustic potash, 88–92 per cent	lb.	83½ —	84
Caustic soda, 76 per cent	lb.	04½ —	04½
Chlorine, liquid	lb.	15 —	18
Cobalt oxide	lb.	1 60 —	1 65
Copperas	lb.	01½ —	01½
Copper carbonate	lb.	30 —	40
Copper cyanide	lb.	75 —	78
Copper sulphate, 99 per cent., large crystals	lb.	08½ —	09
Cream of tartar, crystals	lb.	80 —	82
Epsom salt, bags, U.S.P.	lb.	03½ —	03½
Formaldehyde, 40 per cent	lb.	18½ —	19
Glauber's salt	100 lb.	1 50 —	1 75
Glycerine, bulk, C. P.	lb.	63½ —	64
Iodine, resublimed	lb.	4 25 —	4 30
Iron oxide	lb.	13 —	15
Lead, acetate, white crystals	lb.	17 —	18
Lead, arsenate (Paste)	lb.	15 —	18
Lead nitrate	lb.	15 —	16
Litharge, American	lb.	09½ —	11½
Lithium carbonate	lb.	1 50 —	2 00
Manganese dioxide, U. S. P.	lb.	70 —	75
Magnesium carbonate, technical	lb.	10½ —	11
Nickel salt, single	lb.	14 —	15
Nickel salt, double	lb.	12 —	14
Phosgene, see Carbonyl chloride			
Phosphorus, red	lb.	1 30 —	1 50
Phosphorus, yellow	lb.	1 50 —	1 60
Potassium bichromate	lb.	44 —	46
Potassium bromide granular	lb.	1 35 —	1 50
Potassium carbonate calcined, 85-90 per cent	lb.	40 —	50
Potassium chlorate, crystals	lb.	38 —	40
Potassium cyanide, 98-99 per cent	lb.	Nominal	
Potassium iodide	lb.	3 25 —	3 80
Potassium muriate 80-85 per cent. basis of 80 per cent	ton	325 00 —	350 00
Potassium nitrate	lb.	22 —	31
Potassium permanganate U. S. P.	lb.	3 65 —	3 75
Potassium prussiate, red	lb.	2 80 —	2 90
Potassium prussiate, yellow	lb.	1 15 —	1 20
Potassium sulphate, 90–95 p. c. basis 90 p. c.	ton	Nominal	
Rochelle salts	lb.	43 —	44
Salammoniac, gray gran.	lb.	18 —	19
Salammoniac, white gran.	lb.	17½ —	18
Sal soda	100 lb.	1 35 —	1 40
Salt cake	ton	22 50 —	25 00
Silver cyanide, based on market price of silver	oz.	61½ —	62
Silver nitrate	oz.	2 10 —	2 20
Soda ash, 58 per cent., light, flat (bags)	100 lb.		

Soda ash, 58 per cent., dense, flat	100 lb.	3.75	—	3.85
Sodium acetate	lb.	.23	—	.24
Sodium bicarbonate, domestic	lb.	.02½	—	.03
Sodium bicarbonate, English	lb.			
Sodium bichromate	lb.	.23½	—	.24½
Sodium bisulphite, powd.	lb.	.05¾	—	.06
Sodium chlorate	lb.	.24	—	.25
Sodium cyanide	lb.	.38	—	.40
Sodium fluoride, commercial	lb.	.18	—	.19
Sodium hyposulphite	lb.	.02½	—	.02¾
Sodium molybdate, per lb. of Mo	lb.	2.50	—	
Sodium nitrate, 95 per cent	100 lb.	Nominal		
Sodium nitrite	lb.	.29	—	.32
Sodium peroxide	lb.	.48	—	.50
Sodium phosphate	lb.	.04	—	.05
Sodium prussiate, yellow	lb.	.68	—	.69
Sodium silicate, liquid (60 deg.)	lb.	Nominal		
Sodium sulphide, 30 per cent., crystals	lb.	.02½	—	.03
Sodium sulphide, 60 per cent., fused	lb.	.05¾	—	.06
Sodium sulphite	lb.	Nominal		
Strontium nitrate	lb.	.25	—	.35
Sulphur chloride, drums	lb.	.06	—	.06½
Sulphur dioxide, liquid, in cylinders	lb.	.15	—	.40
Sulphur, flowers, sublimed	100 lb.	4.05	—	4.60
Sulphur, roll	100 lb.	3.70	—	3.85
Sulphur, crude	ton	Nominal		
Tin bichloride, 50 deg	lb.	.23½	—	.24½
Tin oxide	lb.	.78	—	.80
Zinc carbonate	lb.	.25	—	.30
Zinc chloride	lb.	.12½	—	.13
Zinc cyanide	lb.	Nominal		
Zinc dust, 350 mesh	lb.	.14	—	.16
Zinc oxide, American process XX	lb.	.12½	—	.14
Zinc sulphate	lb.	.05	—	.06

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.27	—	.30
Benzol, 90 per cent	gal.			
Toluol, in tank cars	gal.	(Fixed Price)		1.50
Toluol, for non-military use, in drums	gal.	(Fixed Price)		1.55
Xylol, pure, water white	gal.	.35	—	.50
Solvent naphtha, water white	gal.	.17	—	.22
Solvent naphtha, crude, heavy	gal.	.13	—	.16
Creosote oil, 25 per cent	gal.	.33	—	.35
Dip oil, 20 per cent	gal.	.29	—	.30
Pitch, various grades	ton	8.00	—	20.00
Carbolic acid, crude, 95-97 per cent	lb.	1.05	—	1.10
Carbolic acid, crude, 50 per cent	lb.	.60	—	.65
Carbolic acid, crude, 25 per cent	lb.	.35	—	.38
Cresol, U. S. P.	lb.	.18	—	.20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.00	—	1.25
Alpha naphthol, distilled	lb.	1.60	—	2.00
Alpha naphthylamine	lb.	.58	—	.60
Aniline oil, drums extra	lb.	.25½	—	.27
Aniline salts	lb.	.32	—	.34
Anthracene, 80 per cent	lb.	.50	—	.65
Benzaldehyde (f.l.c.)	lb.	5.50	—	6.00
Benzidine, base	lb.	1.75	—	1.85
Benzidine, sulphate	lb.	1.40	—	1.50
Benzoic acid U. S. P.	lb.	3.75	—	3.90
Benzoate of Soda, U. S. P.	lb.	3.30	—	3.40
Benzyl chloride	lb.	2.25	—	2.75
Beta naphthol benzoate	lb.	10.00	—	12.00
Beta naphthol, sublimed	lb.	.85	—	.90
Beta naphthylamine, sublimed	lb.	2.65	—	
Dichlor benzol	lb.	.12	—	.18
Diethylaniline	lb.	4.50	—	5.00
Dinitro benzol	lb.	.35	—	.40
Dinitrochlorbenzol	lb.	.40	—	.42
Dinitronaphthaline	lb.	.55	—	.60
Dinitrotoluol	lb.	.55	—	.60
Dinitropbenol	lb.	.46	—	.50
Dimethylaniline	lb.	.70	—	.72
Diphenylamine	lb.	1.00	—	1.10
H-acid	lb.	2.25	—	2.50
Metaphenylenediamine	lb.	2.00	—	2.25
Monochlorbenzol	lb.	.17	—	.19
Naphthalene, flake	lb.	.09½	—	.09¾
Naphthalene, balls	lb.	.10¾	—	.10¾
Naphthionic acid, crude	lb.	1.20	—	1.30
Naphthylamin-di-sulphonic acid	lb.	1.00	—	1.10
Nitro naphthaline	lb.	.45	—	.50
Nitro toluol	lb.	.50	—	.55
Ortho-amidophenol	lb.			
Ortho-dichlor-benzol	lb.	.15	—	.18
Ortho-toluidine	lb.	1.00	—	1.25
Ortho-nitro-toluol	lb.	.75	—	1.00
Para-amidopbenol, base	lb.	3.50	—	3.75
Para-amido-phenol, H. Ch.	lb.	4.00	—	5.00
Para-dichlor-benzol	lb.	.12	—	.15
Paranitraniline	lb.	1.50	—	1.55
Para-nitro-toluol	lb.	1.50	—	1.60
Paraphenylenediamine (base)	lb.	3.00	—	3.25
Para toluidine	lb.	2.25	—	2.50
Phthalic acid anhydride	lb.	3.50	—	4.00
Phenol, U. S. P.	lb.	.48	—	.49
Resorcin, technical	lb.	5.75	—	6.00
Resorcin, pure	lb.	8.50	—	9.00
Salicylic acid	lb.	.88	—	.90
Salol	lb.	1.90	—	2.00
Sulphanilic acid, crude	lb.	.30	—	.32
Tolidin	lb.	2.50	—	
Toluidine-mixture	lb.	.75	—	.85

INDUSTRIAL NEWS

Plant Construction—Catalogs—New Publications

Construction and Operation

Arizona

TUCSON.—The Pima Mining & Smelting Co. plans to enlarge the capacity of its smelter plant from 250 tons to 500 tons daily. William Kemp is manager.

California

GRASS VALLEY.—The Grass Valley Consolidated Gold Mines Co. is building a shaft, mill and cyanide plant. Estimated cost, $225,000.

OATMAN.—The Mossback Mines, at Line Road section of Gold Road property, plans to install a new crushing plant. About half a dozen buildings will be put up, powerful plant installed and main shaft sunk from present depth of 300 ft. to 500 or 600 ft.

Connecticut

BRIDGEPORT.—Whipple & Choate Co., Iranistan Ave., has awarded the contract for the construction of a 1-story, 27 x 27 ft., mill construction addition to its foundry, to H. D. Moon, 208 Stratford Rd. and T. O'Brien, 137 Black Road Ave.

HARTFORD.—The Hartford Rubber Co., Park St., has awarded the contract for the construction of a 1½-story, 50 x 150 ft., concrete, brick and steel factory on Bartholomew Ave., to S. H. Grozier Co., 721 Main St. Estimated cost, $14,000.

HARTFORD.—The Maxim Silencer Co., 81 Homestead Ave., has awarded the contract for the construction of a 1½-story, 30 x 300 ft. factory to be used for the manufacture of attachments for guns, to the Ellison Construction Co., 60 Prospect St. Estimated cost, $20,000.

WATERBURY.—The Waterbury Clock Co., 31 Cherry Ave., plans to build a large manufacturing building.

Idaho

WALLACE.—The Friend Mining Co., will install a mill consisting of crusher, ball mill, flotation machine and concentrating table.

Illinois

CHICAGO.—The Cross Press & Sign Co., c/o C. E. Frazier, 30 North Dearborn St., plans to build a 1- and 2-story, 75 x 75 ft., reinforced concrete tannery at Dayton and Black Hawk Sts. Estimated cost, $15,000.

CHICAGO.—B. Heller & Co., 3925 Calumet Ave., manufacturer of edible chemicals, plans to build a 2-story, 125 x 250 ft. brick addition to factory. J. C. Llewellyn, 38 South Dearborn St., is engineer.

CHICAGO.—The International Harvester Corporation, Chicago, has awarded the contract for the construction of a grey iron foundry, to McClintic Marshall Co., 38 South Dearborn St.

CHICAGO.—The Western Dry Color Co., 608 West 52nd St., will build a 2-story brick factory. Estimated cost, $5000.

CICERO.—The General Malleable Co., South 55th Court and West 14th St., will build a 1-story, 132 x 222 ft. brick factory and warehouse at South 55th Court and West 13th St. Estimated cost, $18,000.

GRANITE CITY.—The Commonwealth Steel Co., Pierce Building, St. Louis, Mo., will build a 1- and 2-story addition to its plant. Estimated cost, $500,000.

KANKAKEE.—The American Truck & Aeroplane Co. has purchased the plant of the Unifle Co. at Riverview Ill. and will equip same for the manufacture of automobile motor trucks and airplanes.

Indiana

ANDERSON.—The Hill Pump Co. has awarded the contract for the construction of a 100 x 200 ft., brick and steel foundry at the south end of its plant, to the Builders Construction Co., Indianapolis. Estimated cost, $45,000.

GARY.—The Illinois Steel Co., 208 South La Salle St., Chicago, Ill., has awarded the contract for the construction of two 141,000 gallon sulphuric acid tanks at its plant here to the American Bridge Co., 208 South La Salle St., Chicago.

GARY POST.—The Gary Motor Truck Co., 610 Broadway plans to build a large addition to its plant.

SOUTH BEND.—The Malleable Steel Range Co., Cherry St. and Jefferson Blvd., plans to build a 2-story 34 x 88 ft. brick and steel factory building. Estimated cost, $10,000.

TERRE HAUTE.—An addition will be built to the machine shop at the Gott Glass Co. Johnson & Miller, 105 South Seventh St. is the architect.

WABASH.—The Service Motor Truck Co. will build a 1-story, 75 x 200 and 75 x 150 ft. factory. Nicol & Dietz, 212 Murdock Building, La Fayette, architects.

DES MOINES.—The Green Foundry & Furnace Works, 100-10 South West 2nd St., plans to build a 106 x 110 ft. brick and steel foundry. Frank D. Chase, Inc., 122 South Michigan Ave., Chicago, Ill. is engineer.

Iowa

FORT MADISON.—The Karamoid Manufacturing Co. will build a 2-story, 60 x 200 ft., brick, pulp container factory here by day labor. F. J. Klein, 127 South Jefferson St., architect, will supervise construction.

SIOUX CITY.—The Sioux City Tire & Manufacturing Co. plans to construct several new additions to its plant.

STORM LAKE.—The International Chemical Co. will build a factory at Lakeside Farm, a mile from the city, for the manufacture of phenol to be used by the Government in the manufacture of explosives.

Kansas

BAXTER SPRINGS.—C. M. Mitchell, E. D. Nix and L. H. Knight will build 75 ton concentrating mill at mine here to include crushers, slime tables, engines and boilers. Estimated cost, $50,000.

Massachusetts

CAMBRIDGE.—Harvard University will build a biophysical laboratory on Huntington Ave. Estimated cost $60,000. Coolidge & Shattuck, Ames Building, Boston, architects.

NORTHAMPTON.—The Trustees of Smith College, College Hall, have awarded the contract for the construction of a brick addition to the chemistry building, to Allen Bros., 125 South Pleasant St., Amherst.

WORCESTER.—The Worcester Stamped Metal Co., 9 Hunt St., has awarded the contract for the construction of a 1-story brick addition to its plant, to E. J. Cross Co., 82 Foster St. Estimated cost $10,000.

Michigan

DETROIT.—The Ford Motor Co. Highland Park will build an addition to its plant consisting of 16 shops, 18 x 260 ft. The new plant will be used for the assembly and testing of the Liberty Motor.

DETROIT.—The McCord Manufacturing Co., Grand Boulevard and Orleans St., has awarded the contract for the construction of a 1- and 3-story 161 x 372 ft. reinforced concrete munition factory to Pleas Construction Co., 30 North La Salle St., Chicago, Ill. Estimated cost $70,000.

Minnesota

ST. PAUL.—The American Hoist & Derrick Co., Water and Roberts Sts., has awarded the contract for the construction of a 1-story 20 x 40 x 74 ft. brick and steel machine shop, to G. J. Grant Construction Co., Exchange Bank Building. Estimated cost $19,270.

Missouri

PLEASANT HILL.—City let contract for sewage disposal plant to Lange & McDonald Construction Co., Moberly.

SENECA.—The Oklahoma Motor Co. plans to install stone tables, rock crusher, engines and boilers in its mine here. Estimated cost $75,000. C. T. Jobes, is architect in charge.

ST. JOSEPH.—The Berry Iron & Steel Co., 5th and Oak Sts. has awarded the contract for the construction of a new [illegible] to replace the one destroyed by fire. The Lehr Construction Co., 1712 Fred Ave., will erect five buildings for storage, and one for the office of concrete, brick and steel construction.

WEST PLAINS.—The Missouri Iron & Steel Corporation plans to build a smelting plant here. The construction of the company's ore in Howell County has yet to be extended [illegible] operations in North Arkansas and South Missouri. Estimated cost $6,000,000.

Montana

POLARIS.—The Silver Figure Mining Co. will build a mill roasting and hydrosulphide plant here.

Nebraska

PLATTSMOUTH.—The Auto Power & Malleable Co. has taken over the plant and business of the Western Machine Foundry Co. and will build a new and larger plant. Estimated cost, $250,000.

New Jersey

HOBOKEN.—W. & A. Fletcher Co., 1204 Hudson St., has awarded the contract for the construction of a 3-story, 50 x 145 ft. brick factory for the manufacture of marine engines, etc., to William Crawford, 7 East 42nd St., New York City. Estimated cost, $50,000.

HOBOKEN.—The Remington Arms Co.-Union Metallic Cartridge Co., 1540 Hudson St., has awarded the contract for the construction of a 1-story, 81 x 160 ft., reinforced concrete, brick and steel factory to Austin Co., 16112 Euclid Ave., Cleveland, O. Estimated cost $100,000.

JERSEY CITY.—The Vulcan Iron Works, Morris St., plans to build two 1-story, 60 x 100 ft., brick and steel additions to its plant on Hudson St. Estimated cost, $50,000.

MILLVILLE.—The International Glass Co. has awarded the contract for the construction of a 1-story, 60 x 104 ft., concrete, brick and steel glass factory here to Austin Co., 16112 Euclid Ave., Cleveland, O. Estimated cost, $35,000.

NEWARK.—C. A. Goldsmith, Ave. D and Thomas St., will build a 1-story, 50 x 150 ft., brick brass foundry. Estimated cost, $24,000.

NEWARK.—The Holophane Glass Co., east side of Oakwood Ave. near the Pennsylvania Railroad tracks, will build a 50 x 75 ft. tank shop. Capacity two and one-half tons of molten glass.

TRENTON.—The Trenton Malleable Iron Co., New York Ave., has awarded the contract for the construction of a 1-story, 44 x 146 ft., concrete, brick and steel foundry addition, to N. A. Bugbee Co., 241 West State St. Estimated cost $10,000.

New York

BUFFALO.—The Acme Steel & Malleable Iron Works, 120 Chandler St., has awarded the contract for the construction of a 1-story, 100 x 175 ft. brick and steel iron plant, to J. W. Cowpers Co., Fidelity Building. Estimated cost $25,000.

BUFFALO.—The Ferguson Steel & Iron Co., 1399 Valley Ave., has awarded the contract for the construction of a 1-story, 400 x 800 ft., concrete, brick and steel shipbuilding plant to J. W. Cowpers Co., Fidelity Building. Estimated cost $100,000.

BROOKLYN.—The Decorated Metal Co., 196 Degraw St., has awarded the contract for altering the tenement at 192 Degraw St. into a factory for its own use, also building 1-story addition to H. D. Best Co., 52 Vanderbilt Ave., New York City. Estimated cost, $20,000.

BROOKLYN.—The Improved Appliance Co., manufacturer of gas appliances, 455 Kent Ave., plans to build a 1-story, 67 x 97 ft., reinforced concrete, brick and timber factory. Estimated cost $15,000.

LONG ISLAND CITY.—The John Palcoreck Bronze & Iron Co., 48 Hancock St., will build a 1-story, 75 x 100 ft. concrete and brick foundry. H. Hutton, architect. Estimated cost $15,000.

LONG ISLAND CITY.—The [illegible] Sterling & Packing Co., 35-37 Eider Ave., has awarded the contract for the construction of 11 [illegible] 75 x 150 ft. [illegible] roof, to McGraw Construction Co., 1178 Broadway, New York City. Estimated cost $[illegible].

LONG ISLAND CITY.—The [illegible] Iron & Steel Co., 43 Hancock St., has awarded the contract for a 1-story, 75 x 150 ft. [illegible] foundry. Estimated cost $[illegible].

MASSETH.—The Dexter Steel & Forging Co. will build a 1-story, [illegible] Creek St. 75 ft. [illegible] Estimated cost $[illegible].

NEW YORK.—The Yale [illegible] Co., [illegible] 1-story [illegible] Estimated cost $[illegible].

[illegible] Bros. Co., [illegible] Estimated cost $[illegible].

[illegible] Co., [illegible] Estimated cost $[illegible].

[illegible] Co., [illegible] Estimated cost $[illegible].

[illegible]

ROCHESTER.—The High Speed Hammer Co., Norton St., will build a plant consisting of two buildings, at Clinton Ave., N., and Hellenbeck St., one to be 1-story, 53 x 101 ft. and another 2-story, 18 x 53 ft. Estimated cost, $40,000.

Ohio

CANTON.—The Timken Roller Bearing Co., Dueber Ave., will build a steel manufacturing building. Estimated cost, $180,000. The company recently obtained a large order from the Government for automobile machinery.

CINCINNATI.—The Cincinnati Gear Co., 1825 Reading Road, will build a 1-story, concrete and brick addition to its factory. Estimated cost, $24,000.

CINCINNATI.—The City will build a new asphalt plant on Florence Ave., to replace the one destroyed by fire, entailing a loss of $20,000.

CINCINNATI.—(Norwood) The George B. Curd Co. has purchased the factory on Highland Ave. formerly occupied by the Niebling Ice Machine Co. and will remodel same for its own use as a locomotive repair shop.

CINCINNATI.—The John H. McGowan Co., 52 Central Ave., will remodel, also build an addition, to its machine plant. Estimated cost, $10,000.

CINCINNATI.—The John B. Morris Foundry Co., Court and Harriet Sts., will improve its plant. Estimated cost, $10,000.

CINCINNATI.—(Oakley) The Trailmobile Co. manufacturer of automobile trailers, will build a manufacturing building to contain 80,000 sq ft. floor space. Estimated cost, $300,000. E. M. Chase, Union Centre Building, is engineer.

CLEVELAND.—The Crucible Steel Forge Co., Grant Ave., plans to build a 1-story shop addition. Estimated cost, $30,000.

CLEVELAND.—The Damascus Manufacturing Co., manufacturer of oil specialties, East 93rd and Cassius Sts., has awarded the contract for the construction of a 2-story, 30 x 50 and 80 x 105 ft., concrete, brick and steel factory addition, to J. H. Chaney & Son Co., 563 Hippodrome Annex. Estimated cost, $30,000.

CLEVELAND.—The Templin-Crockett-Bradley Co., 5700 Detroit Ave., has awarded the contract for the construction of an addition to its plant, to F. A. Skeel, 3719 Cypress Ave. Estimated cost, $30,000.

CLEVELAND.—The Wilberite Roofing Co., Brook Park and State Roads, is building a new factory here. Estimated cost, $22,000.

CLEVELAND.—The Willard Storage Battery Co., 274 East 131st St., plans to build a concrete, brick and steel factory and office building. Estimated cost, $150,000.

COLUMBUS.—The Atlas Brass Foundry Co., Stewart Ave. and Park St., S., has awarded the contract for the construction of a new factory addition, to Nonnemacher & Frank, East Gates St. Estimated cost, $8000.

COLUMBUS.—The Columbus Rendering Co., Frank Road and Jackson Pike, has awarded the contract for the construction of a 2-story, 32 x 72 ft. brick rendering plant, to E. Elford, Commercial Building. Estimated cost, $15,000.

DAYTON.—The Advance Foundry Co., Harshman and Crane Sts., plans to build a new grey iron foundry on Parnell Ave., near the Pennsylvania R.R. Estimated cost, $200,000.

EUCLID.—The Euclid Chemical Co., c/o R. L. Beck, 311 The Arcade, Cleveland, will build a 3-story, reinforced concrete, brick and steel factory. Estimated cost, $50,000.

HAMILTON.—The Black & Clawson Co., 2nd and Vine Sts., builder of paper-making machinery, has awarded the contract for the construction of a 1-story, 60 x 80 ft., brick and steel addition to its foundry, to Bert L. Baldwin Co., 502 Second National Bank Building, Cincinnati

LONDON.—The London Fabrics Mill Co., recently incorporated, will build a 60 x 70 ft. brick and steel factory for the manufacture of fabrics to go into rubber tires.

NORWOOD.—The A. V Carroll Machine Tool Co., Highland Ave., has awarded the contract for the construction of a new plant, to F. E. Ratcliff, Batavia. Estimated cost, $10,000.

NORWOOD.—The Warman Aluminum Castings Co., 1741 Central St., Cincinnati, has leased a building at Main and Lexington Aves. and will equip same for the manufacture of aluminium castings.

SANDUSKY.—The Farrell Cheekseel Foundry, foot of 1st St., will build an addition to its plant.

SANDUSKY.—The Vim Motor Co., Water and Meigs Sts., has awarded the contract for the construction of a 100 x 180 ft. addition to its plant, to A. S Schnurr, 1003 West Jefferson St.

TOLEDO.—The Bunting Brass & Bronze Co., Spencer and Carlton Sts., will build a 2-story, 120 x 175 ft., brick, cement and steel brass foundry. Estimated cost, $150,000. Mills, Rhines, Bellman & Nordhoff, 1234 Ohio Building, architects.

TOLEDO.—The Royster Guano Co., 813 Second National Bank Building, will build a fertilizer plant on Stickney Ave. Estimated cost, $35,000.

TOLEDO.—The Toledo Tap & Die Co., Clinton St., plans to build a 1-story, 50 x 200 ft., concrete, brick and steel factory, for the manufacture of machine tools, taps and dies. Estimated cost, $20,000.

WARREN.—The A. B. Smith Chemical Co., Red House, will build a new plant to replace the one destroyed by fire with a loss of $150,000.

Oklahoma

BARTLESVILLE.—The Bureau of Mines plans to build a 2-story, 42 x 102 ft. laboratory of brick construction. Keene & Simpson, 400 Reliance Building, architects. Estimated cost, $30,000.

GUTHRIE.—The Empire Oil & Gas Co. plans to build a second oil refinery here.

MIAMI.—The Lightfoot Oil & Mining Co. will build a 100 ton concentrating mill to include slime tables, crushers, engines, boilers and air machines. Estimated cost, $100,000. H. Holman, is vice president.

MIAMI.—The Mint Mining Co. will build two 75 ton concentrating mills to include slime tables, crushers, boilers and engines. Estimated cost, $100,000. Julius Labsap is superintendent.

Pennsylvania

FORD CITY.—The Fawcus Machine Co. plans to build a 50 x 100 ft. addition to its plant here. The Company recently obtained several large Government orders which make this addition necessary.

MORRISTOWN.—The Conshohocken Iron & Steel Co. plans to build a modern ore crushing mill, for crushing chrome ore, which is used in steel making, furnace lining and other work.

PHILADELPHIA.—The Aetna Foundry Co., 22nd St. and Allegheny Ave., has awarded the contract for the construction of a 1-story, 50 x 70 and 20 x 50 ft., brick foundry, to A. Raymond Raff, 17th and Thompson Sts. Estimated cost, $10,000.

PHILADELPHIA.—The Cresson & Morris Co. has awarded the contract for the construction of a 50 x 100 ft. foundry at 18th St. and Allegheny Ave., to the Raith Construction Co., 302 West Master St.

PHILADELPHIA.—Morris Wheeler & Co. has awarded the contract for the construction of a 467 x 616 x 325 ft. fabricating steel shop, fireproof, to William Steele & Sons, 308 South 15th St. Estimated cost $500,000.

PHILADELPHIA.—The United States Government will build a 1-story, 57 x 154 ft., brick and reinforced concrete, aircraft factory at League Island. Estimated cost, $20,000. W. Deiley, 1616 Thompson St., is architect.

PITTSBURGH.—The C. R. Moore Co., Arrott Tower Building, plans to build a 1-story, concrete, brick and steel printing house on West Liberty Ave., Nineteenth Ward. Estimated cost, $45,000.

Rhode Island

PAWTUCKET.—The Collyer Insulated Wire Co., 249 North Main St., will build a 3 story, 83 x 170 ft. brick manufacturing plant. Estimated cost, $80,000.

Tennessee

LYLES.—The United States Government has awarded the contract for the construction of a wood chemical plant, to George A. Fuller Construction Co., 175 5th Ave., New York City. Estimated cost, $1,300,000. The Bon Air Coal & Iron Corporation, Stahlman Building, Nashville, will operate the plant for the Government.

Texas

WACO.—W. McMahon, 802 Kipling St., plans to build a refinery at the South Bosque oil fields.

Utah

SALT LAKE.—The Lucky Star Copper Co. plans to build a small concentration plant at its mine in the Dugway District.

Virginia

SEVEN PINES.—The War Department, Washington, D. C., has awarded the contract for the construction of a powder packing plant here, to the Foundation Co., Woolworth Building, 233 Broadway, New York City. Estimated cost, $3,000,000. E. I. DuPont de Nemours & Co., Henry Clay St., Wilmington, Del., will operate the plant for the Government.

Washington

EVERETT.—Everett Lister plans to build a plant here for the manufacture of potash from wood ashes and later from kelp.

EVERETT.—The Everett Steel Co. will build a 75 x 100 ft., brick building on McDougall St. between Wall St. and Smith Ave. T. B. Sumner of Sumner Iron Works is president of new company.

SPOKANE.—The Armstead Mines will build a concentrating mill and purchase additional equipment. Estimated cost, $100,000. The first unit of the plant will have about 100 tons capacity.

West Virginia

FAIRMONT.—The Fairmont By-Products Co. will build a by-product coke oven plant. Initial capacity 110 tons ovens and ultimate 330. Estimated cost, $5,000,000.

SUTTON.—The Sutton Chemical Co. will build an addition to its plant here. Estimated cost, $200,000. The company recently obtained large contracts from the Government which makes this addition necessary.

Wisconsin

CARROLLVILLE.—The Newport Chemical Works, manufacturer of phenol products 1112 First National Bank Building, Milwaukee, will build an addition to its plant here.

EAU CLAIRE.—The United States Switch Co. plans to build additions to double the capacity of its foundry and install milling machines, turret lathes and a one-ton electric steel furnace. A complete drop forge unit also will be added.

MILWAUKEE.—The Universal Machinery Co., 784 30th St., manufacturer of lathes and other machine tools, plans to build a new foundry and machine shop at the foot of 64th Ave. Estimated cost, $250,000. Frank E. Gray, 86 Michigan St., is architect.

PLYMOUTH.—The National Milk Sugar Co., 16 Park Row, New York City, will build a 1-story and 2-story, 40 x 120 ft., brick and mill construction sugar refinery here. Estimated cost, $20,000.

WEST ALLIS.—The Universal Machinery Co., 784 30th St., will build a 150 x 250 ft. factory, 100 x 150 ft. foundry, and a 50 x 50 ft. power house. Estimated cost, $250,000. E. C. Devine is president.

Canada

ILLICILLEWAET, B. C.—The Lanark Mines Co. is installing hydro electric plant at its mine here. Estimated cost, $300,000.

Industrial News

The CLARAGE FAN COMPANY, Kalamazoo, Mich., announces the removal of their Chicago branch to Room 1666, Conway Building, 111 W. Washington Street, under the management of Gardner J. Thomas.

The INDUSTRIAL ELECTRIC FURNACE CO., of Chicago, makers of the Snyder furnace, have shipped a 1250-lb. capacity electric steel furnace, together with the auxiliary electrical equipment, to Burn & Co., Calcutta, India, the largest iron, steel and foundry company in India. The purchase of this Snyder furnace shows the progressive tendency toward modern equipment and modern practice in that field.

The ASBESTOS PROTECTED METAL COMPANY of Pittsburgh changed its name on May 1st to the Aspromet Company. When this company was established, in 1905, its sole product was asbestos protected metal. Their initial product meeting with favor resulted in their complementing the same by adding to their line other building materials used and bought by the same people who use and buy asbestos protected metal. Now they have a complete line of building material specialties, many of which contain neither asbestos nor metal in their make-up. Thus, the descriptive name, Asbestos Protected Metal Company, which originally served them so well, became restrictive to the point of being misleading; hence the change.

Beginning to See Light

THERE were a number of gentlemen seated in discussion at the Crystalloid Club. That is not its corporate name, but the disposition of its Committee on Admissions to function as a permeable membrane against applicants for membership suggests the appellation. Among the company was one of the leaders of the New York bar. "There is a man," said he, "who calls at my office occasionally to collect money for a welfare organization, and I usually give him a little contribution, rather to get him to talk than for his cause. He travels all over the country and he is a very observant person. His comments are keen and I get more out of him than he gets out of me. The other day he was in a talking humor and I asked him how the people of the West or South feel about the war. 'You New Yorkers,' he answered, 'do not seem to appreciate how much alike the people of the country are: ours is the only nation in the world which is nowhere provincial. With the exception of certain colonies of foreigners that remain unAmericanized, the people of the United States are the same, not different. Whether I am here or in Buffalo or Chicago or Omaha or San Francisco or Galveston or New Orleans or Atlanta or anywhere else, the cities have a remarkable cousinship in appearance; the men are alike, each after his kind; they dress according to the same fashions and their habits of thought are very similar. Abstract ideas, unless they bear upon local conditions, are received in much the same temper all over the country. I do not mean to say that our cities or centers lack individuality, because Americans are too much alive to travel in herds or be dull, but they are nowhere provincial.

"'Take the news-stands, for example. Everywhere I find the same periodicals and in about the same proportions: the same little piles of literary magazines and reviews, the same larger piles of the cheaper ones, the higher stacks of the periodicals for women and the still higher ones of the *Saturday Evening Post*, with the usual proportion of Hearst's Lures of Sex for the Adolescent. The whole country reads the same literature, both good and bad, and discusses it. Now that is what holds us together: reading the same literature at the same time. It is what is backing up the country in the resolution to win the war. I take it that your friends are safe and loyal. Well, so are the friends of nearly anybody else, no matter where he lives, in the United States. Of course there are hot-beds of sedition and of German propaganda here and elsewhere, but they are getting about the same treatment in one place as in another. Think how little unity of interest there would be among our people if they thought only of their business; of what they produce! But they have

unity in literature, the literature of every day. These periodicals, which are so widely read, gather in sentiments from all over the country and spread them abroad. They make us laugh together and cry together. Where they are published is unimportant; it is the habit of writing in terms of the whole nation that makes them such great factors. And I really believe that if the zone system of postal rates is established, it will forbid national circulation, and there is serious danger that this will kill the very thing that has taken us so long to build up: the unity of the people. I cannot imagine a more insidious method than this to bring about provincialism and the envy and ill-will that is sure to follow it. It is a destructive attack upon the national community of mind.'

"I declare," continued the leader of the bar, "I believe the man was right." The others agreed with him and proceeded with unanimity to consider ways and means to combat the impending danger.

Furnace Slags in Theory and Practice

ONE sometimes resents the intrusion of the physico-chemical-minded metallurgist with his phase rule rudely unhorsing us from that simple hobby that our furnace slags are quasi-chemical compounds, and can be accurately termed singulo-, sesqui- or bi-silicates. Even before the advent of this scientific irritant, the hypothetical behavior of alumina was always a fly under the saddle blanket, and the pestiferous question as to whether it should be figured on the acidic or the basic side of the equation provoked reams upon reams of discussion. Fortunately the most of our furnaces worked calmly on, smelting high alumina and other unreasonable ores without waiting for the decision to be rendered, which probably will arrive the same day the disputants can find some definition of the terms "acid" and "base" which will apply at temperatures so far above the boiling point of aqueous solutions. At any rate, when furnace computation is sifted down to realities, do we not merely try to approximate some slag which experience has taught will be suitable?

Thus we sidestep the fundamental questions which the equilibrium diagram solves, and which chemical analysis alone is as incapable of solving as it was the age-old mystery of hardened steel. The researches of the scientists at the Geophysical Laboratory have blazed the way for a rational interpretation of the chemistry of silicates, and have proved, for instance, that in the ideal case of lime-silica slags only four chemical compounds exist in all possible compositions, from pure silica to pure lime, namely SiO_2, $CaSiO_3$, Ca_2SiO_4 and CaO. In such a series sub-silicates, sesqui-silicates, and tri-silicates simply have no objective existence. Again, the iron blast-furnace with its additional aluminous burden produces slags in which the stable entities are gehlenite and calcium metasilicate.

However, the laboratory metallurgist should not fail to visit his brothers in the cast-house regularly and often, going with the attitude of a student seeking information rather than that of an instructor dispensing wisdom. Else he will probably work a long time before he discovers that the furnace man consistently avoids the use of the slag composition which has the lowest melting point, primarily because it is so viscous that it cannot be handled. On the other hand, the furnace man believes (and he may very likely be right in his belief) that one of his biggest jobs is to get all the lime, magnesia, alumina and silica charged at the top to come out at the bottom, be it as $CaSiO_3$, Ca_2SiO_4, or what not. He likes to formulate some simple rule easy to work by (and who can blame him), such as "the higher the lime the more sulphur will go to the slag," bolstering it up with a nice reaction between calcium oxide and iron sulphide which balances neatly and looks good. But it isn't elastic enough to stretch over all the facts! In his dilemma, the works metallurgist, if he is friendly to the laboratory metallurgist, can get information to the effect that his rule is wrong simply because calcium oxide as such has not appeared in any furnace slag since the invention of the cinder notch, *except*—and here even the wise physico-chemico-metallurgist will have to venture on another voyage of discovery—except for the possibility that the silicates formed in the topmost part of the smelting zone may dissociate into chemically active entities under the intense heat of the focus.

Really, that is the fun of it! There is always something left to look into, always the unexplained to be explained!

Recognizing the Metallurgical Engineer

AT the last meeting of the Board of Directors of the American Institute of Mining Engineers the sentiment was formally expressed that a change in name of the organization would be desirable in recognition of that element of the membership concerned primarily with metallurgy as distinct from mining.

The proposal is not new, but the action of the Directors of the Institute is the first step toward crystalizing an opinion that has been held and frequently expressed by many. A census of Institute members would show but one-third primarily interested in and devoting their energies to metallurgy. On the other hand a classification of Institute technical literature would disclose a predominance of papers devoted to metallurgy. All this is by way of logical evolution from the time when the duties of the mining man were not only to dig the ore out of the ground, but to operate a stamp-mill or smelting-cupola as well. With the exploitation of low-grade ores and new ones not known or needed in the earlier state of the art, came the demand for expert advice in ore treatment; and with the later developments in the production and uses of ferrous and non-ferrous metals and alloys, a new phase of metallurgy developed which is growing in significance.

At the present time there is a bid for metallurgical allegiance to several organizations. There is the Iron and Steel Institute, which had some excellent technical papers on the program at its recent meeting in New York. The impression prevails, however, that this association is engrossed with the purely business aspects of the industry. To a metallurgist, the American Foundrymen's Association is more like a trade organization, from which the American Institute of Metals branched several years ago; but even the latter deemed it advisable to join the A. I. M. E. in a body, forming the Institute of Metals division. In addition

to these there are the Mining and Metallurgical Society of America, which functions most actively in New York City; the American Electrochemical Society, which comprises an eminent body of engineers skilled in electrometallurgy; the Steel Treating Research Society, comprising an important and growing class of men who supervise the toolmaking and control the quality of the product of progressive metallic-manufacturing establishments; and the American Chemical Society, which has proposed the formation of a metallurgical section on the score that metallurgy is chemistry applied to the treatment of ores and metals. This Society is now the largest in its field, having grown rapidly in the last few years. It has rendered excellent service in mobilizing the American chemists for war, and all members of the profession should rally to its ranks. It may lay claim to the allegiance of metallurgists, but in our judgment the rapidly expanding field of industrial chemistry offers a greater opportunity for predominance by this important organization.

Evidently there is need of concentration of effort and interest. We are fully alive to the difficulties in the way of inducing societies, once organized, to lose their identity by merging into a large central body. There will always be organizations, numerically small but professionally important, devoted to highly specialized phases of the metallurgical industry. Nevertheless, under the present circumstances we incline toward the idea of making an "American Institute of Mining and Metallurgical Engineers" the great representative body of American metallurgists. The action of the Institute of Metals has pointed the way, and we hope the prospect will be bright enough to attract iron and steel metallurgists who may have felt no interest in a society of mining engineers. With the change in name they can feel perfectly at home, can have their special meetings and aid in promoting the solidarity of the profession.

All Steel for War

A YEAR ago, when technically we had been at war for two months, estimates ranging from 15 to 30 per cent were being made as to the proportion of the country's steel output the Government could use for waging war. Now the Government is requiring that all the steel be diverted to war use.

There is a wide difference between the estimates and the realization, and the divergence is emphasized by the fact that the authorities at Washington intimate that if the steel industry could produce still more steel that extra amount would not constitute a "surplus" for general distribution, because Washington would find a use for it also.

Why this great divergence? The arts of war have not changed in a twelvemonth, nor did those who made the 15 to 30 per cent estimates have incorrect appraisals of the amount of steel a single ship or shell or gun would use. It was their viewpoint as to the participation of the United States in the war that was incorrect. The Government had declared the state of war and "the people" were going to "support" the Government in some intangible way—give the Government its countenance and sympathy.

The condition to-day, however, is that every man, woman and child in the United States is, or should be, helping in one way or another to conduct the work of war. With such a condition obtaining it is a relatively simple matter for the war to absorb all the steel. The machinery and labor that ordinarily fits the products of the steel mill for actual useful employment is being utilized or will be utilized to fit the steel for war use and the labor that ordinarily uses these finished products will now use them in waging war.

The railroads, which for decades have been the best single customer of the iron and steel industry, have been made a government agency to aid in the prosecution of war. All steel used by the railroads is war steel. The building industry, normally a large consumer of steel, has been mobilized for war. The structural shops, instead of producing fabricated steel for bridges and buildings, are turning out parts for fabricated ships and fabricated material for innumerable storage warehouses on both sides the Atlantic. The automobile industry will build many tens of thousands of army trucks and many thousands of passenger cars for the army. Agriculture, normally a peace industry, is now a war industry and requires steel just the same. The production of fuel has become a war industry, and it will consume more steel rather than less, in the coal mine and in oil and natural gas development and transport. The production of many minerals is to be stimulated as a war development. The building of ordinary dwelling houses, to meet individual desires of the people, stops of its own accord by reason of high costs of material and scarcity of labor, but when population migrates in order to engage in war work new housing facilities must frequently be provided, and that involves a considerable amount of dwelling house construction, strictly a war necessity.

This glance at what is occurring industrially suggests the viewpoint that the war has not absorbed the steel directly, it has absorbed the machinery, the implements, the men that normally handle, fabricate and consume the steel. If the war were absorbing only one-fourth the steel output as was at one time expected, who is there to use the other three-fourths? The difference between the forecast and the realization is due simply to the much greater measure of control the war has taken of the entire people.

Thus the picture that is sometimes sought to be drawn, particularly in the daily press, of how industries are to be deprived of steel, becomes a very vague and shadowy one. In general, they are not deprived of steel to any greater extent than they are deprived of the opportunity to work with it, if they received it for ordinary uses, and sell the manufactured products that would result. The dislocation, or to use a word with a much better ring, the alteration, is not simply in the distribution of steel, but in all the activities of the people.

It might be impossible to effect an alteration sufficient to consume all the steel, seeing that this amount is to more than 30,000,000 gross tons a year, measured in the form of finished rolled steel, when prior to the war the production less exports was only about 20,000,000 tons; but our Allies have capacity to use much more steel than they can produce, and the shipping situation is such that we can transport a very large tonnage of steel to them.

Readers' Views and Comments

Intensive Toluol Production

To the Editor of Metallurgical & Chemical Engineering

SIR—In view of the great improvements in the recovery and manufacture of toluol carried out in this country since the war began, I was keenly interested to read the views of Mr. Lichtenhaeler in his article on "Intensive Toluol Production" in your issues for Feb. 1 and 15. The experiments and developments recorded are indeed worthy of the traditional thoroughness and skill of American engineers and chemists, but I may be pardoned in taking exception to a few of the principles as set forth in above article.

Under "Developing of Resources," questions of supplies are divided into three main arteries, crude petroleum products coming under item No. 3.

The writer has had considerable experience in the manufacture on a commercial scale of toluol from petroleum products, experiments being carried out with kerosene and fuel oils, and it can be definitely stated that at the present there is no "cracking" method which will give a satisfactory aromatic toluol. In the first place the approximate yield of pure toluol obtainable from crude oil is not more than 2½ per cent by volume, and actual costs including sale of by-products, such as gas, motor-spirit, etc., to produce one gallon of toluol in Great Britain was about $7.50. It is the writer's opinion that no method has yet been invented which is capable of yielding a toluol absolutely free from paraffins or cyclo-paraffins, which bodies tend to widen out the boiling range of pure toluol, and as proved by commercial-scale fractionation 0.5 deg. toluol cannot be produced from such sources, the same remarks applying to toluol from water-gas tar, or vertical-retort tar.

It is quite possible that the toluol produced distilling over a range of say 2 deg. C., can be nitrated and any paraffins or cyclo-paraffins separated by simple distillation. However, the presence of a small percentage of impurity such as the above has a tendency to detrain benzol into the toluol fraction, and this benzol seriously interferes with the resulting nitrated product, the merest trace of nitrated benzol in the nitrated toluol product causing the lowering of the melting point with consequent difficulty in the manufacturing process.

Referring to Fig. 1, it would be interesting to know how this process can be applied to coke oven plants or gas works dealing with say 2 to 5 million cubic feet of gas per day, as the cooling surface, etc., required would be enormous, and the plant as shown would require to be considerably modified in view of the necessary staging required.

With reference to the various efficiencies of the hurdle type of absorber, the "cap and bell" absorber and mechanical absorbers, the writer has had considerable experience in this direction, and can say with all confidence that the following are the relative efficiencies when operating on coke-oven gas and extracting benzol by means of creosote oil:

The hurdle type of scrubber has an efficiency of approximately 80 per cent. The cap and bell absorber, 85 per cent. Centrifugal scrubber of the MacLaurin patent type, 90-95 per cent.

The above figures, of course, refer to the standard sizes supplied for equal capacities of gas per hour, and I am at a loss to understand how the "cap and bell" scrubber, or any other type of scrubber can use a less quantity of oil if maximum recovery efficiency is to be obtained, as in all scrubbing and absorbing processes the efficiency of recovery is entirely dependent on the temperatures of the gas and scrubbing medium and the relative vapor tensions of the compound to be recovered in the absorbing medium and in the gas.

The so-called Carpenter process as employed in Great Britain was an emergency method put into operation at various small gas works which have not the necessary plant and apparatus to recover their benzol and toluol by the creosote oil absorbing process. It must be clearly understood that the calorific scale for the sale of gas is not universal in England, the photometric scale being more predominant, and in most cases the quantity of toluol recovered with tar as an absorbing medium is only 50 to 60 per cent of the actual quantity present in the gas. Most large concerns and coke-oven plants use creosote oil for benzol recovery, and it can be said without fear of contradiction that should the plant be so designed as to allow maximum heat interchange, etc., and careful control exercised, the absorbing oil will last easily two months. Due regard must be given to the back pressure which would undoubtedly be thrown on the exhauster by means of the "cap and bell" absorber as proposed, which from the illustration given, probably will amount to at least 30 in. water gage. Gas managers in the majority of cases would be unable to cope with such enormous resistance, and a scrubber is required, such as the MacLaurin centrifugal scrubber type which does not throw a back pressure on the plant of more than 1 in. water gage, whilst also giving definite relation between absorbing medium and the gas to be treated.

I question the statement whether the hurdle tower requires any more oil as stated than any other scrubber. Creosote oil as a washing medium is undoubtedly the most efficient for the recovery of benzol, and the loss in circulation is extremely small, whilst the price for spent oil approaches that of the fresh oil originally supplied to the plant.

Against the advantages of tar as an absorbent as set forth, we might state that for the same quantity of tar and creosote oil circulated, the former only gives a recovery efficiency of from 50 to 60 per cent, whilst the latter in most cases give 80 per cent, depending on the concentration of the benzol in the wash oil to a large extent, which normally approaches 4½ to 5 per cent.

Most gas and coke oven plants are not fitted with plant to distil their own tar, and should all the toluol and carbolic be recovered as stated, the price of the tar as sent to the distiller will be lowered proportionately. Should a shortage of absorbing oil at any time occur it is possible to substitute same by tar as

produced in the plant, and should this contain an excessive quantity of water, it would be entirely separated in a centrifugal scrubber, having the effect of washing the gas in two stages with water and tar respectively. With a good design of fractionating column and still, very little absorbing oil is carried over with the crude benzol, and in most cases does not amount to more than 5 per cent.

The type of still as shown, having closed steam coil in every section with open coil at the bottom, is now obsolete owing to the enormous wear and tear and erosion on these coils by the cyanogen sulphides and ammonia present in the tar and crude benzol, and which are evolved when subjected to the temperatures of distillation.

The most satisfactory method, and one which has been carried out and improved by the writer's firm, consists in preheating the ingoing oil and then superheating same by steam, passing back vapors and oil into the still separately, the oil being subjected to treatment with a very small amount of open steam, amounting to not more than 2 lb. per gallon of benzol recovered.

It is a moot point whether direct-fired stripping stills hold any advantage over the improved steam-heated type of plant, as the resulting benzol from the former contains a fairly large proportion of entrained higher boiling homologues in view of the absence of any fractionating device. Great risk of fire is also a drawback, and the wear and tear on the still through direct firing and the action of noxious gases is fairly high.

With regard to Article II, it might be stated that we have now had continuous stills in operation for a number of years and designed a complete continuous benzol refinery over twelve months ago (See "Gas World" 1917). With this type of plant it is possible to treat crude products with varying boiling ranges, as these are satisfactorily fractionated to standard products, which can easily be refined with very little still control, being fairly constant in composition. It is a practice in this country to treat say a coke-oven benzol distilling 65 per cent at 120 deg. C., (old retort test) and fractionate same into crude 90's benzol, crude 90's toluol, crude 90's solvent naphtha, crude 90's heavy naphtha, the various products oeing washed separately and fractionated through the continuous refinery and either 90's refined government standard or pure products manufactured in one continuous operation. Such treatment requires efficient columns and dephlegmators for the production of a compound such as pure benzene distilling 90 per cent over 0.5 deg. C. We have designed a new type of horizontal tubular dephlegmator in which the vapors pass through the tubes in a counter-current direction to the cooling water, thus ensuring maximum fractionation and gradual washing effect from the heavier condensed bodies. All returns, etc., are external, and same are easily cleaned in case of chokage by means of naphthalene or other deleterious matter.

With regard to the chemical treatment of crude benzol, this is bound to vary according to the source of the product, and no fixed basis can be taken.

When benzol or toluol is subjected to chemical treatment with sulphuric acid, should any toluol disappear, it is reasonably assumed that same has combined with the acid and formed a sulphonic compound. It is now possible to recover all the unsaturated bodies and aromatics which are lost in this manner. The acid tar is treated in the lead-lined vessel with open steam which decomposes the sulphonic bodies, which are carried over and condensed in special type condenser and subsequently separated and re-washed. The acid recovered amounts to approximately 90 per cent of the quantity used, only, of course, in a dilute condition.

Centralized refining must depend to a large extent on the freights charged for transport of crude benzol, but such a proposal undoubtedly calls for serious consideration after the war. B. DUNGLINSON.

Central Stations and the Manufacture of Electrochemical Products

To the Editor of Metallurgical & Chemical Engineering

SIR:—No one who is in touch with the situation can entirely disagree with Mr. Winder as to the conclusions he reaches in his address on "Central Stations and the Manufacture of Electrochemical Products," published in your April 1st issue. His view that the power company which undertakes to furnish steam-generated electric power for an electrochemical industry labors under a serious handicap, is correct in part, for the reason that a 24-hour load accentuates the weakness of its high operating costs and minimizes the strength of its relatively low installation cost. This is especially true today when both installation and operating costs of the steam plant have soared to a much greater degree than has been the case with water-power plants.

Mr. Winder's discussion, however, is marked by one regrettable characteristic which has, as a rule, been common to similar discussions from the point of view both of the electrochemical manufacturer and of the central station industry, the apparent desire to prove a case rather than to learn the truth. As an electrochemist connected with a central station company, the writer feels privileged to criticize this attitude, which has, in the past, characterized both sides of the argument. An impartial statement must be based on all the facts and there are a great many facts to be considered from both points of view. General statements are dangerous because they are seldom based on a sufficiently comprehensive survey of the field as a whole. An analysis of the requirements of each electrochemical industry considered with relation to its possible use of steam-generated power in various parts of the country would be of great value, but such an analysis is difficult to make, and when made does not find its way into print.

The central station man who attempts such an analysis is faced by the fact that a great deal of absolutely essential information is unavailable, because it forms part of the secret stock-in-trade of the electrochemical manufacturer. The electrochemist who attacks the problem from the opposite point of view, although he has this information, will find that he cannot reach the solution without the assistance of someone who has a broad knowledge of central-station rate-making and the details of power supply as practiced by variously situated central station companies. Unless he is very careful

he will fall into the error of reaching general conclusions based on partial information.

Several errors of this nature have crept into Mr. Winder's article. He states broadly that, since central station companies do not produce 25-cycle power and such power is required by most electrochemical industries, this feature "practically precludes the present day central station from entering this field" (with particular reference to ferrosilicon manufacture). On the contrary several large central stations produce 25-cycle power and are prepared to sell it to anyone who prefers it. Mr. Winder implies that any power-factor much below 90 per cent is unacceptable to a central station company and that such a power-factor will increase the cost of power to the customer. As a matter of fact power-factors above 70 per cent are seldom penalized and one large power company, which penalizes any power factor below 60 per cent, gives a corresponding bonus for a power-factor above that value.

The off-peak rate is designed for use by the customer who can use such a rate to advantage, not for the industry which needs to maintain a 100 per cent load-factor 24-hour load. In Chicago the 24-hour load earns a rate very nearly as attractive as an off-peak load of similar proportions and the restricted peak period includes only four hours per day, four months in the year. The 24-hour load is nearly, but not quite, so desirable from the power company's point of view as the off-peak load, and the rate is fixed accordingly. Surely, under such circumstances, it is hardly fair to speak of "a twenty-four hour load undoubtedly penalized from a bookkeeping standpoint in favor of the domestic consumer," or to refer to "the inability of steam stations to make consistent rates for twenty-four-hour power."

When the economic value of power sources is being considered, the importance of their location must by no means be neglected, but when it is stated that the artificial abrasives industry cannot "stand more than a five-hundred-mile haul under the prevailing prices of water power," one begins to wonder. Where do the industries of the Middle West get their abrasives or are they still using the natural product? What portion of the United States can afford to use carborundum made at Shawinigan Falls? On this same 500-mile basis, isn't it possible that steam-generated power could profitably be used to manufacture abrasives to supply a well developed industrial territory situated more than 500 miles from the nearest developed water power available for this purpose?

The writer does not claim to know that steam-generated central-station power can be used economically in any wide degree by the electrochemical industries. To speak frankly, he doesn't know and hasn't so far been able to find out. Favorably located central-station power can be purchased in large blocks for from $50 to $60 per kilowatt-year, if it is to be used at a load-factor of 90 per cent or better for 24 hours per day; but that doesn't answer the question, nor does a learned discussion of freight rates fill the gap in the required information. What are the relative costs of the different factors involved in the various sorts of electrochemical manufacture? As those manufacturers are now conducted, what proportion of the total cost is represented by the bill for electric energy? Those who know won't tell and it doesn't pay to guess.

From some of the discussions of this subject which have been published one might assume that electrochemical industries, as a class, are burdened with power charges which form 50 to 75 per cent of their total cost of manufacture and distribution. But is this assumption a safe one? For example, consider the case of aluminium, which requires some 12.5 kilowatt-hours for every pound of metal made, and which Mr. Winder very properly specifies as "perhaps more dependent upon the low cost of power than any of the other above mentioned products." And yet, it is something better than a wild guess to estimate that the cost of carbon electrodes consumed per pound of aluminium is nearly as great as the cost of electrical energy, at the rates usually paid for energy in that industry.

One would suppose that the proper method to pursue in ferreting out the answers to all these questions—assuming that it is really desired to answer them—is for the electrochemical industries and the central station companies to get together for a full and frank discussion of the variables involved and their relative importance. A beginning along this line was made last year when a joint committee was appointed by the American Electrochemical Society and the National Electric Light Association, for the purpose of considering this very subject. The first report of this committee, however, does not give the impression that very much progress was made. Perhaps it is too much to expect that much progress can be made in a public discussion of economic matters, the true details of which are shrouded in secrecy and jealously guarded. The writer ventures to predict, however, that no general conclusions worthy of consideration will be arrived at, until our arguments pro and con, are based on the facts, all the facts there are, and nothing but the facts.

Long-Range Bombardment of Paris

To the Editor of Metallurgical & Chemical Engineering

Sir:—The first day of the bombardment of Paris by the long-range German gun followed a night of bombing by enemy airplanes. No one at that time realized that shells were being sent into the city from a point behind the front-line trenches which are at least 75 miles from the center of the city. I was out on the streets the morning the bombardment began and everybody was under the impression that it was a *daylight* air raid, something entirely new, as of course all of the previous air raids had been engineered under cover of darkness. The sky above Paris was thick with French fighting planes, scooting here and there in search of enemy machines. It was not until late that day that we realized that the explosions did not come from bombs. The excitement was intense and everyone was mystified, for explosions were occurring at regular intervals of about twenty minutes, and no enemy machines could be spotted overhead.

The regular *alerte*, which is a warning sounded at the approach of German bombing machines, was given early in the morning, and both the "Metro" and the "Nord-Sud" the two Paris subways, were shut down in order that the stations platforms and underground tubes could be used as a refuge by the people of Paris. The

street railways stopped operation. Cars were emptied, motormen and conductors left their platforms, and the rolling stock was left standing in the street wherever it happened to be when the *alerte* was given. Traffic was absolutely paralyzed and the only wheels turning were those of the taxicabs.

As a matter of fact the shutting down of the subways in order to furnish underground retreats for the population defeated the very purpose for which it was done. In an hour or two people got tired of staying under ground and came up for a breath of fresh air. Many of them had to get from one part of the city to the other, and the only way of doing this was by walking along the streets. Therefore, with the subways shut down, there were far more people on the streets and subject to danger from explosions of shells than would have been the case if the lines had continued their normal operation. This fact evidently was appreciated later, for during succeeding bombardments by the long-range gun, the subway system has continued in operation.

The damage done by the long-range gun is much less than that which results from the dropping of bombs by an airplane. I have seen a good many of the buildings hit by the long-range shells and they seem to damage only the two upper stories. The bombs, however, wreck things to a greater depth, sometimes as much as four stories. It often happens that when a shell strikes, the panes of glass on the opposite side of the street are shattered, while those on the same side remain intact.

Detonations of explosives are such a regular event here that the store-keepers are going to great trouble to protect their windows from breakage. The favorite stunt seems to be to paste across the glass long strips of paper. It seems to me that these Parisian shop-keepers have something to learn in the matter of window protection from New York merchants, whose stores were situated along the excavations for the new subway lines. There it will be remembered the favorite trick was to truss the panes with diagonal wires and struts at the center. I have yet to see one of these rigs in service here. The gummed strips of paper, however, apparently have official sanction, for the windows of the Ecole Nationale des Ponts et Chaussees are dolled up in this way.

The city authorities are busy providing shelters or *abris* for the people during air raids. These are generally cellars of buildings not less than four stories in height. On the entrances to buildings containing cellars which have been officially designated as *abris* are big paper placards indicating the capacity of the shelter. Going along any street in Paris now you see on the buildings these placards with the words "150 places," "80 places," etc. Some of the cellar *abris* had window gratings fronting on the streets. At the present time all of these are being blocked up with plaster to intercept shell splinters.

Although the subway is now kept running during daylight bombardment by the big gun, it is closed during an air raid at night. Those people who seek underground shelter on such occasions now take the experience pretty much as a matter of course and during the last raid I saw people filing down stairs into the Etoile station of the "Metro" with camp-stools, chairs, newspapers and magazines, and other aids to comfort during the two or three hours sojourn below street level.

When a night raid starts the fire engines are sent at full speed through the streets with their sirens going full blast, church bells outside of Paris start ringing, and factory whistles add to the discord. New stationary sirens are in course of installation. Pretty soon the anti-aircraft guns start booming on the outskirts of Paris and from my window I can see the flash of the shells as they burst in mid-air. It looks just like the bunch of sparks produced in grinding metal with an emery wheel. In twenty minutes or so after the guns have started the airplanes which have managed to break through the barrage begin to "lay their eggs." It is very easy to distinguish between the detonation of bomb and the burst of the shrapnel from the "Archies." The bomb makes a deep long roar while the shrapnel produces a higher stacatto note.

An American where I am living arrived just in time to get in on one of the air raids. It was his first. The next morning he had a decidedly haggard look and I asked him what was the matter. He looked out of the window and seemed to be surprised that there was anything left of Paris. "They must have dropped about a thousand bombs last night," he said to me. I could not quite figure this out, as this was one of the nights that the bombing machines had failed to cross the barrage. Finally it dawned upon me that he had assumed to be bombs the detonations of the hundreds of shells which had been fired by the French artillery on the outskirts of the city to form the protective barrage. No wonder he was upset, as there must have been a good many hundred shrapnel fired that night. If these had been boche bombs I probably would not be writing this letter now.

Paris is not greatly disturbed by the shelling of "le canon a longue portee" which is generally dubbed by the French newspaper writer as "la grosse Bertha." People go about their business very much as usual. The moving pictures are taking a crack at the big gun in a humorous way. At the last performance I attended there was shown an "animated cartoon" in which "la grosse Bertha" was sending over shells and Charlie Chaplin (whom they call "Charlot" over here) was catching them, standing forth as the defender of Paris. After he had caught three of these the cartoon showed him juggling them, and finally hurling them back in the direction of Berlin.

While many people have departed from Paris as a result of the air raids and bombardment, the bulk of the population is taking the matter calmly. I have yet to see anything in the nature of a panic. At the pension where I live there is an elderly widow of a French general; she must be at least 70. When the bombs begin dropping she always goes through the motions of a mock courtesy in the direction from which comes the sound of the explosion. Only one or two of the crowd here seek refuge in the cellar. On several occasions they have tried to induce the old lady to descend with them, but she stands her ground, and all they can get out of her is, "Je reste ici."

Western Metallurgical and Chemical Field

Certain Influences on Electrochemistry and Metallurgy in California

The California Railway Commission has been conducting a comprehensive investigation into the need of immediate hydro-electric development to meet the special power consumption of war industries and the normal growth of the community. Their first report as to conditions in the southern part of the state shows that in that region an annual increase in hydro-electric plant capacity of 25,000 kw-hr. will be necessary to keep the oil consumption down to the present figure, and consequently recommends that the operating companies take immediate steps for financing these extensions to the extent of perhaps twenty million dollars. With promptitude and proper priority orders, this annual extension can be provided.

It is perhaps trite to remark that much of this shortage as well as the crying needs of nitrogen fixation and other electrochemical products would now be covered had not hydroelectric development been practically stationery throughout the United States for five years, on account of the lack of a comprehensive national water-power policy. The effect on present and future electrochemical and metallurgical industries in California is also obvious. In Secretary Lane's words, "It is quite manifest to me that there has got to be a very large electrical development if we are going to have the largest development along the lines of chemistry, and perhaps the best sphere for a young man for the next twenty-five years will be as an electro-chemical engineer in the United States. The water powers ought to be put into use now, not only with the idea of taking care of plants that will be commercially successful propositions, but with the purpose of experimenting and discovering what can be done." That the possession of developed water power is an asset of national importance in unexpected ways is shown by the effect of turning unsold power into ferro-manganese at Great Falls. This production will react favorably on the national railway and shipping situation, mining activity in the West, and steel production in the East.

Canadian Mineral Production

A preliminary report on the mineral production of Canada has been issued by John McLeish, Chief of the Division of Mineral Resources and Statistics of the Canadian Department of Mines. He notes that the metal production of 1916 showed a very large increase over that of the previous year, but in 1917 the net result in value has been an increase of only one-third of one per cent. The interrelation of the industry is shown by the effect of a diminished coal and coke output on the metallurgical production; the falling off in production of copper and gold is in part attributable to this cause. The accompanying table gives a view of the situation as a whole, both as to value and quantity.

The British Columbia production of copper amounted to 57,717,535 pounds; Ontario produced 42,796,213, derived chiefly from the nickel-copper ores of the Sudbury district, supplemented by a small recovery from the Cobalt silver ores.

Of the gold production, 27.5 per cent was derived from placer mining, 61 per cent in bullion and refined gold, and 11.5 per cent was contained in matte, blister and residues. Ontario produced 58 per cent of the total; British Columbia's production of $2,776,558 registered a decrease of nearly 39 per cent from that of 1916, due not only to the high cost of supplies but also in part to labor troubles and the closing down of the Rossland mines for several months. Yukon Territory produced $3,671,008 in gold, which is a decrease of over 16 per cent.

The lead production is largely from the Trail smelter in British Columbia, and the figure includes 30 million pounds of bullion, of which a large portion was electrolytically refined.

The 1917 production of nickel has, as usual, been derived from the ores of the Sudbury district, supplemented by a small amount of byproduct metal and compounds resulting from the treatment of the silver-cobalt-nickel ores of Cobalt. The Canadian Copper Company and the Mond Nickel Company produced 78,897 tons of nickel-copper matte, containing 83,773,319 pounds of nickel, and 42,392,588 pounds of copper, resulting from the smelting of 1,453,661 tons of ore. The refinery of the International Nickel Company at Port Colborne has not yet been completed, while the smelter and refinery of the British American Nickel Corporation near Murray, Ontario, is progressing slowly. Nickel to the extent of about 700,000 pounds was also recovered as a by-product from Cobalt ores in smelters at Deloro, Thorold and Welland.

Ontario produced 19,254,616 ounces of silver practically exclusively recovered from the ores of Cobalt and the adjoining silver camps. British Columbia produced 2,580,521 ounces.

During the past two years there has been a recovery of refined zinc in Canada at the zinc refinery erected at the Trail smelter, whose establishment has resulted in a largely increased tonnage of ores mined. The total zinc ore shipments from the mines were about 116,660 tons, containing 61,920,149 tons. Of this, British Columbia produced over 30 million pounds.

The pig-iron production by grades was as follows: Bessemer, 961,656 tons; basic, 14,092 tons; foundry and malleable, 181,041 tons; electric furnace pig, 15,000 tons approximately. No new construction of blast furnaces occurred, and the production of blast furnace pig fell off slightly. On the other hand a small production of high grade, low phosphorus pig iron was furnished from electric furnaces melting down shell turnings and other steel scrap, the salvage of which by this method promises much in the future.

The blast furnace plants operated were the Dominion Iron & Steel Company at Sydney, N. S., the Nova Scotia Steel & Coal Company, at North Sydney; the Standard Iron Company at Deseronto, Ont., The Steel Company of Canada, at Hamilton, Ont., The Canadian Furnace Company, at Port Colborne, Ont., and the Algoma Steel Corporation at Sault Ste. Marie, Ont.

Pig iron was made in electric furnaces by: The Canada Cement Company, Ltd., Montreal; Frazer, Brace & Company, Ltd., Shawinigan Falls, Que., British Forgings, Ltd., Toronto, Ont., Electro Foundries, Ltd., Orillia, Ont., and Turnbull Electro Metals, Ltd., St. Catharines, Ont.

MINERAL PRODUCTION IN CANADA

	1916		1917	
	Quantity	Value	Quantity	Value
Antimony ore, tons	885	$94,537	774	$50,476
Antimony refined, lb.	107,185	41,823		
Cobalt metallic and contained in oxide, etc., lb.	840,536	924,590	1,089,134	1,742,614

Manganese Concentrator at Philipsburg, Montana

A new system for the treatment of western manganese ores has been established by the Philipsburg Mining Company at Philipsburg, Montana, in a mill of 350 tons capacity. The mill has been in continuous operation since January 15, 1918, under the direction of Mr. R. S. Beitz, superintendent, and is doing exceptionally good work. The flow-sheet as operated at present is as follows:

The ore occurs in a limestone formation and the manganese is contained chiefly as a nodular variety of pyrolusite and psilomelane. It is brought from the mines a distance of approximately one and one-half miles in six-horse wagons holding between six and eight tons, and is dumped on a platform under which runs a 22-in. conveyor protected by an 8-in. grizzly. This conveyor elevates the material to a second grizzly having 2-in. spaces—the larger rock going to a No. 4 gyratory crusher and thence to the coarse-ore bin. The material under 2 inches is fed by a 22-in. conveyor to trommel No. 1, covered by 1½-in. round punched plates. This trommel revolves at 16 r.p.m. with a heavy spray of water thrown from all directions on the ore, washing the clay and sandy limestone from the coarser pieces.

The oversize from No. 1 trommel passes to a picking belt where two sorters reject the waste and lean ore; this reject returns to a set of 36-in. by 16-in. rolls, while the balance passes on to the coarse concentrate bin. The undersize from No. 1 trommel goes to the No. 1 elevator and is carried thence to No. 2 and No. 3 trommels. These trommels are identical, being covered for the first half by a ⅝-in. round punched plate, and the remaining with ¾-in. round punched plate. All the trommels in the mill are heavily sprayed with water.

The undersize from the ⅝-in. screen passes to No. 4 trommel, while the undersize from the ¾-in. screen goes to two double two-compartment Hartz bull jigs. The oversize from No. 2 and No. 3 trommels passes to the 36-in. by 16-in. rolls crushing the picking-belt reject, which operates in closed circuit with No. 1 elevator and trommels Nos. 1 and 2.

No. 4 trommel is covered with a four-millimeter round punched plate; the undersize passes to No. 5 trommel, and the undersize goes to one double two-compartment Hartz middling jig.

The No. 5 trommel is covered with one-millimeter diagonal slot screen; the undersize passes to a 10-ft. cone tank for dewatering before feeding to tables, while the oversize passes to two double two-compartment Hartz fine jigs.

The tailings from the jigs are returned to the 36-in. by 16-in. rolls and are reground, eventually appearing as table feed. The cup concentrates from the two bull jigs, together with the cup and hutch product from the middling and fine jigs are dewatered by a Dorr thickener, and then elevated to a steam-pipe dryer above the fine concentrate bin. The hutch product from the bull jigs is treated on one No. 5 Wilfley table; and the tailings from the middling and fine jigs are treated on three No. 6 Wilfleys. The fine sand which comes over the Dorr thickener is settled and again treated on one No. 6 Wilfley. The table concentrates pass to a conveyor and are elevated to a bin; the middlings and tailings go to waste.

A fair average of the assays is:

Heads, Mn 32%, SiO_2 35%; washed ore, coarse, Mn 41%, SiO_2 18%; concentrates, Mn 49%, SiO_2 9%.

Work of the Seattle Station, Bureau of Mines

The Pacific Northwest Experiment Station of the United States Bureau of Mines at Seattle is investigating electrometallurgical and ore dressing matters in cooperation with the College of Mines of the University of Washington, the School of Mines of the University of Idaho, and the Oregon Bureau of Mines and Geology, under the general direction of Thomas Varley, Superintendent.

The electrometallurgical laboratory is in charge of F. C. Ryan, and is equipped to make both electrolytic and thermoelectric investigations. The electrolytic apparatus consists of a 5-hp. motor-generator set capable of giving a current range of from 0 to 100 amperes and a voltage range from 0.25 to 15 volts, together with auxiliary equipment to take care of combined leaching and electrolytic problems.

The electrical equipment of the thermoelectric laboratory consist of two 140-kv.a. single-phase transformers with voltage regulators to give a range from 35 to 480 volts with transformers in single-, two-, or three-phase position, together with the necessary meters and pyrometers.

Field investigations in this department include a review of the present status of electrometallurgical plant development in the Pacific Northwest and southeastern Alaska, studying the general character of the work, equipment, and operating conditions. During the past year laboratory investigations were made on the utilization of metals from waste tin cans, and this problem is now well in hand. Investigations of ferromanganese and ferrochrome and other ferroalloys have also been made, the experiments being made on a small scale with the idea of experimenting on a large scale later.

Will H. Coghill, metallurgist, has carried on a study of the principles of ore flotation, the physical properties of oils being investigated and their modifying effect upon the surface tension of water determined. These surface tension tests are made with a "drop-weight" apparatus, which is essentially a dropping device provided with a brass tip, wherein the weight of the liquid drop that breaks from the tip gives a measure of the surface tension. The "capillary rise" method is unsatisfactory, but the drop-weight method, based on the well-known law of Tate, is so reliable and accurate that it should become better known. These tests have shown that the surface tension effect of oils is much less than the early technical literature would lead one to believe.

Another subject of investigation is on the angle of

contact between the liquid and the solid. This is recognized as one of the measures of "flotability"; many determinations are therefore being made and the theoretical and practical flotability of various solids on tranquil liquid surfaces are being compared. It has been determined mathematically that a solid, if not too large, is flotable when the angle of contact is greater than zero. Actual tests on tranquil surfaces have confirmed this analysis, but its relation to agitated surfaces is yet to be investigated. The so-called hysteresis angle is also receiving attention.

Work on gravitational ore-dressing has been under the direction of the superintendent of the station, Mr. Varley. During the past year a great many tests have been made on the massive copper-nickel pyrrhotite ore from Alaska, the idea being to make a separation of the copper and nickel from the related gangue. To date this work has been satisfactory as far as the copper is concerned, and some progress has also been made in recovering the nickel in a high-grade concentrate.

Following a visit to the Black Hills a number of samples of tin ores of that region were tested to determine what could be done in the way of recovering the cassiterite by concentration. At the present time very encouraging concentration tests are being made on low-grade chrome ores from Washington, Oregon and California. The same may be said of investigations now in progress on many of the quicksilver ores from plants in California which are using concentration as part treatment.

The work at the School of Mines at Moscow, Idaho, in charge of C. A. Wright, has been along the lines of preferential flotation, and consists of tests on the complex lead-zinc-iron ores of the Cœur d'Alenes. This work is made possible by the operators of the district who assisted in financing the work. The laboratory here has been made thoroughly up-to-date, and at the present time is one of the best equipped for ore-dressing in the West.

Company Reports

Consolidated Arizona Smelting Company.—The concentrator treated 106,226 tons of ore (an increase of 32½ per cent over that of 1916) containing $2.19 in gold and silver and 2.976 per cent copper. The recovery amounted to 90.4 per cent of the copper values, and 75 per cent of the gold and silver, with a concentration ratio of 3.14 to 1. The total cost of milling was $1.776 per ton of material treated, being 27 cents greater than in 1916, which increase was caused by the increase in wages and higher prices for nearly all kinds of supplies, but even to a greater extent by the attempt to fine-grind a larger tonnage that the equipment permitted, and the delays and repairs which naturally resulted. Additional ball mills are to be installed shortly to further increase the tonnage and improve the grinding and will also improve the recovery in the flotation machines. The total tonnage of new copper-bearing material smelted was 138,781 tons, an increase of 34 per cent over 1916 and 100 per cent over 1915. The production amounted to 9485 ounces of gold, 251,670 ounces of silver, and 19,751,042 pounds of copper. The average grade of smelter charge continued to show an increase in gold, silver and copper, the latter being now 7.85 per cent. The cost of producing copper has increased from 13.92 cents in 1914 to 14.98 cents in 1917. In conducting the custom smelting it is possible to equalize this advance by increasing the smelting charges. In purchasing custom ores the company endeavors to buy the copper and silver at the prices it expects to receive from their sale on the assumption of normal time in transit. Delays in the transportation of the blister copper to market during 1917 occurred when the market was falling, and the actual loss from this cause was approximately $120,000. Smelting costs, as shown in the accompanying table, are in part directly dependent upon the equipment. The steadily improved equipment has proportionately counteracted the other factors working even more strongly to increase the costs. Wages have increased 50 per cent during the last three years and coke has more than doubled.

Year	% Recov. Copper	Cost Crush. Receiving Samp. Stor. per T.	Cost Roast. & Reverb. Smelt., etc.	Cost of Convert. per lb. Copper Convt.	Cost of Frt. Ref. & Mktg. per lb. Copper Produc.
1913		$0.959	$4.097	$0.0137	$0.0139
1914		1.094	4.687	0.0058	0.0136
1915	83.978	0.543	2.844	0.0046	0.0153
1916	86.46	0.539	3.494	0.0072	0.0173
1917	90.70	0.489	4.200	0.0093	0.0218

The most serious failing of the smelter has been the heavy loss in metallurgical and mechanical dusting. Lack of roasting equipment has been remedied by the construction at a cost of $298,000 of four Wedge furnaces with Cottrell treaters, and an efficient system of belt conveyors. Over $100,000 was spent in remodeling and improving the equipment of the smelter, installing a third converter and a new crane, resulting in an increase in converting capacity of over 25 per cent. At Humbolt much work still remains toward improving living conditions. The company has always been seriously handicapped by inadequate and inferior living accommodations which have made it difficult to secure and retain the services of the best class of employees, and this condition has been emphasized by the recent influx of married men taking the place of the single ones who have been drafted.

North Star Mines Company.—A total of 126,474 tons was mined and delivered to the sorting plant, which eliminated 25,974 tons as waste, leaving 100,500 tons of ore which yielded values of $11.43 per ton, and a tailing containing about 40 cents. Of these values, 82 per cent were recovered by amalgamation and the balance by cyanidation. During the year $61,600 was expended, largely in equipping the Central Mill with sixty 1,500-pound stamps, and the enlargement of the Central Cyanide Plant, to perform the work formerly done by two 40-stamp mills with separate cyanide plants. The costs were as follows:

Milling	$0.611
Cyaniding	.458
Tailing Disposal	.028
Bullion	.034

on the basis of per ton crushed. G. B. Agnew, president of the company, remarks: "The purchasing power of gold has materially decreased each year of the war, with the result that the business of gold mining, generally has been seriously affected, and should the cost of supplies continue to rise, it is possible to foresee a situation where the Government might find it necessary to take measures to protect or to assist this important industry."

Hollinger Consolidated Gold Mines, Ltd.—This report shows a satisfactory financial progress, since in spite of the general shortage of competent labor a deficit of $269,590.93 existing on Jan. 1, 1917, has been converted into a surplus of $712,724.00 while during the year plant expenditures amounted to $673,237.52 (largely due to increasing the capacity of the mill at Timmins, Ontario, to 2500 tons per day) and $100,000 were written off for plant depreciation. Large additions to the physical equipment are now about completed, and its valuation amounts to $2,333,083.84. The mill worked at reduced capacity, treating all the ore which the mine was able to supply. Labor conditions were decidedly bad, especially during the first part of the year. Many of the miners are alien enemies, and while the average number of men employed was 1045, approximately 2700 men were hired and paid off during the year. Wages range from $4.00 to $8.00 per day. The report contains an unusually detailed distribution of expense, which would repay study, but which cannot be presented owing to lack of space. A comparison of operating results follows:

	1917	1916
Tons milled	514,301	601,584
Percentage of possible time running	70.2	91.1
Tons per 24 hours actual running	2007	1810
Stamp duty per 24 hrs. running	15.4	16.7
Solution precipitated per ton ore	2.15 tons	2.221
Average value per ton milled	$8.60	$8.84
Values in one ton of tailing	$0.31	$0.38
Cyanide consumed per ton ore	0.448 lbs.	
Zinc consumed per ton ore	0.36 lbs.	0.405
Lime consumed per ton ore	2.257 lbs.	2.113
Lead Acetate consumed per ton ore	0.331 lbs.	0.0042
Average value of pregnant solution	$4.038	$3.782

New Cornelia Copper Company.—The new leaching plant at Ajo was completed early in the year, and on May first the work of spreading the ores in the leaching tanks was commenced. The first shipment of electrolytic copper was made on June 18th, and the total since that time has been:

Electrolytic Copper	12,764,848 lb.
Cement Copper	3,316,283 lb.
Copper in shipping ore	3,401,060 lb.
Total	19,482,191 lb.

In addition to this there is 3,456,584 pounds of recoverable copper locked up in the process, including starting sheets, unfinished cathodes, solutions, and cement copper in launders. On the basis of copper shipped, the earnings were 19.5 cents per pound, and the expenses 15.8 cents. The difficulties experienced in starting the plant were not fundamental, and were easily overcome. The most serious was due to a lack of the proper number of launders for the precipitation of cement copper. The amount of iron and alumina dissolved from the leaching ores builds up in the solution, and it is necessary to continuously remove a large percentage of the returning low-copper electrolyte, replacing it with fresh acid and water. While additional precipitation launders were being built, the solutions became supersaturated and the extraction ran down from 80 per cent to as low as 65 per cent. In the future, steps will be taken to decrease largely the amount of copper recovered in the cementation tanks, since the latter costs two cents per pound more to make, and suffers a deduction of 3 per cent for smelting loss as well. The hard lead anodes which were possible sources of trouble in the electrolytic tanks show no serious corrosion after months of use. Two additional towers for the reduction of ferric salts by means of SO_2 gas have been constructed, which towers show an absorption of over 80 per cent. With this new equipment, it is thought possible to make a total production of over four million pounds of copper monthly, instead of the three million originally planned. During the year a favorable contract with the Minerals Separation Co. was signed, and a test plant will shortly be erected to devise the proper grinding equipment and a flow sheet for the sulphide ores. Mining operations in the oxidized zone will probably uncover in three years a sufficient quantity of sulphide ores to justify a flotation plant of 10,000 tons daily capacity.

The McKinley-Darragh-Savage Mines of Cobalt, Ltd.—This report calls attention to the fact that the average price for silver received was larger during the current year than previously, but this increase was more than offset by the added expense of labor and material, and the decreasing silver content of the ore. The general relation of production to costs and receipts for the past few years is clearly shown in the following table:

Year	Ounces recovered	Average Price Received	Total Costs	Net Profit
1912	2,717,383	$0.6166	$0.1859	$0.4307
1913	2,214,036	0.5919	0.2233	0.3686
1914	1,396,540	0.54385	0.31325	0.2306
1915	1,107,815	0.50785	0.2871	0.22075
1916	925,779	0.67364	0.4073	0.26634
1917	908,756	0.832	0.5709	0.2611

The total tons of ore treated in the mill amounted to 68,142, or an average of 197.56 tons per day. The average mill heads were 13.434 ounces silver per ton, tails, 1.795 ounces, giving an extraction of 87 per cent. During the year a mill was built to re-treat the accumulated tailings, which was fully equipped with the exception of the necessary grinding machinery. The mills were promised for delivery June 15, 1917, but had not yet arrived on Feb. 1, 1918.

Calumet and Arizona Mining Company.—In the reduction works at Douglas, Arizona, two blast furnaces operated a total of 689 furnace-days and smelted a total of 585,975 tons of ore. With an average of 13.3 furnaces operating in the roasting department, 451,255 wet tons of ore were reduced from 31.6 per cent sulphur to 10.2 per cent. The decreasing ratio between oxidized to sulphide ores tends to the reduction of the grade of matte, and greatly embarasses the converter department. A crushing department to operate on roaster charge is therefore in contemplation, which will enable the production of calcine containing about 6 per cent sulphur. Four reverberatory furnaces operated a total of 1419.2 furnace-days and smelted 420,458 tons of calcines, 62,871 tons of fettling, 27,173 tons of flue dust and 14,505 tons of flux. Additional waste heat boilers are to be installed, which will largely augment the excess power generated over that required to run the smelter, and which is now being transmitted to the mines in Bisbee, up to an eventual total of about 1700 kilowatts. The 200-ton acid plant started operation in March, and has operated successfully since the start. Five roasters deliver gases averaging 5.67 per cent SO_2 at a temperature of 840 deg. F. The total production has been 50,225 tons of 50 deg. Baumé acid, while the daily average since October first has been 223 tons.

Notable Meeting of the American Iron and Steel Institute

A NOTE of optimism dominated the fourteenth general meeting of the American Iron and Steel Institute in New York on May 31. At the annual banquet 1100 guests listened intently as Judge GARY, CHARLES M. SCHWAB and J. L. REPLOGLE told of the part the iron and steel industry is playing in the war. The audience was repeatedly roused to a high pitch of enthusiasm as the speakers expressed in patriotic terms the determination to win the war and obtain peace through victory.

JUDGE GARY'S ADDRESS

By way of emphasizing the fact that we must constantly look forward and not be concerned with the mistakes of the past, Judge GARY said:

"It would be useless to discuss what ought to have been done to prevent certain conditions. We are not at this time particularly concerned with the past. It would not be useful now to refer to the awful things that are being done in Europe, except for the purpose of emphasizing in the strongest words and in the best possible manner the fact that we personally are not without courage, we are not without vision, we are not without appreciation of our responsibilities.

"The steel industry is doing much to assist in carrying on this war. The American Iron & Steel Institute has been carrying on a very large work. It is in close communication with the Government officials all the time. It is a source of securing information and of distributing it to the Government officials. It is the agency upon which the Government depends very largely for its assistance in carrying on many of the activities essential to the war.

STEEL INDUSTRY IN GOVERNMENT FAVOR

"We find to-day Government officials in high places coming to the steel men with the statement that they want to co-operate with us, that they want our assistance; that they depend upon our loyalty and our ability to assist the Government in this time of great distress.

"It is to my mind a source of gratification that we may look forward to the future with hope and expectation that the Government of the United States is going to assist, to foster prosperity and business enterprise, instead of attacking it.

"We are doing another thing, gentlemen, and the Government is permitting us, assisting us, urging us to do it. We are day by day putting our affairs in better shape; we may not be making so much money, or if we do make it we may be paying it out in taxes and in extensions to our works for the benefit of the Government at such cost that we are absorbing our profits, but, nevertheless, we are putting our works in better condition; we are being better prepared for the future, the iron and steel industry will be on a better basis and a better footing than ever before; well prepared to succeed in the contest and the competition for international trade. If we win the war, that will be worth something to us, if we do not save much in cash. If we lose the war then it is not so important whether we have anything or not."

REPLOGLE PLEADS FOR EXTRA TONNAGE

J. L. REPLOGLE, director of steel supply, devoted his remarks mainly to the increasing war demand for iron and steel, and emphasized the necessity of producing an extra tonnage in those lines of steel products necessary to win the war. "War necessities is a rather flexible term," he said, "and it has been given much thought and consideration by those in authority at Washington."

"I had a conference Wednesday with the representative of the corset industry. It developed that their profits last year from this great industry aggregated $40,000,000, and that they require 15,000 to 20,000 tons of high carbon spring steel annually. I am no authority on corsets, but I must confess that after a complete discussion of the subject I was not prepared to dispute their claim that corsets were absolutely an essential.

"There have been many lists of so-called non-essential industries prepared at Washington, but they have never been officially issued, as there has never been complete agreement on this subject. All industries are essential from one standpoint or another—if no other, from the standpoint of the owner, and we have preferred to reverse the procedure and prepare a list of the more essential industries, giving them such preference in steel supply, fuel, transportation and labor as are necessary to get the results for which we are all striving.

"It may be surprising to many of you to learn that we now have unfilled orders on the books of the steel manufacturers and on our desks at Washington for 16,800,000 tons of steel for the United States and Allied Governments and the orders are coming in at a greater rate than they are being executed, although I believe we are near the peak of production. Difficulties of some of our gallant Allies are very great. Coal in Italy is $140 per ton, and its steel industries are working under great disadvantages. A very large per cent, probably 75 to 80, of the steel and coal in France is now either in the hands of our enemy or within the range of his guns. The requirements of our Allies will be enormous and the least we should do is all that we can do to give them steel when and as needed.

"The railroads of our country need more rails for safety and efficiency of operation, and it is difficult to give them any increase without restricting the production of projectile steel, which is largely rolled on rail mills. The forging plants are now getting under way, and have just reached the point where their consumption of projectile steel will be an extremely heavy factor. The shipyards have their ways built and many keels laid, and under the direction of Mr. Schwab will require vast tonnages of steel. His program for next year is at least double that of this year, and we must furnish him the steel to complete the great work he has to do and for which he is so well qualified."

SCHWAB SAYS ENCOURAGEMENT, NOT CRITICISM, NEEDED NOW

The hearty approval of the appointment of Mr. SCHWAB as director general of shipbuilding was voiced by the applause which greeted him as he rose to speak. He prefaced his remarks by saying that he was burdened with the great responsibility and with the

thought that the unmeasured confidence of his friends must not be disappointed.

"We all seek the encouragement and approbation of our fellowmen and I rejoice that because the great steel industry has given its approval of my selection, there has come greater enthusiasm and patriotism to men throughout the country which will mean much in winning this war; but, after all, no individual can be a very great factor. The undertaking is so vast that we must have the hearty support of every man, woman and child in the country. Some of us have been prone to criticise, but I should not be fair if I did not say that the work of Hurley, Piez, Goethals and others has been magnificent. When this country entered the war, all the shipyards were engaged in building ships for the navy and the yards for other ships had to be created. I have examined 65 to 70 per cent of the shipbuilding capacity of the country and I wish to say that the accomplishment is wonderful. What is needed now is not criticism, but encouragement.

"During May the United States finished and placed in commission 250,000 deadweight tons of ships. Every workday two such ships as that launched yesterday by the Submarine Boat Corporation were finished, and May will be the month of least production. I do not intend to indulge in prophecy, for that is dangerous, but I will say that you will not be disappointed. It is necessary that every industry connected directly or indirectly with shipbuilding shall be enlisted in the great work. So stupendous is the number of ships that the contracts for new works now aggregate $250,000,000. On the Great Lakes from 400,000 to 500,000 tons will be built this year, but that is not enough and capacity will be increased so that next year 1,000,000 deadweight tons will be produced. I am not worried about the steel, for I believe that it will be produced. The industry has more loyally come to the support of the Government than has the great steel industry. The shipbuilding capacity will be increased wherever necessary."

Technical Papers Presented

At the technical session the following papers were read:

The Electric Steel Plant at South Chicago, by T. W. Robinson. The Design of the Modern Blast Furnace Stack, by J. G. West, Jr. The Modern By-Product Coke Oven and Its By-Products, by W. H. Blauvelt. Effects of Phosphorus in Soft Acid and Basic Open Hearth Steels, by J. S. Unger. Conservation of Ferro-Manganese, by C. R. Ellicott. Relation of the Trade Papers to the Iron and Steel Industry, by Bertram S. Stevenson.

Manganese Price Scale

Schedule for Domestic Product Premiums and Penalties

THE War Industries Board has approved the scale of prices agreed to by the American Iron and Steel Institute. The following schedule gives domestic metallurgical manganese ore prices per unit of metallic manganese per ton of 2240 lb. for manganese ore produced and shipped from all points in the United States west of South Chicago, Ill. This schedule does not include chemical ores as used for dry batteries, etc. The prices are on the basis of delivery f.o.b. cars South Chicago, and are on the basis of all-rail shipments. When shipped to other destination than Chicago, the freight rate per gross ton from shipping point to South Chicago, Ill., is to be deducted to give the price f.o.b. shipping point.

For manganese ore produced in the United States and shipped from points in the United States east of South Chicago, 15c. per unit of metallic manganese per ton shall be added to above unit prices.

Above prices are based on ore containing: Not more than 8 per cent silica and not more than 0.25 per cent phosphorus, and are subject to:

Silica Premiums and Penalties: For each 1 per cent of silica under 8 per cent down to and including 5 per cent, premium at rate of 50c. per ton. Below 5 per cent silica, premium at rate of $1 per ton for each 1 per cent.

For each 1 per cent in excess of: 8 per cent and up to and including 15 per cent silica there shall be a penalty of 50c. per ton; for each 1 per cent in excess of 15 per cent and up to and including 20 per cent silica there shall be a penalty of 75c. per ton.

For ore containing in excess of 20 per cent silica, a limited tonnage can be used; but for each 1 per cent of silica in excess of 20 per cent., and up to and including 25 per cent. silica, there shall be a penalty of $1 per ton.

Ore containing over 25 per cent silica subject to acceptance or refusal at buyer's option, but if accepted shall be paid for at the above schedule with the penalty of $1 per ton for each extra unit of silica.

All premiums and penalties figured to fractions.

Phosphorus Penalty: For each 0.01 per cent in excess of 0.25 per cent phosphorus there shall be a penalty against unit price paid for manganese of ½c. per unit figured to fractions.

PRICES PER UNIT OF METALLIC MANGANESE FOR ORE CONTAINING WHEN DRIED AT 212 DEG. FAHR

	Per Unit
35 to 35 99 per cent, inclusive	$0 86
36 to 36 99 per cent, inclusive	90
37 to 37 99 per cent, inclusive	94
38 to 38 99 per cent, inclusive	98
39 to 39 99 per cent, inclusive	1 00
40 to 40 99 per cent, inclusive	1 02
41 to 41 99 per cent, inclusive	1 04
42 to 42 99 per cent, inclusive	1 06
43 to 43 99 per cent, inclusive	1 08
44 to 44 99 per cent, inclusive	1 10
45 to 45 99 per cent, inclusive	1 12
46 to 46 99 per cent, inclusive	1 14
47 to 47 99 per cent, inclusive	1 16
48 to 48 99 per cent, inclusive	1 18
49 to 49 99 per cent, inclusive	1 20
50 to 50 99 per cent, inclusive	1 22
51 to 51 99 per cent, inclusive	1 24
52 to 52 99 per cent, inclusive	1 26
53 to 53 99 per cent, inclusive	1 28
54 and over	1 30

In view of existing conditions, and for the purpose of stimulating production of domestic manganese ores, there will be no penalty for phosphorus so long as the ore shipped can be used to advantage by the buyer. The buyer reserves the right to penalize excess phosphorus as above by giving 60 days' notice to the shipper.

The above prices to be net to the producer; any expenses such as salary or commission to buyer's agent to be paid by the buyer.

Settlements to be based on analysis of ore sample dried at 212 deg. Fahr. The percentage of moisture in ore sample as taken to be deducted from the weight.

Rubber Substitutes

Factors and Limitations to Be Considered in Studying Rubber Substitutes—Extensive Use of Reclaimed Rubber and Mineral Rubber Decrease Demand for Oil Substitutes in This Country—Glue Substitutes Still Experimental

By ANDREW H. KING

STRICTLY speaking there is not, nor ever will be, a true rubber substitute. A substitute is something which may be used in place of another substance. It is therefore implied that a true rubber substitute would possess physical properties equivalent to rubber. The chemical properties are in most instances merely side issues. It is the valuable physical characteristics of rubber that are desired. These properties are not well known by the people in general, and even many men who work with rubber can not tell you why it is valuable. As a consequence, this field has been the playground for amateur inventors for over fifty years. Thousands of patents have been taken out and much valuable time, energy, and material spent in developing compositions, only to find them without any particular value. Each inventor applied the term "rubberlike" to his product, and thought he had made his fortune. Almost as many separate attempts are recorded in this field as in the pursuit of perpetual motion.

The reasons for this great amount of effort are simple to arrive at. First, rubber is valuable and a true substitute would undoubtedly bring the inventor a considerable sum of money. Second, very few if any of the investigators in this field had the least conception of the properties of rubber. Third, it is extremely easy to make preparations which to the uninitiated resemble rubber. As a result dabbling in rubber substitutes was formerly sort of an apprenticeship course for the amateur inventor.

A DEPOSIT OF GILSONITE

The Valuable Properties of Rubber

But what properties do make rubber a valuable material? Perhaps the most important is the extreme ease with which so many varied effects can be secured. Its adaptability is unrivaled. For example, one can obtain by suitable compounding from the same variety of rubber, stocks which will test as follows:

1. Tensile strength 3500 to 4000 lb. per sq.in. Stretch 2 in. to 14 in. (600%). — A tire-tread stock, very tough, resilient, not very hard.
2. Tensile strength 300 lb. per sq.in. Stretch 2 in. to 20 in. (900%). — A tire-tube stock, very stretchy; strong; will not tear readily.
3. Tensile strength 2000 lb. per sp.in. Stretch 2 in. to 22 in. (1000%). — An extremely soft and stretchy stock. Suitable for frictions.
4. Tensile strength 2200 lb. per sq.in. Stretch 2 in. to 10 in. (400%). — Very stiff, hard stock; resists wear; suitable for solid tires.
5. Tensile strength 6000 lb. per sq.in. Stretch zero. — A hard rubber.

The stretch may be varied from zero to 1000 per cent; the tensile strength from 1000 to 6000 lb. per sq.in.; the hardness may be anything from that of hard rubber to that of a soft, stretchy tube-stock. Many stocks, as for example the tread of a tire, are exceedingly tough and show great resistance to cutting and tearing. Tube-stocks are much more stretchy, but they also resist tearing to a marked extent. The addition of substitute to rubber decreases the tensile strength without greatly altering the stretch. The effect is dilution, and the more substitute present the weaker the stock.

Capacity for Absorbing Fillers

Another important property of rubber is its ability to take up and hold in solid solution large amounts of various inorganic and organic fillers. Crude rubber when properly manipulated will take up one-third of its own volume of fillers and still produce a product having desirable physical properties. Such a stock may have a tensile strength of 2800 lb. per sq.in., and a stretch of 500 per cent. The addition of a larger volume of filler is not desirable since from this point on tensile strength, etc., rapidly fall off. It is possible, however, to add to rubber up to one-half its volume of filler, but the product is of very little value. By volume of filler I mean true volume, weight divided by specific gravity, and not apparent volume. No substitute so far developed can even approach this record.

Under the head of substitutes I will take up not only the common oil substitutes known to the compounder as "subs," but various other related filling materials whether of an oily or asphaltic nature. These substances, while not true substitutes, do have certain valuable properties when used in the right way. Their general effect is to soften stocks which would otherwise be hard and stiff. Being of low gravity they tend to lower volume costs. Very often they are themselves sticky or tend to make the compound tacky. Consequently they find limited application in friction stocks. Certain of the asphalts and parafin tend to decrease porosity and permeability, and thus increase insulation.

The substitutes which have been proposed from time to time may be classed as follows:

1. Oil products, known to the compounder as subs
2. Asphaltic materials
3. Resinous substances
4. Greases
5. Waxes
6. Glue

Sub

Under this head may be placed those oil derivatives which are listed in market reports as "Rubber Substitutes." The methods of manufacture are as follows:

a. By addition of sulphur chloride to either the raw or blown oil.
b. By boiling the raw or blown oil with sulphur.
c. By heating and blowing with air, or adding nitric acid to the partly blown oil.

The oil substitutes come on the market in two principal classes, namely: white and brown (black). The first is prepared solely by means of sulphur chloride (method *a*), the second by methods *b* or *c*. The vegetable oil employed depends primarily on the market prices, the aim being to use the cheapest obtainable. These oils, as is well known, consist chiefly of glycerides of unsaturated fatty acids. Among vegetable oils the degree of saturation varies. The oil may be nondrying such as cottonseed, semi-drying such as rape or colza, or a drying oil like linseed. From any of these a good sub can be prepared by one or the other of the above mentioned methods. How wide the degree of saturation may vary is indicated in the following table of iodine values (Hehner).

Oil	Iodine Value
Linseed	170—200
Tung	150—170
Castor	82 — 90
Rape, Colza	92—109
Corn Oil	111—124
Poppy Seed	133—143
Cotton Seed	104—116
Olive	79— 90

Each maker of substitutes has his own procedure, and the value of his product depends primarily on how carefully he has attended to the details. White substitutes are chiefly chlorosulphides of fatty oils; brown (black) subs are either sulphides of fatty oils, oxides of triglycerides, or mixtures of the two.

1. Vegetable Oils

The following oils are the principal ones which find application:

Linseed, expressed from flax seeds.

Tung (China wood oil) obtained from the nuts of the tung tree.

Castor, secured from the castor bean.

Rape and colza are two oils from slightly different sources but have almost identical constants. They are obtained from plants grown extensively in Europe.

Corn is from the germ of Indian corn.

Poppy seed, expressed from the fruit of the poppy.

Cottonseed, expressed from cotton seeds.

Olive, expressed from olives.

(a) Addition of Sulphur Chloride

There is but little definite knowledge of what actually takes place when oils are treated with sulphur chloride, S_2Cl_2. The action is probably similar to the old vulcanization of rubber which produces an addition product $(C_{10}H_{16}S_2Cl_2)_x$. On adding sulphur chloride to a fatty oil a homogeneous mixture is obtained, which is followed rapidly by an energetic reaction accompanied by evolution of heat. Vapors of sulphur chloride, a little sulphur dioxide, and some hydrochloric acid are evolved. After a few minutes the mixture sets to a solid, yellowish white, rather elastic mass, which may be easily crushed in a mortar. On exposure to air any excess of sulphur chloride evaporates and a neutral substance is obtained. C. O. Weber[1] gives the following proportions of oil and sulphur chloride which he found satisfactory:

100	parts	linseed oil	with 30	parts	S_2Cl_2
"	"	poppy seed	" 35	"	"
"	"	colza, rape	" 25	"	"
"	"	cotton seed	" 45	"	"
"	"	olive	" 25	"	"
"	"	castor	" 20	"	"

There is evidently no relation between the drying power of an oil and the proportion of sulphur chloride it requires to form a solid substance. It has been found in practice that the high temperature resulting from the action of sulphur chloride on the oil is not desirable since it frequently causes carbonization. Consequently it is generally diluted with some solvent, such as light gasoline or carbon tetrachloride. It is also customary to cool the mixture, thus retarding the reaction. If the heat is removed as fast as produced one obtains a perfectly white substitute. The temperature range should not exceed 80 to 100 deg. C. An old recipe for dry white floating substitute is as follows:

15 kg. castor oil, 10 kg. rape, 5 kg. sulphur chloride in 1 kg. of light petroleum benzine.

The product is ground, spread in trays, and placed on racks to age. On alternate shelves are placed other trays of hydrated lime, which absorbs any sulphur chloride or hydrochloric acid that may be given off. Towards the end of the ageing period a small amount, never more than 5 per cent of magnesia is sometimes dusted over the sub to neutralise any remaining acid. The material is then ready to be sacked for shipment.

The above proportions of oil and sulphur chloride give an absolutely dry substitute. If a more greasy, or tacky one is desired, the quantity of sulphur chloride is lowered and the castor oil omitted. The recipe is now:

25 kg. rape, 1.3 kg. S_2Cl_2, 1 kg. light benzine.

The amount of sulphur chloride can be considerably reduced by using a brown oil. Thus blown cottonseed oil

requires only 20 per cent of its weight of sulphur chloride, while the raw oil requires 45 per cent.

(b) Heating with Sulphur

This method or some modification of it is most in use. The process consists essentially of heating an oil or mixture of oils to a rather high temperature, adding sulphur, and maintaining the heat for a certain length of time. The procedure is varied by the different manufacturers, but the following is a representative sample: 100 kg. of raw rape oil is heated in a boiler with 18 kg. sulphur to 160°-200° C. with constant stirring. The oil is first brought to the required temperature and the sulphur added. This may be in any form, provided it is free from acid, since all varieties melt at this temperature. The reaction is exothermic and once started the fire can be withdrawn. The end point is indicated by considerable foaming and rising in the kettle. The contents are then poured into pans to cool and congeal. At 145 to 155 deg. C. under pressure this sub flows like a viscous fluid. A much smaller amount of sulphur is necessary if the oil has been previously thickened by heating and blowing with air.

(c) Blowing With Air

The oil is heated in large open kettles to 160 deg. C. or above and air is blown through for some time. The speed with which it thickens up depends to a great extent on whether it is a drying or a non-drying oil. Thus linseed oil thickens up quickly but cottonseed requires a much longer time. China wood oil congeals in a very few minutes when merely heated to 250 deg. C. With the average oil mixtures the heating and blowing is continued until a small sample when cooled sets to a mass having the desired degree of toughness, elasticity, etc. In fact, this is the general procedure followed in all substitute experiments.

Sometimes the oxidation is catalysed by the addition of a small quantity of lead or manganese oxides. Lime or magnesia may also be used. The employment of lead or manganese oxides is not to be countenanced, because these substances bring about oxidation of the rubber, thus producing a poor ageing stock.

Addition of Nitric Acid to a Blown Oil

A very fine, light substitute is made in this manner. An example is as follows:

Nitric acid which has been diluted with twice its volume of water is added to a partly oxidized oil and the mixture boiled and blown until the reaction has gone as far as desired. On cooling the product is ground and washed well with water to remove all the acid. Just the right amount of acid must be added or the preparation will be spoiled.

With sulphur chloride one can obtain a nice, dry substitute, or a tacky one as desired. By suitable combination of blowing and addition of sulphur any degree of hardness, from a soft, sticky mess to an extremely hard, black resinous mass, can be produced. It matters little what oil the substitute is made from provided it is well prepared. It is frequently adulterated with paraffin, vaseline, or even mineral oil. A small quantity of paraffin is harmless, but mineral oils are certainly not. Free vegetable oil is much less destructive but is not particularly desirable. The free sulphur content must be known and allowed for in compounding the material. In order to cheapen their product some makers will add even as high as 20 per cent (by weight) of inert material such as barytes or aluminium flake. This is not often met with, however, since sub is always supposed to be of low gravity and is recommended for floating stocks. In general the ash should be very low. This merely insures the compounder that his sub is pure and he is getting value for his money. For obvious reasons the sub should contain no mineral acids and should not contain any ingredients which are liable to bring about spontaneous oxidation. In the end there is only one real test: that is actual trial. A new variety of sub should not be put into use until thorough age tests have been performed.

As previously stated, these substances are not in any sense real substitutes, and their true nature, which is that of fatty oils, is not altered by the vulcanization through which they have passed. They are still triglycerides, and therefore saponifiable. To this fact their limited use is due. They will not withstand high temperatures, steam, etc., and always decrease the strength of the rubber with which they are mixed. The sulphur content in white subs does not usually exceed 7 per cent. In the brown or black varieties it may vary from 3 to 20 per cent. Subs are insoluble in alcohol and acetone, and also insoluble in the usual rubber solvents but swell in them. Treatment with alcoholic potash always saponifies and dissolves them. About ten years ago every rubber laboratory kept a large bottle of this solution in stock solely for the examination of new substitutes.

Analytical: The first work on this subject was done by R. Henriques.[2] His results are often quoted and are still of value. They are given in Table I.

A_1 and B_1, from oxidized oil. C_2 from raw o'l.

[2] *Chem. Zeit.* 1893, 17, 634-638.

The determinations usually made are:

1. Acetone extract, which removes
   - (a) Unvulcanized oil
   - (b) Unsaponifiable matter, which includes
     - (1) Paraffin which is crystallized in the usual manner
     - (2) Mineral oil which is indicated by a flourescent extract
   - (c) Free sulphur.

   White sub contains from 1 to 2 per cent free sulphur. Over 3 per cent shows defective manufacture or reversion during storage.
2. Chlorine
3. Total sulphur
4. Acidity

   Dubosc states that there is always free acid, which is rarely in excess of 2 per cent. This is due to oleic acid. Dissolve in neutral alcohol and titrate. For mineral acid, which should be absent, extract with hot water and titrate.
5. Ash

   For brown sub 1 per cent is about the limit. In white subs a little lime or magnesia will usually be found. The latter should be in excess, since in the presence of a little oil it gives a non-deliquescent oxychloride. The presence of hygroscopic substances causes sub to decompose in storage.

$BaSO_4$	5 51	13 05			
MgO	2 19	1 10			
$CaCl_2$	0 27	0 08			

A, B, and C are white subs; D is black sub [illegible] rom [illegible]; E, is brown sub from rape oil.

Satisfactory samples of white sub will not show more than 15 per cent acetone extract and not over 5 per cent ash. Black and brown subs should not give over 25 per cent acetone extract nor ash higher than 3 per cent. Mineral acid should be absent in all cases.

In Europe substitutes are used much more extensively than in this country. American manufacturers, particularly tire companies, have not taken kindly to them. They hold that employment of sub is not only risky but productive of rather poor results. Another factor in this country is the huge supply of first-rate reclaimed rubbers many of which are of low sp. gr. No sensible manufacturer needs to use sub merely because he must cheapen this or that compound. He will use shoddy and produce, for the money, a higher quality stock than he could with sub. In Europe they formerly were not as successful with reclaiming practice and had to resort to substitutes, which they developed to a high degree.

2.– Asphaltic Materials

Under this head we will consider the following:

a. Coal Tar
b. Coal Tar Pitches
c. Asphalt Pitches
d. Mineral Rubber

Coal Tar

Coal tar, as such, finds a limited application, chiefly in reclaiming and in the compounding of exceedingly dry and hard shoddies. The amount used will never be more than 5 per cent but is usually 2 or 3 per cent based on the finished stock. It softens a stock and makes it more easily worked, for example, in a tube machine. The medium grade of tar which serves very well is about as thick as corn syrup, remains fluid as low as 10 deg. C. and should lose not more than 5 per cent when heated for 1 hr. at 100 deg. C. As indicated, it is only employed in very poor stocks for mechanical goods, as for example, stair pads, cheap heels, novelties, and cheap frictions.

Coal Tar and Asphalt Pitches

These two varieties of pitches, while coming from different sources, are very similar in their physical properties and use. Coal tar pitch is obtained by the distillation of coal tar and is marketed in many different grades which vary both in hardness and in melting point. Depending on the severity of the treatment it may vary from 37.5 deg. C. to 174 deg. C., and the constitution from a thick tar to a very hard, resinous mass. A piece of it may be easily chewed without any crumbling. Asphalt pitch may be either purified natural asphalt or the still residue from the distillation of asphalt base oils.

Both asphalt and coal tar pitches contain some mineral oil, and consequently their use beyond certain limits is dangerous because of the disintegrating action. The melting point varies from 100 to 130 deg. C. When added to rubber on the mills they soften and are easily dissolved. They make a batch soft, easily worked, and somewhat sticky. As a consequence they are much used in mechanicals for softening stocks which are to be run on a tubing machine, for frictions, and in cheap molded goods in which they function to a certain extent as binders. The quantity added will vary with conditions, but as a rule must not be greater than 15 per cent, otherwise there will be serious difficulty in milling the

stock which will stick to the rolls and be extremely hard to cut off. Eight to 10 per cent is the usual figure.

These pitches are soluble in benzole, carbon bisulfide, chloroform, carbon tetrachloride, about 50 per cent soluble in acetone, and about 70 per cent in naptha. The sulphur content may vary from 0 to 5 per cent, but is usually around 2 per cent or lower. Free carbon is much more important. It is liable to vary from 5 to 25 per cent but should be absent.

(d) Mineral Rubber

It is perhaps stretching a point to class coal tar and the pitches as rubber substitutes. Yet there is a good economic reason for it. If by means of certain pitches and the cheapest possible reclaim one can make a satisfactory stair tread, then there is certainly no reason for using fine para and high priced compounding materials. The policy is to suit the product to the purpose. But mineral rubber commonly known as MR is different. Coal tar and the pitches find their widest application in cheap mechanicals. MR can be used in all the high grade stocks except those which must be very white in color. It is by far the best substitute ever brought out. Stocks which must withstand the more severe conditions are actually benefited by the substitution of a small percentage of rubber by MR. That its merits are appreciated by the rubber trade is shown by its rise in price. In 1913 a good grade could be obtained for 1c per lb. By 1915 it was 2c and now it costs about 5c. When one considers that it is made from practically a waste material the rise in price is clearly due to the demand.

Mineral rubber, MR, is a hard, black, resin-like substance which readily passes into solid solution when added to rubber on the mixing rolls. The melting point by the cube method varies from 160-185 deg. C. When added on the mill, the heat of the rolls and the rubber (20 to 70 deg. C.) combined with the mastication it receives, softens it to the point where it is readily taken up and homogeneously distributed throughout the mass. When handled on a factory scale it is impossible to add more than 35 lb. of MR to a 100-lb. batch. The rubber absorbs it but becomes so soft and tacky that it cannot be cut off the mill. In regular practice 20 per cent is about the limit. More than this makes milling so difficult that the stock is likely to be overworked. In high grade stocks not more than 10 per cent should be used because of certain properties which will be discussed later. MR is essentially a bitumen. The first preparations were made by carefully combining gilsonite or grahamite with purified natural asphalt to give the desired physical properties. The next step in the development was to blend gilsonite or related bitumens with coal tar or asphaltic pitches. Following this, certain enterprising manufacturers discovered that they could produce an apparently good MR by cooking and blowing for a long time still residues of asphalt pitch. Today, much MR is made in this way and only two or three firms actually use any gilsonite. The processes in vogue are largely secret, but enough of the general procedure is known to realize that the operation is extremely simple. The important points are the selection of materials and the proportions in which they are combined, which must be learned by experiment. In order that the problems which confront both the maker and user of MR the nature and origin of bitumens will now be briefly discussed.

Asphalt: According to Engler the asphalts are derived from petroleum hydrocarbons through polymerization, free oxygen acting as a catalyser of the change. It has been shown that the formation of asphalt takes place more readily in the presence of air, yet the amount of oxygen absorbed is too small to account for the formation as oxidation.

The principal source of natural asphalt is Trinidad lake, which contains apparently an unlimited supply. According to Richardson[3] crude Trinidad asphalt contains 28 to 30 per cent water. In the dry state it has 56 per cent bitumen and 38 per cent mineral components. The remaining 6 per cent is water of hydration of the clay and some insoluble organic matter. The pure bitumen softens at 76 deg. C., melts at 83 deg. C., sp. gr. 1.032 at 25 deg. C., and contains 82.33 per cent carbon, 10.69 per cent hydrogen, 6.16 per cent sulphur, and .81 per cent nitrogen. It contains 63 per cent naphtha soluble malthenes of great viscosity and gummy consistency. The remainder is chiefly very hard and brittle asphaltenes. The Trinidad asphalt is mined with pick-axes, and somewhat purified by melting. Unless this is done very carefully by steam a part of the asphalt will be destroyed by overheating thus producing free carbon, which is contained by the poorer grades in amounts up to 11 per cent.

When this asphalt is to be used for paving no attempt is made to separate the high mineral content which is really valuable for this purpose. The molten asphalt is poured through a wide-mesh screen (1 cm.) to remove sticks and large stones. To completely purify it for use with rubber is rather expensive. Settling operations will do much, but the best way is by use of solvents, thinning the solution, settling, decanting, and filtering. The pure solution is then concentrated by evaporation and the solvent removed.

Residuum asphalts (artificial asphalts) are made from the still residues when asphalt base oils, such as those from Mexico, Texas, or California are distilled. With Pennsylvania, straight chain, oils paraffin is the end product, but with these oils, cyclic, asphalt is obtained. The asphaltic residue is then further treated by long cooking, during which air is passed through the melt. Artificial asphalt is really an accelerated natural asphalt. The nature of the product is dependent on

1. The duration of the cooking period. 2. The temperature. 3. Amount of air passed.

The product may be very soft or very hard, depending on the conditions.

Properties of Asphalts: They (both natural and artificial) are almost entirely soluble in carbon bisulphide and carbon tetrachloride; about 70 per cent soluble in 86 deg. B. naphtha; about 75 per cent soluble in ethyl ether; fixed carbon 0 to 15 per cent; melting points lay between 55 and 100 deg. C; loss on heating 5 hr. at 163 deg. varied from zero to 5 per cent. Sp. gr. at 15 deg. C. about 1.04; sulphur from .5 to 4 per cent. The asphalts consist to a very considerable extent of hydrocarbons not acted upon by sulphuric acid, that is, saturated hydrocarbons. Gilsonite on the other hand contains but a very small amount of such components.

[3]Petrol 7,1347

Data concerning this has been published by Richardson, as shown in table VI.

TABLE VI.

	Sp. Gr.	Per Cent Solution in Naphtha	Per Cent Saturated Hydrocarbons
Petroleum flux (Texas)	0 956	97 5	72 8
Residual pitch	1 089	65 0	33 1
Bermuda asphalt	1 082	62 2	24 4
Gilsonite (Utah)	1 044	47 7	5 5
Grahamite (Okla.)	1 171	0 4	0 3

Gilsonite and Grahamite: Grahamite is the result of metamorphic changes in gilsonite, which was in turn produced by metamorphic action on petroleum. The two materials present varying degrees of condensation, from the softest gilsonite which will flow in the sun to the hardest and most brittle grahamite which will not melt even at high temperatures.

The changes as metamorphism proceeds are indicated by the gradual decrease of the hydrocarbons and their derivatives which are soluble in naptha, from the amount present in the softest gilsonite to that in the hardest grahamite with a corresponding increase in the coke yielded by ignition. In Table VII we have data set forth by Richardson in illustration of this point:

TABLE VII.

Source	Flow of	Sp. Gr	Per Cent Solution in Naphtha	Per Cent Residual Coke
Residual:				
Texas residual petroleum		0.9524	88 0	6 5
Gilsonites:				
1. Utah softest	285	1 011	55 5	10 0
2. Utah		1 037	46 9	12.3
3. Utah	260		47 2	12.8
4. Utah	345	1.037	46 1	13.9
5. Utah hardest	Intumesces	1.057	24 5	16.7
Grahamites:				
Cuba, Bahia	Intumesces	1 157	38 8	40 0
Trinidad	Intumesces	1.156	14 8	40 0
West Virginia	Intumesces	1.130	9 4	36 8
Colorado	Intumesces	1 160	0 8	47 4
Oklahoma	Intumesces	1.184	0 4	51 4

Depending on the environment, petroleum was converted by metamorphic action into either gilsonite or natural asphalt. Grahamite, as previously mentioned, is derived from gilsonite, which is found chiefly in Mexico, Utah, California, Colorada, and at certan places in the Appalachian mountains. Grahamite is more abundant than gilsonite and is found in the same regions, in the southwest, etc.

Plasticity and Elasticity

Rubber has two important properties, plasticity and elasticity. Before vulcanization it is highly plastic with but little elasticity. After vulcanization it is highly elastic and very slightly plastic. MR is essentially a plastic substance and its introduction increases the plasticity of the resulting stock. This is not a desirable feature since it leads to a high set which may be explained as follows: If a thin piece of tube stock be cut and marked say with marks 2 in. apart and the piece stretched until the marks are 18 in. apart, then released; the distance between the marks will now be found to be greater than 2 in. This excess is known as set and depends on the plasticity of the rubber. The same thing is illustrated by the behavior of a pair of cheap overshoes. They fit well the first few times they are worn, but later develop a set. We say that they have stretched and no longer grip the shoes but slop up and down. This is entirely due to the plasticity of the stock of which the overshoes are made. Plasticity is the principal difficulty with MR. It is a valuable compounding ingredient. It decreases porosity and renders a stock easily worked. It may be substituted for a small per cent of the rubber content but its use is limited by the plasticity it develops in the stock. For high grade compounds not more than 10 per cent is desirable. In certain cheaper stocks such as mechanicals it may be added up to as much as 20 per cent. Used in small quantities it has little effect on the tensile strength and stretch, but as it is increased the set also increases. With larger amounts the physical properties are lowered. The effect when used in excess is to make a tough, snappy stock soft and dead feeling. To prevent confusion it should be mentioned that only a small percentage of rubber may be substituted by MR, never more than 4 per cent in a batch high in rubber, but it may be added to such a stock in much higher percentages in which case it functions as a light gravity filler.

The inspection of MR is extremely difficult. About the only test which is of value is melting point which is best made by the standard cube method. Much depends on the integrity of the manufacturer, and his ability to duplicate his first shipment, which should be given a thorough trial in several stocks and its ageing properties investigated.

As mentioned before, gilsonite is highly unsaturated, consequently MR's containing it are able to unite with sulphur when vulcanized. As a consequence only about one-half the MR added to the stock can be removed by acetone and chloroform extractions. The remainder is insoluble in the solvents ordinarily used in rubber analysis and consequently render a correct determination of the rubber content impossible. For this reason certain specification and analysis committees refuse to admit its use. The policy is rather a left handed one since MR really has certain desirable effects.

Vulcanization with sulphur seems to alter the nature of MR. A sample of MR rubber which contained gilsonite was examined by the writer not long ago. It was entirely soluble in chloroform and about 30 per cent soluble in acetone. A batch was made up containing 20 per cent. On extracting the cured stock 55 per cent of the MR was soluble in acetone, 5 per cent in chloroform, and the rest (40 per cent) insoluble in any solvent which would not attack rubber.

Resinous Substances

In this class are rosin oil, rosin, pitches, and crude turpentine. Their general effect is to soften and render tacky the stocks in which they are mixed. Rosin oil does not age well and should be used with great caution. Representative of the rosin pitches is Oregon balsam, which consists of rosin in turpentine. It is very sticky, and is sometimes used in quantities up to 1 per cent in high grade compounds which are to make good union with other stocks. It is also used in quantities as high as 5 per cent with cheap shoddies, where it acts to a certain extent as a binder. Crude turpentine which is true crude turpentine with the volatile oil removed is used for the same purpose, but is not as efficacious.

Greases and Waxes

Palm oil has long been used as a dope for softening stocks which do not flow smoothly on a calender. Vaseline is employed for somewhat the same purpose but is added directly to the batches during milling. The chief

waxes are Japan and paraffin. The former is really a grease and behaves as one. Paraffin is used quite a little in insulation. It is restricted in other work by the fact that when present over 2 per cent it comes to the surface and produces a dirty white scum.

Glue

There is hardly a rubber chemist who at some time or other has not played with this substance and the interesting combinations which can be prepared by mixing it with glycerine. Glue, glycerine, and vinegar are still used at times for multicopy pads and printer's rollers. But such articles are not strong and are hygroscopic. Many chemists have attempted to make something out of the insoluble product which results when glue is treated with potassium dichromate and alum or with formaldehyde. Many such ideas are patented but none have had any great success. Not long ago an English patent was granted for the manufacture of cheap tubing. The glue glycerine gel was to be fed through a die as in ordinary tube machine practice; the tube dropping directly into a solution of formaldehyde. There is no question that such a tube could be made, but it would have very little strength. Glue glycerine preparations do not work well with rubber. The behavior is similar to an attempt to mix water and oil.

Summary

In the foregoing the writer has pointed out certain factors and limitations which must be considered in studying the rubber substitute situation. Briefly they may be summarized as follows:

1. There is no real substitute for rubber.
2. Oil substitutes are not in great demand in this country because of the extensive use of reclaimed rubber and MR.
3. Certain pitches, greases, and waxes have been mentioned and their principal use stated.
4. Glue substitutes are yet in the experimental stage.

American Chemists' Defensive Measures Against Gas Attacks in France

The Gas Service a Special Arm of the American Expeditionary Forces—Enemy Now Sends Over Gas in Shells, Bombs, Clouds and Hand Grenades—Trenches and Dugouts Must Be Cleared After Attack

By ROBERT K. TOMLIN, Jr.
Special editorial representative in France for the McGraw-Hill engineering publications.

After one has been in France for some time and has had an opportunity of observing the varied character of the operations conducted under the general direction of the Chief Engineer of the American Expeditionary Forces, he begins to realize to what extent warfare on the vast scale of the present day is making insistent and continuous demands upon technical specialists. In previous articles in the McGraw-Hill engineering publications I have referred to a few of the almost infinite varieties of specialized work which our engineers are handling—road-building, railway yards, water terminals, quarrying of rock, light railway construction and operation, water supply at the front, map-making and the interpretation of aerial photographs. To these must be added the activities of our engineers and chemists in the gas service.

The men attached to this branch of the Chief Engineer's department are busy both in the field and in the laboratory. Their efforts, as explained to me at our General Headquarters recently by Col. F——, chief of the Gas Service, A.E.F. are being conducted along two major lines—offense and defense. On the matter of our offensive work it is considered advisable to say nothing at the present time. However, certain generalties regarding the German gas attacks and our defensive measures may be permitted, for most of what follows is pretty much of an old story here, although some of it may not be so well known on the other side of the Atlantic.

Few Cloud Gas Attacks Now

There has been for some time past, according to the Chief of the Gas Service, a very general trend away from the cloud gas attack on the part of the Germans. Practically all of the gas now comes over in the form of shells, fired either by long-range artillery pieces, or by trench mortars. There are a number of reasons to account for this change from the original form of attack. In the first place, the prevailing winds on the front have been against our enemy about 75 per cent. of the time. In the second, a comparatively light gas must be used in a cloud attack—a mixture generally of chlorine and phosgene—which is less effective than the heavier "mustard" gas used in shells. Then, too, the wind must be just right before a cloud attack can be launched, and the preparations for the attack in this form are necessarily elaborate, time-consuming, and hazardous, due to the danger of having gas containers punctured by rifle bullets or shells while in transit toward the front-line trenches. The effects of a light gas put over in a cloud are much less permanent than those of the heavy mustard gas.

In the days of the cloud attack, cylinders containing the liquefied gas were spaced along the front-line trenches at intervals so that there was available about 25 or 30 lb. of liquefied gas per foot of front. From these tanks pipe-lines of rubber composition or lead were extended over the parapet and forward a short distance. When the valves were opened it was generally the enemy's practice to begin a violent machine-gun fire to mask the hissing sound of the escaping gas. It is said that the Germans, in the early days of gas attack, started to build some distance behind their front a big manufac-

facturing plant and holder from which gas was to be piped underground to various points of use on the front lines. Allied aviators and artillery, however, by effective bombing and shelling, put a quietus on the central gas plant project.

Wind Velocities

Gas clouds have been launched by the Germans with a wind velocity as low as 2 miles per hour. Four miles per hour is considered fairly safe for the attacking party, but the most effective work can be done with the wind blowing at from 5 to 8 miles per hour. Gas attacks have been made on fronts varying from 1 to 5 miles. Even as far back as 12 miles from the front their effects have been great enough to demand the wearing of masks. The lightest gases used in clouds did not can do damage 10 or 12 miles back of its initial point of discharge.

Being heavier than air the gas will follow the slope of the ground and, if atmospheric conditions are favorable, will sweep down a valley like the flow of a river. The effects of gas are generally confined to points not higher than 30 feet above the general level of the ground. A gas cloud passing down a valley may, therefore, be largely avoided if there are any high points, such as knolls, which can be climbed. Rain or mist has no appreciable influence on the effectiveness of a gas cloud attack.

Gas Shells

When the use of gas in shells was first tried the enemy used just enough explosive to vaporize the charge

AMERICAN SOLDIERS WEARING NEW GAS MASKS IN FRANCE
Copyright by Committee on Public Information

produce an effect which lasted more than about 20 minutes; that is, with a 4-mile wind and a mixture of phosgene and chlorine, the all-clear signal could be given half an hour after the cloud had passed over a specific point in the open near the Front, but in dugouts there was danger during a period of 3 hours or more, unless a fire could be built inside to ventilate them, in which case the air became safe to breathe in 15 or 20 minutes. The cloud attack was sometimes launched in one continuous operation and at other times in waves, with a half hour or even greater interval between successive clouds. In answer to a question regarding the lateral spread of a gas cloud, the Chief of the Gas Service explained that with a low wind velocity and a high concentration of light gas, the edges of the advancing cloud would become too dilute to do much damage before the cloud attained twice its original width. If launched on a wide front, however, a gas cloud of high concentration of liquefied gas. Several different kinds of gas were employed in the early days of gas shelling before the use of "mustard gas" became prevalent. The noise of the detonation of these lightly charged shells was much less than that of a high explosive shell and it was easy to differentiate between the two. Sometimes, in fact, the low explosive gas shells were mistaken for "duds" (shells which fail to explode properly). Now, however, the amount of the explosive charge in gas shells is being increased, so that almost every bursting shell must be regarded with suspicion so far as gas is concerned.

"Mustard gas," which has been used by the enemy so extensively for months past, is an organic compound containing chlorine and sulphur, known as dichlorethylsulphide. It is employed in shells of all calibers up to 8-in. It produces severe burns if it comes in contact with the body and is painful to the

eyes. Food eaten after having been subjected to the influence of mustard gas has been known to burn the lining of the stomach. It is a very heavy gas and has a fairly high boiling point, 400 deg. Fahr., a fact that makes it unsuitable for cloud attack, for it must be vaporized by an explosion. Gas has killed men as far back at 12 miles from the front. Mustard gas will linger a long time in the vicinity of shrubbery and woods and, forming pockets in shell craters, contaminates the earth, which often must be treated with chloride of lime if there is any chance of men coming in contact with it. With a favoring wind a mustard gas shell can be shot over troops and dropped only 500 yd. ahead of them without placing them in danger.

Gas Specialists Instruct Troops

One of the functions of the Gas Service of the American Forces, so far as defensive work is concerned, is to equip our troops with the means of combating gas attacks and to instruct them in safety measures. With this object in view men specially trained in gas work are assigned to the various units in the field and act as instructors in all matters relating to defense against this form of attack. For the guidance of officers the Gas Service has given much valuable advice on the detection of gas and what to do in case of attack.

Nowadays gas-shell bombardment is to be expected everywhere within the range of artillery—in front line trenches, communication trenches, camps, billets, etc. The enemy's object, of course, is to catch bodies of men unprotected against gas and to develop a high concentration by heavy bombardment. The practice now is either to mix up the gas and the high-explosive shells, or to use gas shells containing a fairly large charge of explosive. This makes it very difficult to detect the beginning of a gas bombardment, especially as the mustard gas has a very slight odor and does not produce an immediate effect on the eyes and lungs. After several hours, however, it causes the eyelids to swell, results in intense pain and loss of sight for from one to four weeks, and, if inhaled, its attack on the lungs soon produces death.

Two Forms of Mask

The instructors from the Gas Service train our line officers in the proper use of the gas-mask and box-respirator, and this instruction is passed on by the latter to the men in the ranks. The so-called mask is the one used by the French armies and is a face-covering with a pocket containing chemicals through which the breath is drawn and expelled. With the mask one breathes through the nose. The box-respirator, the standard for the English armies, is a more elaborate affair, comprising a face-covering, nose-clip, chemical box with check valves and a flexible tube extending from the chemical box into the mouth, the teeth closing on a rubber strip something like that of a foot-ball nose-guard. Breathing must be done through the mouth, as the nostrils are closed by the spring-clip. The box-respirator is considered the more reliable of the two forms of equipment. It proved to be well adapted to our white troops, but when our negro regiments attempted to use it they found the standard clip entirely unsuited for their broad, flat noses. A detail of the Gas Service, therefore, was assigned the job of designing a special nose-clip for negroes.

In the American Forces a box-respirator or a mask must be carried within 12 miles of the front; the choice is optional. But regulations prescribe that the box-respirator must be worn within the 5-mile zone and that

Copyright by Committee on Public Information

U. S. MARINES IN FRANCE TRAINING WITH FRENCH MASKS, ENTERING A GAS LADEN CHAMBER
Copyright by Committee on Public Information

a man must be clean-shaven, for a heavy growth of beard prevents close contact between the skin and the face-piece, thus allowing gas to leak in. Within the 2-mile zone, the mask and box-respirator must be worn, the latter in the "alert" position—flap open.

Protection of Dugouts

Since all gas used in attack is heavier than air it collects in low spots, such as dugouts and cellars, unless these are protected. Our gas specialists have outlined the best methods of such protection. In the case of a dugout the entrance is to be covered with blankets nailed across the top of the doorway and attached along the bottom edge to a 1-in. x 3-in. plank upon which the blanket may be rolled up. Sometimes these blanket stops are single and sometimes in pairs, the latter forming a sort of entrance lock to the dugout. When the gas warning is sounded these blankets are unrolled and sprayed with water or a mixture of glycerine and water to ensure air tightness.

After a gas attack trenches and dugouts must be cleared. For the trenches a canvas anti-gas "fan," which has the general form of a small snow-shovel, has been devised. It has a short wooden handle and the canvas blade is braced with cane strips; the end and sides of the shovel blade are in the form of hinged strips, the latter making contact with the sides of a trench. With this fan, gas which has collected in a trench is literally shoveled out. The fan is first brought down with a slapping motion and then flicked upward over the right shoulder of the man who is operating it, gas being thrown up over the parapet.

In clearing dugouts ventilation resulting from the building of a fire within them is considered the best method. In general 1 lb. of dry wood per 100 cu.ft. of air space is sufficient. The fire should be kept burning at least 15 minutes. There are also special mechanical fans with filter bottoms for clearing dugouts.

Among other duties connected with the defense against gas are wind observations, at regular intervals, and the collection of samples of gas during an attack. The field work, however, represents only part of the operations of the Gas Service. A staff of chemists is engaged in the laboratory work necessary for the investigation of the countless problems involved.

Paris, France.

France Needs Agricultural Chemicals

According to Vice Consul A. D. Beeler of Bordeaux the proper care of the vineyards requires the application many times during the season of certain solutions of chemicals which have been employed widely for a number of years. These chemicals include copper sulphate crystals, sulphate of iron, sulphur of both triturate and sublimate forms free from sulphuric acid and various special fertilizers for the soils. Some cultivators apply first the sulphate of iron in March as a preliminary measure against the diseases of the vine and in order to clean the stalks. The next application is usually a wash of sulphur, which remains on the vines until after the leafing period, late in April, when the spraying with solutions of sulphate of copper is begun. With the growth of the foliage come new dangers in the nature of diseases, mildew, brack rot, scale, and caterpillars, all of which increase the necessity for the continued spraying of this solution of copper sulphate throughout the growing season until a very short time before the harvests or vintages in late September or early October. Local manufacturers are unable to supply the demand owing to their activities in making munitions, while importation from England is inadequate to supply the deficiency and sulphur importations from Italy are largely curtailed. Copper sulphate crystals are therefore selling in the local markets at from 18 to 21 cents per pound, and the available sulphur supply at from 11 to 13 cents per pound, prices never before known in that region. Under these conditions, it is thought that a large quantity of American chemicals could be profitably exported. The present tariff per 100 lb. is 26c. for $CuSO_4$; 11c. for $FeSO_4$; 26c. for sulphur.

Italian Chemical Manufacturing.—Many chemical manufacturing concerns have been started in Italy since the war. The most noteworthy of these installations are the Solvay soda works at Castiglioncello, and Piedimulera, the explosive plants centering around Cengio, and the ammonia and nitric acid plants at Legnano. In many places the distillation of tar and the production of benzol is under way, while various Italian factories have begun making sulphur dyes and pharmaceuticals.—*Commerce Reports.*

Analysis of Natural Gases*

THE analysis of natural gas by the methods given for the other fuel gases described herein is not very satisfactory. If but little, say 10 cc., of the methane and ethane are exploded with oxygen, any error in reading is multiplied many times. Again on combustion of a large quantity with oxygen, the resultant gas is nearly pure carbon dioxide and, its solubility in water varying with its percentage, consequently a relatively large quantity is dissolved. The second contraction, i.e., on absorption of carbon dioxide, being low, the result is that the sum of the methane and ethane obtained by calculation is over 100, and the nitrogen a minus quantity. To overcome these defects, use is made of the following method in which the contraction on explosion and on absorption of the carbon dioxide is treated as one known factor and the oxygen entering into combination the other factor.

Percentage of Oxygen in Commercial Oxygen

Commercially pure oxygen is used instead of the oxygen and nitrogen mixture of previous methods. This practice is necessary on account of the great amount of oxygen required for combustion. The determination of the percentage of oxygen is made by exploding a large quantity of it with hydrogen and noting the resultant contraction, of which one-third equals the oxygen. The determination is best accomplished in the following manner: about 100 cc. of pure hydrogen are forced into the burette, the capillary is filled with water from the explosion pipette, a reading is taken, and the gas is forced into the explosion pipette until the water level is at zero; about 100 cc. more hydrogen are introduced, and a reading is taken; the gas is then forced into the explosion pipette until the water level is again at zero. About 60-65 cc. oxygen are then added, a reading is taken, and 15 cc. portions are successively introduced into the explosion pipette and exploded, the gases being well mixed before the last explosion. After the final explosion, the residue is drawn over, the capillary being filled with water, and a reading is taken. One-third of the contraction is oxygen, from which the percentage can be calculated.

Determination of Carbon Dioxide

Exactly 100 cc. are forced into the burette from the sampling tube, as described previously. A reading is taken, and the gas is passed through the potassium hydroxide pipette for the absorption of carbon dioxide, then returned to the burette, and the capillary filled with water from the explosion pipette. A reading is taken; the contraction in volume is the percentage of carbon dioxide.

Determination of Illuminants

The use of fuming sulphuric acid is not advisable here as it absorbs the higher members of the paraffine group. In its place is substituted a pipette containing a 1 per cent solution of palladium chloride. The gas is passed three times through this solution and returned to the burette, the contraction being illuminants, thylene and its homologues. The contraction in volume would also include hydrogen and carbon monoxide, if present; however, the rate of absorption of these gases is comparatively slow. They are generally absent, and their absence is proved by the method described later. One passage of natural gas through fuming sulphuric acid gives about the same contraction as the method described herein, but repeated passages take out more and more of the paraffine. No definite result is obtained.

Determination of Oxygen

After absorption of illuminants, the gas is passed into the phosphorus pipette for the absorption of oxygen, and while it is there, the requisite amount of oxygen is measured in the burette and transferred to the explosion pipette. The gas in the phosphorus pipette is then returned to the burette, and the contraction due to absorption of oxygen is noted.

Determination of Methane and Ethane

The gas residue consists, besides the small quantity of nitrogen, of methane, ethane and perhaps other higher homologues. It is impossible by any method to determine more than two gases of the paraffine group by combustion, and the gases are assumed to consist of methane and ethane. No error is introduced by this assumption, as proven later.

While the gas is in the phosphorus pipette as described above, oxygen is drawn into the burette to its capacity, the capillary is filled with water, and a reading is taken. The gas is then forced into the explosion pipette until the water is at the zero mark, the capillary containing gas. The right hand capillary tube is flushed with water, and 50 cc. of air are drawn into the burette and measured; about 15 cc. oxygen (sufficient to make the total 122 cc.) are then added, and the gas is forced into the explosion pipette. The right hand capillary is flushed out, and the gas in the phosphorus pipette is drawn into the burette and measured, as described under Determination of Oxygen. One-half the residue is discarded or reserved in the phosphorus pipette. About 10 cc. of the half reserved for analysis are forced into the explosion pipette and exploded. This operation is repeated with successive portions of the gas until the last is added, when the gases are thoroughly mixed before explosion. The resultant gas is very rich in carbon dioxide, which, if the gas were passed into the burette, might be absorbed by the water. Later on this dissolved carbon dioxide may be given off by the water. Therefore, a compressor is placed on the rubber tubing from the burette to the bottle, and the gas in the explosion pipette is forced to bubble through the potassium hydroxide pipette by raising the bottle connected to the explosion pipette. After the gas has been passed several times it is transferred to the burette, and a reading is taken. The sum of the diluted oxygen added and the gas residue taken for explosion, minus the volume remaining after the absorption of carbon dioxide, is Contraction "A." Hydrogen is then added to the capacity of the burette, a reading is taken, and the gases are passed into the explosion pipette, well mixed and exploded. The residue is passed into the burette and measured; the decrease in volume is Contraction "C."

From the above contractions ("A" and "C") and from

*From the second edition of the U. S. Steel Coproration's "Methods for the Technical Sampling and Analysis of Gases."

a knowledge of the amount of oxygen in the commercial oxygen, the methane and ethane may be calculated. The reactions of burning methane and ethane are as follows:

$$CH_4 + 2O_2 = CO_2 + 2H_2O.$$
$$2C_2H_6 + 7O_2 = 4CO_2 + 6H_2O$$

From these reactions it is seen that the total contraction on combustion and absorption of methane and ethane are 3 and 9 2 times the volume of the respective gases; or that "A" = $3CH_4 + 9\ 2C_2H_6$. Likewise the oxygen consumed (Oc) is 2 and 7 2 times the volume of the respective gases; or Oc = $2CH_4 + 7\ 2C_2H_6$. Also it is evident that the oxygen consumed equals the oxygen added (Oa) minus the oxygen entering the second explosion, which is 1 C. or Oc = 1 3C.

From these equations the following formulæ are derived:

$$CH_4 = \tfrac{2}{3}\ A + C - 3Oa.$$
$$C_2H_6 = (A + 1\ 3C - 0a) - CH_4.$$

DETERMINATION OF HYDROGEN AND CARBON MONOXIDE

These gases are generally absent. If present, they reduce palladium chloride somewhat slowly, water and carbon dioxide being formed. If the diminution in volume caused by the passage of the gas through palladium chloride is considerable, the presence of hydrogen or carbon monoxide would be indicated, in which case their determination is advisable. For this purpose, the apparatus for supplying hydrogen is disconnected, and a palladium tube is connected to the end of the gas apparatus—the other end of the palladium tube is connected to an absorption pipette containing water. The palladium tube is immersed in a beaker of water at 90-100 degrees C., and oxygen is passed through the tube to oxidize any hydrogen present. The water is drawn to a specified point in the stem of the absorption pipette, and the capillary tube of the apparatus is filled with water from the explosion pipette. Fifty cc. of natural gas are then introduced into the burette and measured, the carbon dioxide is removed, and the gas is passed through fuming sulphuric acid. About 10 cc. of oxygen are added, and a reading is taken. The gases are then passed back and forth through the palladium tube, which is immersed in hot water at first and then in cold water to cool the gas. The gas is finally brought back into the burette, the water in the pipett ebeing at the previous level, and a reading is taken. The decrease in volume is noted as Contraction "a." The gases are then passed into potassium hydroxide, drawn back and measured; the diminution in volume is Contraction "b." From a study of the contractions formed in the combustion of carbon monoxide and hydrogen, it is seen that

$$CO = b;\ H_2 = (2a - b)\ 3.$$

ERROR IN ASSUMING THE GAS TO BE METHANE AND ETHANE

The basis of the determination is in reality the volume of combustible gas (equal to A—Oxygen consumed) and the oxygen necessary for combustion (Oxygen consumed = Oxygen added — C.). Both are accurately determined, consequently the combustibles present and the amount of air necessary for their combustion as calculated from the analysis is correct. The carbon dioxide formed on combustion has not been determined but can be calculated for any and all paraffines which have the general formula C_nH_{2n+2}. If n represents the number of carbon atoms in the molecule, and p the total volume of paraffines, then, by reasoning analogous to that given when the formula were derived, np equals (Oxygen consumed — ½ A). But np equals the carbon dioxide and is independent of any particular paraffines that may be assumed to be present, therefore, the carbon dioxide formed on the combustion of the gas, as calculated from the analysis, is correct. As regards the heat value calculated from the analysis, Thomson has shown that the heat value of a paraffine is equal to K + nD, where K and D are constant factors. The heating value of the combined portions of natural gas then is (K + nD) p or Kp + Dnp. It has been shown that p and np are correct, depending upon the factors A, C and Oc. Therefore, the heating value of natural gas as calculated from the analysis is correct.

Charcoal Precipitation of Aurocyanide

A Description of the New Moore-Edmands Process With Discussion of the Underlying Theories

By A. W. Allen

THE use of charcoal as a precipitant of gold from aurocyanide solution has never reached the point of importance where it might be considered as a serious rival to zinc. Lump charcoal was used in the early stages of the cyanide process on a commercial scale in Victoria, Australia; and has been adopted to a small extent elsewhere but without success. The only exception to this statement may be found in the case where gold from waste solution discharged from a cyanide plant to reduce fouling, or to prevent undue accumulation of liquor, is recovered by this method. Appreciable quantities of gold may also be saved, by the use of charcoal, from decanted solution from slime tailing dams, or where the seepage from tailing-filled stopes carries small amounts of dissolved metal. In such instances the results may be termed satisfactory only insomuch as an amount of gold is recovered that would otherwise be lost. Effort is seldom made to effect a complete saving, the equipment is usually neglected during the month and attention only paid to it when the urgent need of an addition to the gold yield is in evidence.

On a commercial scale the substitution of lump charcoal for zinc could not be considered satisfactory from any standpoint. A large amount of charcoal is needed to recover a small amount of gold. The product, even after burning, is bulky; and the gold content of the ash to be smelted is exceedingly low. The efficiency of the process, unless an enormous amount of charcoal is used, is unsatisfactory. No progress in the adaptation of charcoal as a means of recovering gold from cyanide solution has been made for many years; and its use in this connection has been considered as unfeasible as the cyanide process itself was viewed before MacArthur and Forrest invented a method of procedure capable of practical application.

The Work of Moore and Edmands

A noteworthy advance is now due to the efforts and ingenuity of K. Byron Moore and H. R. Edmands who have resurrected the question and, after exhaustive laboratory experiments, have perfected a system of precipitation with charcoal slime which apparently leaves little to be desired. The method has been finally adopted at the Yuanmi mine, Western Australia, and is also being practised in South Africa. In the former case a foul and complicated cyanide solution containing antimony and arsenic is successfully freed of its gold. With zinc precipitation there was trouble and loss from high tail solution, the cost of zinc was considerable, and, even after extensive refining, the bullion was comparatively low grade. By the adoption of the new charcoal method the effluent from the extractors may now be reduced to contain but a trace of gold. The bullion, after simple smelting, is valued at about $20 per oz., as compared with about $17 per oz. for a similar product after zinc precipitation. The saving in the cost of recovery of the gold is about 25 cents per ton of ore treated.

After a year of operation a statement of result was published by H. G. Walton.[1] No fouling agent similar to the double zinc cyanide appears in the solution; and such a result would automatically effect a saving in cyanide consequent on a permissible reduction of cyanide strength in the solution. No figures are available in this connection, but in a later publication by H. R. Edmands[2] it is to be noted from comparative results of the use of zinc dust and charcoal that the necessary cyanide strength in the case of zinc was five times as much as when charcoal was used.

MOORE-EDMANDS EXTRACTOR

[1] Report of the Department of Mines of West Australia, 1916.
[2] Bull. Inst. Min. & Met., London, March, 1918.

The principal features of the new Moore-Edmands process are as follows:

Preparation of Charcoal

The charcoal used is water-quenched when red-hot, washed, and wet ground in a small ball-mill to as fine a product as possible.

Moore-Edmands Extractor

A special form of extractor is used consisting of a miniature vacuum-filter of (what is known outside Australia as) the Butters type. The suspended frames are 2 ft. 3 in. x 2 ft. 9 in., and there are 21 to each extractor. The filter media are, respectively, coconut matting as a support, filter canvas, and an outer protective layer of calico. The extractor is shown in Figs. 1 and 2 and contains four agitators in the bottom of the hopper, attached to a horizontal shaft.

Method of Operation

Solution and charcoal pulp are pumped to an extractor and the vacuum started as soon as the leaves are properly submerged. Fresh solution is added concurrently with the formation and maintenance of cake, and the supply of liquor is such that a continuous stream passes through the charcoal. The propellers are kept in operation and percolation continued for 24 hours, or some other pre-determined time. The vacuum is then released, the charcoal cakes dropped to the hopper bottom of the extractor, emulsified, and re-formed on the filter leaves by the application of vacuum. This cycle of operations is continued at intervals as long as the charcoal possesses sufficient activity to precipitate the gold. The extractors are worked in series, the one whose cakes are approaching gold saturation receiving the richest solution, the tailing from this going to the second extractor, and being finally impoverished by contact with fresh charcoal.

Washing of Charcoal-Gold Precipitate

The final emulsified charcoal pulp, loaded with gold, is delivered to a clean-up press, washed, and dried with compressed air.

Calcining

Burning of the charcoal is carried out in braziers, 18 in. x 18 in. x 18 in., and made of ½-in. aperture stout wire screening. The operation is carried out in a locked steel chamber and takes about 48 hours.

Smelting

The flux adopted is as follows:

Precipitate	100 parts
Borax	40 to 50 "
Sand	50 "
Salt	10 "

Plain graphite crucibles are used and have a long life.

Fineness of Bullion

A comparison of results with charcoal and zinc precipitation is as follows:

	Charcoal	Zinc
Gold	954.4 fine	825.2 fine
Silver	7.0	21.9
Base	38.6	152.9

Weight of Charcoal Required

Walton states that 1 ton of charcoal will precipitate 770 oz. of gold by this method, and that the weight of calcined ash is about one-third of the original weight of the charcoal. Edmands' gives the percentage of gold in the calcined ash as from 10 to 14 per cent. The enormous increase in the precipitating power of charcoal by fine grinding is indicated by the fact that, by the old method of percolation through extractor boxes, 5 tons of charcoal was needed to precipitate about 700 oz. of gold.

The charcoal used at the Yuanmi mine is an otherwise waste product from producer-gas manufacture. The wood used is locally known as mulga scrub and is a variety of the acacia family which includes several wattles indigenous to Australia. It is possible that the character of the wood, which in some species contains a considerable amount of tannin, has a favorable effect on the final result. Different woods have widely different precipitating values when made into charcoal and used for the recovery of gold from cyanide solutions.

The sole drawback to the method appears to be the amount of material to be smelted. The actual smelting entails no difficulties and there is little corrosion of crucible. The latter might even be reduced by an alternative flux. In medium- or large-sized plants such low-grade precipitate is best smelted in large tilting furnaces—an arrangement permitting the periodic pouring of slag only, the gold being allowed to accumulate in the bottom of the crucible, where it refines. This method minimizes the temporary loss by shotting met with when small charges of gold are poured through a large bulk of cooling slag. The furnace also acts as a safe during night operations, when there is less available supervision, and when minimum handling of bullion is advisable.

Theory of Charcoal Precipitation

The various theories propounded to account for the action are as follows:

Occluded Oxygen Theory.—It has been suggested that an insoluble gold cyanide and sodium cyanate is formed.

Electro-Deposition Theory.—This theory assumes that gold is deposited as metal as the result of electrical action. It is disproved by the fact that there is no corresponding liberation of cyanide during precipitation.

Carbon Monoxide Theory.—The assumption that a chemical action takes place between the occluded carbon monoxide gas and the aurocyanide whereby a carbonyl aurocyanide, or other analagous compound, is formed has been widely accepted. Criticism of this theory must be mainly constructive and in opposition. All the asumptions are hypothetical and no parallel action is known with charcoal.

Adsorption.—The theory that the precipitation is due to a simple adsorption of aurocyanide—$KAu(CN)_2$—is supported by the following facts:

1. The loss of cyanide, by titration, agrees with theoretical considerations.
2. Precipitation efficiency varies inversely with the concentration of the solution, and a true absorption curve may be plotted from actual results.
3. Precipitation is proportionate to surface exposed, finer grinding giving better results.

4. Methods of preparation of the charcoal which drive off occluded gas (quenching when red-hot and wet grinding), and so increase surface energy of the charcoal, result in a more favorable action.
5. The addition of acid accelerates precipitation whereas alkali retards it. This is a parallel instance of the obstructive effects of hydroxyl as compared with hydrogen ions as demonstrated by Lachs and Michaelis[5] in connection with the adsorption of an aqueous solution of potassium chloride by charcoal.
6. The adsorbed gold compound is insoluble in ordinary solvents although released by the addition of a solution of different surface tension, such as a soluble sulphide—a parallel to the case where picric acid adsorbed on platinum may be released by alcohol, although unaffected by water, its natural solvent.

New York, N. Y.

Tariff Commission Conference on Antimony, Quicksilver and Tungsten

The United States Tariff Commission is now engaged in the systematic assembly of information on the various industries of the country, with a view to presenting it in well-digested form for the guidance of Congress. The Commission is receiving valuable assistance from manufacturers, merchants, consumers, and the public, and this co-operation is being continually extended and strengthened. Engineering societies and Government bureaus are consulted as the work progresses. Attention will be given to labor conditions.

A conference will be held at San Francisco in the Assembly Room of the Chamber of Commerce during the week of June 24th on antimony, quicksilver and tungsten ores and products, to which the producers, importers and consumers interested in these metals from all parts of the country will be invited. The conference is for the purpose of securing information in regard to disturbances and changes in these American industries. The topics to be discussed fall under three heads:

(1) The condition of the American industry before the war, in relation to foreign competition;
(2) The effect of the war on the industry;
(3) Competition with foreign producers after the war.

The conference will take the form of an inquiry into the effect of the war upon production, markets, plant expansion, increase in cost of materials and wages since 1914, and post-war competition—all of which will be considered in their bearing upon the tariff. Imports and exports, relative foreign and domestic costs of production of metals and products, and the adequacy of American ore deposits for domestic needs will be among the subjects discussed.

A separate hearing on tungsten will be held in Denver, Colorado, on Monday, June 17. This meeting will be opened at 10 a.m. in the United States District Court Room at the new Post-Office Building, and the proceedings will be of the same general nature as at the California conference. At San Francisco, the hearing on antimony is to be called at 10 a.m., Monday, June 24; quicksilver Wednesday, June 26; tungsten Friday, June 28.

The Commission hopes that the meeting may fairly represent the various interests involved. General notice and invitation is being sent to those concerned.

Determining Copper Minerals in Partly Oxidized Ores

By Felix Cremer

THE article of Charles E. Van Barneveld and Edmund S. Leaver[1] on the determination of so-called oxides in mixed ores, gives me an opportunity to state my own ideas on the subject and review a few facts connected with my work in that direction. In January, 1917, I took charge of the first experimental work to be conducted by the Andes Copper Mining Company at Potrerillos, Chile, for the study of the best method of treating the ore from their large copper deposit. This consists of a great mass of eruptive rock, variously called, syenite, rhyolite and porphyry, ejected through a limerock formation and greatly altered in texture and composition in most places, thus giving the whole a very complex and heterogeneous structure. One of the features of the decomposition of these rocks has been the percolation of copper-carrying solutions, originating with some of the rocks of a primary character, and resulting in the deposition of new copper minerals in local deposits of irregular shape, size, structure, composition and richness. While in some places the processes of repeated solution and precipitation resulted in deposits of very high-grade ore, of more or less limited extent, in other places the elementary rocks do not seem to carry more than traces of copper.

Some of the richest ore, near the surface, has been extracted in the past by the natives, but this ceased to be profitable where it became necessary to do much dead work to find the rich ore in so much low-grade material. Therefore, nothing remained but to mine the ore by a more or less selective process on a large scale, the problem being to conduct the operations in such a way that a sufficiently low cost would allow portions of the deposit to be handled in bulk, i.e., without any attempt at descriminating, locally, between rich and poor ore, and then to find these portions and outline their boundaries.

Copper Minerals in Potrerillos Deposit

The principal copper minerals identified in this deposit are chalcorite, chalcopyrite, some bornite and covellite, chrysocolla, some malachite, atacamite, brochantite, cuprite and native copper; but it is important to observe, for the possible treatment of the oxidized ore by film-sulphidizing and flotation, that little of the silicates of copper, constituting the main portion of the oxidized minerals, appear strictly as chrysocolla, but simply as copper-impregnated quartz, the copper being preserved in all proportions, from a slight greenish stain to the correct percentage corresponding to the mineral chrysocolla.

The relative amounts of sulphide and oxides in the deposit, estimated from the reports of the drill men—these again basing their opinion on the evidence from panned drill-hole samples—is about half and half; but, as this process of arriving at the facts is not as precise as might be desired, the figure is subject to more or less correction. This, however, is not as simple a matter as it would seem at first glance, for reasons which will become apparent from what follows:

[1]This journal, Feb. 18, 1918, p. 203.

At the time I commenced to work on this matter, two methods of determining the so-called oxide copper, namely, were known to be in use, heating the sample with a 5 per cent solution of sulphuric acid, the one method calling for a 24-hour treatment at room temperature and the other for one-hour treatment near the boiling point. The ammonia method, mentioned by Van Barneveld and Leaver, had not come to our knowledge, nor would have inspired much faith in its utility on chemical considerations, and does not seem to be much in use. The other two had been the classical methods for a number of years in all the leading American copper mines, at home and abroad, where the grave objections to them did not seem to have been fully realized, as no serious attempt was made to devise a better method.

Test of Sulphuric Acid Method

My first step, in putting the H_2SO_4 method to a test, was to try it on a high-grade oxidized ore, carrying about 20 per cent cuprite and 10 per cent chrysocolla, which showed at a glance that the copper from the cuprite was not all dissolved, but that part of it remained insoluble as metallic copper. This would naturally appear in the assay returns as sulphide copper, in the same manner as all native copper would appear in the same column.

When this weakness of the method was discovered, an attempt was made to find a solvent for this metallic copper. While experimenting along that line it was noticed, under the microscope, that few if any samples delivered to the laboratory were free of metallic iron, which was then identified also by ocular inspection of the pannings from the samples. In some instances these carried practically nothing but iron, when the drillers had attempted to straighten out a crooked hole by filling the bottom up with tin-cans and similar material. Of course this added another error to the determination, operating in the same sense as the two first mentioned, by precipitating a certain amount of copper from that taken into solution by the acid.

Against these three sources of error, all tending to show higher sulphides at the expense of the oxides, there is the solubility of the sulphides by sulphuric acid mentioned in the article referred to, which escaped our notice as the method was soon discarded after its defects had become known. This probably explains some of the erratic returns obtained previously which could not be accounted for by the then known facts. In regard to this solubility of the sulphides in dilute H_2SO_4, I am not quite convinced that this is due to the direct action of the reagent. In some cases of a similar nature we have traced the apparent attack of sulphuric acid on sulphides to the presence of chlorides and nitrates in the ore, and it might not be amiss to test this point by repeating Messrs. Van Barneveld and Leaver's experiments on an ore thoroughly leached with water previous to the addition of the acid, which, of course, must also be free of chlorine and nitric acid.

Unreliability of Sulphuric Acid Method

When it began to be realized how utterly unreliable the H_2SO_4 method was for the determination of oxide copper, steps were taken to find a better method. For a while our hopes were placed on hydrogen peroxide, which, under the microscope had been found to dissolve the metallic copper in dilute H_2SO_4, and proved afterwards to attack natural sulphides only slightly. Artificial sulphides, however, i.e., those precipitated from copper solutions by H_2S, were freely attacked, and since this method would not have solved the metallic-iron difficulty anyhow, it was soon abandoned.

On the other hand, phosphoric acid, which also proved a good solvent for all carbonates and silicates, did not attack the sulphides (natural or artificial), nor were its copper salts affected by metallic iron, but neither it did not dissolve metallic copper. In searching, therefore, for a solvent for this, it was found in ammonium chloride which dissolves metallic copper more readily than any other reagent known to us. Thus a combination of phosphoric acid and ammonium chloride suggested itself and was tried on a variety of our ores, with results that seem to place the method on a par, at least, with the sodium tartrate method of Hunt & Thurston and the sulphur dioxide method of Van Barneveld and Leaver. The latter method was not known to us before my recent separation from the Andes Copper Mining Co., and therefore could not be tested, but with the tartrate and phosphoric acid methods a number of parallel determinations were made which seem to indicate that there is no difference between the two for low-grade ores as far as results are concerned, and that, therefore, the question of preference between the two methods would have to be settled on points of manipulation.

Insufficient Grinding Caused Discrepancies

For some time unaccountable discrepancies in the results from the same sample with the phosphoric acid method, especially with high-grade ores, seemed to throw a doubt on the value of the same, but it appears that all can be traced to an insufficient comminution of the sample. The standard practice in our laboratory had been to crush to 80-mesh, and I believe with Messrs. Van Barneveld and Leaver that too much attention to this point cannot be given, the safest course being to grind all samples for these determinations to 150-mesh.

Unfortunately time did not permit these tests to be carried to a definite conclusion in regard to this and other points, and the writer would be glad to see the method subjected to a searching scrutiny so as to determine positively which of the three proposed will be the most useful for the chemist.

Among the difficulties that presented themselves in the operation of the method early in its history one was due to the peculiar conditions prevailing at the Potrerillos laboratory. This was not equipped with an electrolytic precipitation system for lack of current, and all copper determinations had to be made by volumetric methods, the cyanide for ordinary purposes and the iodide for more accurate work, the latter being too tedious for application to a large number of assays. After titration with the cyanide, however, the phosphate solution showed a decidedly yellowish tint, which greatly interfered with a sharp endpoint. After some trials with various materials Mr. L. F. Clark, our chief chemist, who [illegible] all our experimental work has been of the greatest assistance owing to his resourcefulness

and originality in solving chemical problems, found that the addition of some burnt lime (from our lime kiln), after solution of the copper had been effected and before the contents of the flask had been made ammoniacal completely removed the objectionable yellow color and left a crystal-clear liquid with which to finish the titration.

Improved Laboratory Method of Determining Copper

The operation of this method is exceedingly simple. One gram of the sample is weighed and introduced into an ordinary 500-c.c. flask with flat bottom, covered with 20 c.c. of a 15 per cent H_3PO_4 solution and an equal amount of a 20 per cent NH_4Cl solution, and boiled gently for some ten minutes. After cooling somewhat, a pinch (mustardspoonful) of burnt lime was given, the flask thoroughly shaken, and 25 c.c. strong ammonia water added. This was given another short boil, the ammoniacal copper solution filtered off from the residue, allowed to cool and titrated in the ordinary way with cyanide solution. Occasional check determinations with the iodide method gave concordant results.

The exact amounts of H_3PO_4, NH_4Cl and NH_3, as also the proper strength of the solutions could not be worked out in the allotted time, but the proportions given above answered well for all ordinary samples, up to 2 per cent and 3 per cent oxide copper. Possibly they might be reduced to advantage. On very high-grade oxide ore, say 30 per cent, to the best of my recollection a second treatment, after filtering off the dissolved copper, still yielded appreciable amounts, though I am inclined to believe that with sufficiently fine grinding this may not be the case.

Several trials with this mixture on various sulphides, both natural and artificial, to test their solubility, yielded negative results.

What Is "Oxide" Copper?

We now come to the question of what we are trying to accomplish by devising a method for the determination of oxide copper. What is oxide copper? And, is it really the oxide copper that we are endeavoring to determine? Evidently, native copper is not oxide copper, though we purposely are trying to find a way that will include it in the results, and are disappointed that the H_2SO_4 method does not do so. It is, then, to say the least, misleading to call these oxide copper determinations.

Similarly, only by some stretch of the imagination can we call the carbonates, silicates, basic sulphates and oxychlorides, "oxides." It would be better to include all of these, together with the real oxides (cuprite and melaconite) and native copper under the term of "oxidized copper." But, do we really want to know the amount of all this "oxidized copper" in technical determinations? It may be useful, occasionally, for geological or similar objects, but I know of no metallurgical process where such a knowledge could be of any utility and that, after all, should be the criterion by which to judge the value of a method. And so we come to the conclusion that each metallurgical process should have its own laboratory method, and give it its distinctive name to avoid confusion.

Effect of Iron on Drill-Samples

For instance, in the simple leaching of ores with sulphuric acid: If it were not for the presence of metallic iron in the samples from the drill-holes and bucking board, there could be no better method for the laboratory than treatment with dilute H_2SO_4, as it only represents the large scale operations *en miniature*. Unless, therefore, the samples come from other places than drill-holes and are not reduced to powder in contact with iron, a method must be found that will eliminate this iron, either by dissolving it in something that will not attack the copper oxides or some other indirect way. Removal of the iron with a magnet does not seem feasible without losing at the same time much of the sample, even if one had the assurance that all iron could thus be extracted. But, it should be possible to replace the iron completely by copper with $CuSO_4$ and then apply the dilute H_2SO_4 which will, of course, leave untouched this new copper as well as that from cuprite and the native copper, thus furnishing an accurate measure of what the leaching operations should yield. Copper-ammonium chloride might possibly be used to advantage in place of copper sulphate, provided it could be determined positively that it had no effect on the copper oxides.

Each Process Requires Special Method of Determining Copper

But, simple leaching is not the only process copper mines have to deal with. There is flotation, in acid, neutral and alkaline pulp, in sweet water and in seawater, and with all kinds of chemical agents or "drops." None of the methods touched upon in this review will help us here; each combination of processes will require one of its own, and some will prove eventually none too simple.

Take, for instance, oil flotation in acid pulp. What we need to know in this case is how much of the copper in the form of floatable sulphides is in the ore, how much in the concentrate, and how much in the tailing. In order to do this we have first to determine the total copper. Then we have to find out by some such method as described above how much of it goes into solution in the acid, leaving us, by subtraction, the amount that should be in the form of sulphide and therefore appear in the froth—provided the metallic copper acts as sulphide in that respect as some people assert and I believe to be the case, but which many people deny. If it does not, then we have to try to determine this amount of metallic copper, perhaps by amalgamation, and make allowance for it, not forgetting, in making our metallurgical balance sheet that some portion of the oxidized copper minerals must necessarily be tangled up in the gangue floated with the sulphides.

And so it will be with floating in an alkaline pulp, where the situation may, or may not be still more complicated, according to circumstances. And so it will be also with all other processes, already in use, like the combined leaching and flotation, ammonia process, etc., or those still to come, each one requiring its own laboratory methods.

Santiago de Chile

Chemistry in the Petroleum Industry*

Commercial Development—Gasoline by the Burton Process and Scientific Aspects

By William H. Burton, Ph.D.

FOUR years ago we assembled to witness the awarding of the Willard Gibbs Medal to Dr. Ira Remsen, of Johns Hopkins University, and one year ago we met for the same purpose in the case of Prof. Edward W. Morley, of Western Reserve University. Both of these gentlemen were honored preceptors of mine, and it was indeed a great pleasure to me to be present on those occasions. I never thought, however, that I would ever be the fortunate recipient of the Willard Gibbs Medal, but the unexpected and improbable very often occurs, and it is so in my case. I therefore hasten to extend to the Chicago Section of the American Chemical Society my deepest appreciation of the honor it has conferred upon me. This event reminds me of a most prominent feature in Dr. Remsen's course of instruction, namely, that the best preparation for a career in technical chemistry is thorough training in the pure science, and I was equally impressed with the introductory sentence of Dr. Morley's address last year, when he said "The best incentive for research work is the work itself." Both of these great teachers have exemplified these principles most happily in their professional careers, and I trust you will find my remarks thoroughly imbued with the influence of their invaluable instruction.

Early History of Petroleum

In considering the part that chemistry has played in the petroleum industry, it might not be unwise to review, briefly, the early history of the industry in this country. You have all heard of the first oil well, drilled by Col. E. L. Drake, near Titusville, Pa., in 1859. Prior to that time petroleum was found in small quantities floating on the surface of springs or small streams of water in western Pennsylvania, and this oil was claimed by the Indians to have marvelous curative properties in the treatment of every manner of disease. The white man, with true commercial instinct, sold the oil in bottles as a general cure-all. The demand for the oil exceeded the supply, and Colonel Drake conceived the idea that if the oil came to the surface of the springs and rivers, there must be large quantities of it in the underlying strata of the earth. He, therefore, with the most primitive machinery, drilled a well near Oil Creek, in western Pennsylvania, and before he had proceeded 100 feet into the ground the oil appeared in such large volume that it was difficult to take care of it.

At that time there was a great need for a cheap and convenient illuminating material to supplant the expensive animal and vegetable oils which were used for that purpose. Samples of petroleum (prior to Drake's work) had been sent to Professor Silliman, of Yale College, who distilled the oil and made separations according to the boiling points of the various fractions. In his report he stated that portions of these distillates might well be utilized for illuminating purposes. The promoters of the oil business acted upon Professor Silliman's suggestions, and this was the inception of the petroleum refining industry in this country.

Chemical Problems Arise

For a great many years after Professor Silliman's investigation chemistry played a very small part in the practical workings of the refining of petroleum. The refiner learned to treat the illuminating oil distillate with strong sulphuric acid and alkalis, which improved the character of it somewhat, but the methods of refining were crude and wasteful. The only portions of the petroleum which were used at first comprised the fractions boiling between 100 and 300° C., which constituted somewhat over 50 per cent. of the total mass of the crude oil. The low boiling fractions which we now comprise in the generic term of "naphthas" were thrown away, as were also the high boiling residues, called "tar." The tar, however, was soon utilized for preparing lubricating oils of very indifferent quality. It was not until about 1870, when M. L. Hull, of Cleveland, Ohio, first devised the so-called "vapor stove," that the naphtha fractions of the oil were utilized. But even then the uses for the naphtha fractions did not cause a demand equal to the supply, and much of the naphtha was wasted, a common practice being to throw it into the creeks and rivers, where it evaporated. Millions of gallons of this material, now indispensable for automobiles, were thus lost.

These conditions continued until 1885. Up to this time practically the sole source of petroleum in America was western Pennsylvania. But in 1885, or '86, petroleum was found in western and northwestern Ohio, near the town of Lima, and the fact that this oil contained from one-half of one per cent. to one per cent. of sulphur attracted immediate attention. The ordinary refining methods of distillation and treatment with sulphuric acid and alkali were found to be totally inadequate to secure refined illuminating oils of suitable quality. Therefore, the industry turned to the chemist to solve the problem of extracting the sulphur, and producing satisfactory products.

No Petroleum Chemists

It is very curious that from the early days of the industry until the discovery of Lima oil, there seemed to have been prejudice on the part of practical oil men against the chemical fraternity. Why this should have been so is not entirely clear, but I think that one reason might be the fact that manufacturers frequently called upon chemists of general training to solve some particular problem connected with their business, ignoring the fact that the chemist probably had had no practical refining experience. The chemist therefore probably offered suggestions which were totally impracticable and the manufacturer, seeing this fact, was not particularly impressed with the chemical profession as a possible aid to his business. Whatever the reasons may have been, it was a fact that in 1885, with the discovery of Lima oil, there was scarcely one trained petroleum chemist in the United States. The oil refiners, however, were forced to turn to the chemical profession for the solution of their problems, and the chemists had to become somewhat trained in the refining business before they could offer a practical solution for the elimination of sulphur from the oil. This was the starting point for a better feeling between the chemical profession and the petroleum in-

*Address by William H. Burton, Ph.D., before the Chicago Section of the American Chemical Society upon being awarded the Willard Gibbs medal.

dustry, and from that time, more and more chemists have been employed in the refining industry, until today the larger refineries depend almost entirely upon chemists to manage, not only the refinery as a whole, but the various departments of the same.

Training Chemists

In selecting a subject for an address on an occasion like this, it is customary for the candidate to choose as his subject the line of work the results of which have presumably been the reason for his being selected, and I have followed the usual procedure. It is perhaps difficult to describe the work that has been done without appearing to be somewhat boastful. However, the remainder of my remarks will be devoted largely to the results secured by the Chemical Department of the Standard Oil Company of Indiana, and I shall try to recount, briefly, the facts concerning those things which have been accomplished, and eliminate, so far as possible, the personal equation. I entered the employ of the Standard Oil Company nearly thirty years ago, at the time that the Lima oil problem was very much in evidence, and it was perfectly clear that there was a great field for chemical activity in the petroleum industry, provided the refining companies were willing to educate the chemist in the business, before expecting that the chemist would be of much value to them. The Standard Oil Company signified this willingness, and from 1890 until the present time there have been a great many chemists employed by that company, most of them being in its employ today, some as active chemists, some as general managers, and some as managers of various departments. The result has been that the refining of petroleum, instead of being a haphazard process, has been largely systematized and improved, so that when we do certain things we feel confident we will secure certain results, and the great variety of useful products made from Mid-Continent petroleum today indicate the part that chemistry has played in the petroleum industry.

The Gasoline Problem

As I indicated a few minutes ago, in the early days the supply of low boiling fractions of petroleum were largely in excess of the demand. This condition of things existed from the inception of the business until the invention of the internal combustion engine. With the advent of this machine, the demand for low boiling products, included in the commonly used name of "gasoline," became tremendous. To illustrate: In 1900 our Company was able to sell only one million barrels of naphtha products. It could have made much more, but there was no demand for it. You will recall that the automobile was devised about that time, and although the use of it grew slowly, we could see a constantly increasing demand for naphtha products to run these machines, until by the year 1910 the demand had more than trebled, and it was perfectly obvious that something would have to be done to increase the supply of these products.

In those days, the average yields of various products of petroleum were about as follows:

	Per Cent.
Naphtha products	18
Kerosene or illuminating products	30
Lubricating products	10
Loss	3

leaving about 40 per cent., which was sold for gas making or fuel purposes in lieu of coal. It was clear that the problem was to convert the high boiling fractions existing in the fuel and gas oil into low boiling fractions needed by the internal combustion engine. It has long been known that superheating the vapors of petroleum at atmospheric pressure caused dissociation of the molecules, producing very low boiling fractions and very high boiling fractions, as is evidenced by the ordinary Pintsch gas, with which you are all familiar, but the low boiling fractions produced by these superheating methods are not suitable for internal combustion engines, and the losses due to fixed gases are very great. It was found that anhydrous aluminum chloride exerted a very marked effect upon the high boiling fractions, converting some of them into low boiling fractions entirely suitable for automobile purposes, but the very high first cost of the aluminum chloride, together with the fact that to make the process successful an inexpensive method must be devised for restoring the aluminum chloride, rendered this process out of the question. We worked for almost two years trying to devise a practicable method for securing this most desirable result, first by superheating and dissociation at high temperatures, but at atmospheric pressure, and secondly, by the employment of various reagents; but our efforts were not successful; on the other hand, we met failure in every direction.

The Burton Process

It had been known for a long time that distillation of petroleum products under pressure resulted in their dissociation and production of some low boiling fractions and some high boiling fractions, but this process never had been applied in a practical way because to a practical refiner the distillation of oils under high pressures did not appeal, owing to the extreme hazard due to explosions and fires; but having tried everything else that suggested itself, we decided to attack the problem from the pressure distillation standpoint.

To the layman, distilling oils under pressure would present no particular difficulty. The distillation of water is done every day in our steam boilers, and why should one fear to do it in the case of oil? But when you consider that the distillation must take place at temperatures ranging from 350 to 450° C., where the tensile strength of steel begins to diminish very rapidly, and when you consider that steel, at such temperatures, in the presence of carbonaceous matter (and even free carbon, which often comes as the result of pressure distillation), is very likely to absorb such carbon, become crystalline and lose its tensile strength, you can readily see why the practical refiner shivered at the prospect of doing work in this way. We consulted refiners who had been in the business a great many years. We advised with mechanical engineers for whatever suggestions they might offer, and it must be confessed we did not receive very much encouragement. Since we found, early in our work, that we would require a pressure of over five atmospheres, you can easily see that we approached with considerable respect the problem of building practical apparatus that would stand this pressure in actual daily service. One refiner doubted the practicability of carrying over one pound pressure, another refiner suggested the probability of

explosions, due to polymerization of the vapors under heat and pressure, such as occur when acetylene is compressed. However, we were able to secure a very liberal sum of money to try the scheme on a large scale, and the worst that could happen would be to burn up our plant and fail in our efforts. So we went ahead.

The first large still we built had a charging capacity of 6,000 gallons of heavy oil, and about the first difficulty we encountered was serious leaks around the rivet heads and along the seams. The workmanship in building the still was good and it would have been satisfactory as a steam boiler. We found that oil, at high temperatures and pressures, leaks worse than water, and a leak always causes a fire of an intensity directly proportional to the amount of the leak. It was difficult at first to secure boilermakers who would calk these leaks while the still was under pressure. In many cases when we calked one leak another would form. Finally nature came to our aid and we were gratified to observe that as the still continued in service the leaks became less serious. The oil carbonized under the influence of the high temperature and the carbon deposits stopped the leaks.

There were many puzzling problems to be solved. We had to devise a safety valve that would operate freely in spite of the intense heat and presence of carbonaceous matter. The entire apparatus had to be constructed in such a way as to insure ease of operation and freedom from excessive repairs. Distilling oils under pressure always results in the production of so-called "fixed gases." The disposition of these gases, at first, was troublesome. We found that in some cases the heavy oil with which we started evolved more gas than was needed to maintain the desired pressure in the apparatus, whereas other oils evolved an insufficient amount of gas for this purpose. This was an embarrassing situation, but we converted an obstacle into an aid by arranging a large number of stills in parallel so that the superfluous gases from some stills were conducted to others that needed them and this plan gave us a perfect method for securing uniform pressure and control—a most essential feature in the work.

The first large still we built, as I have mentioned, had a capacity of 6,000 gallons, and by starting with fuel oil products having boiling points ranging from 200 to 350° C., we were able to secure a very substantial yield of a product having boiling points ranging from 50° C. up to 200° C., and to our great gratification the losses incurred thereby were trifling, averaging less than three per cent. We were astonished, also, to find that the high boiling residues thus produced yielded a product almost identical with the natural asphalt which is mined in large quantities in the island of Trinidad. Evidently we are doing artificially what Nature has done in ages gone by, viz.: distilling petroleum under pressure.

It would require a long time to describe how we solved some of the various problems that arose in connection with this process. From the single 6,000-gallon still we first built, we now have over five hundred stills of a larger capacity. At first our practical men were very loath to accept these pressure stills as a going proposition. They were afraid of them. The minute the slightest thing happened they would be likely to run. But, fortunately, we had no fires or serious accidents for the first two or three years, and when we finally did have a rather bad fire, the men had secured enough self-confidence to stand by their guns, and the damages were repaired quickly and the work went on, so that today the work pressure distillation is carried on in our refineries in connection with the regular routine work, and most of us have forgotten that a few years ago we were met with discouraging protests when we proposed making naphtha products in this manner. During the last five years there have been made in this country over 20,000,000 barrels of gasoline or naphtha products by the use of these stills, and we trust that the future will show a largely increased production (by this process) of this indispensable material.

Future Work for Chemists

Although we know very little about the reactions that occur when petroleum is distilled under pressure, it may be interesting to speculate a little on this subject. Let us start with the paraffin $C_{14}H_{30}$ and see what might happen.

$$C_{14}H_{30} = C_{13}H_{28} + CH_4$$
$$C_{14}H_{30} = C_{12}H_{26} + C_2H_4$$
$$C_{14}H_{30} = C_{14}H_{28} + H_2$$
$$C_{14}H_{28} = C_{12}H_{26} + C_2H_2$$

$$C_{14}H_{30} = 4C_2H_2 + 4CH_4 + C_2H_2 \text{ (All gas)}$$

$$2C_{14}H_{30} = C_8H_{18} + C_{20}H_{42}$$
$$C_{20}H_{42} = C_4H_{10} + C_{16}H_{32}$$
$$C_{12}H_{24} = C_{10}H_{22} + C_2H_2$$

$$2CH_4 + C_2H_2 = C_3H_{10}$$
$$3CH_4 + 2C_2H_2 = C_7H_{16}$$
$$C_2H_2 + 2H_2 = C_2H_6$$

We feel confident that the finished gasoline contains such paraffins as C_8H_{18}, $C_{10}H_{22}$ and $C_{12}H_{26}$, but one of the most interesting results is the formation of free hydrogen as shown in one of the above equations.

The fixed gas formed in pressure still work gives the following analysis:

	Per Cent.
CH_4	56.3
C_2H_6	25.8
Unsaturated hydrocarbons	8.5
CO	.8
H	7.4
Condensible vapor	.6
Undetermined	.6
	100.00

It would seem almost impossible for hydrogen to be set free under the conditions mentioned above, but the analysis of the gas proves this to be a fact. It also seems probable that, under the influence of heat and pressure, the gases of the different series polymerize to form saturated products that are useful.

It is perhaps to be regretted that the chemists engaged in the petroleum industry have contributed so little to the purely scientific side of the subject. Others have done considerable work along this line, but for various reasons, the petroleum chemists have not. The chemistry of petroleum offers a most inviting field for

scientific research, and I trust the time will come when this subject will receive the attention it deserves, and when that time does come, I sincerely hope the chemists who have been trained in the practical work will be in a position to do their bit for the advancement of our knowledge of the chemistry of petroleum.

Shares Tribute with Associates

It would be most unjust and unfair for me to accept at your hands the award of the Willard Gibbs Medal without acknowledging to you the invaluable assistance that I have received from my associates, several of whom I see before me in this room. They are fully entitled to their share in the honor that goes with this medal. Some of these gentlemen are chemists and some, although not having a thorough chemical training, are worthy to be called chemists.

It has fallen to my lot to be the director of the work I have just outlined, but it never could have been brought to a successful termination without the valuable suggestions, indefatigable labor and loyal support of my associates.

The Effect of Boiling Sulphur on Copper

By Carle R. Hayward

THE great affinity of sulphur for copper has long been a well-known fact. One of the experiments customarily used in elementary chemistry to show how two elements may be united to form a compound makes use of this affinity. Copper filings and sulphur are mixed together and heated in a test tube, causing the copper to be transformed into a sulphide. When several pounds of sulphide are desired for experimental purposes it is quite natural to mix copper and sulphur in a crucible and heat until fusion takes place, but the sulphide produced by this method usually does not some pure Cu_2S for evperimental purposes and found necessary to break up the mass, add more sulphur and fuse again.

Several years ago the writer had occasion to prepare some pure Cu_2S for experimental purposes and found a modification of the above method more satisfactory.[1]

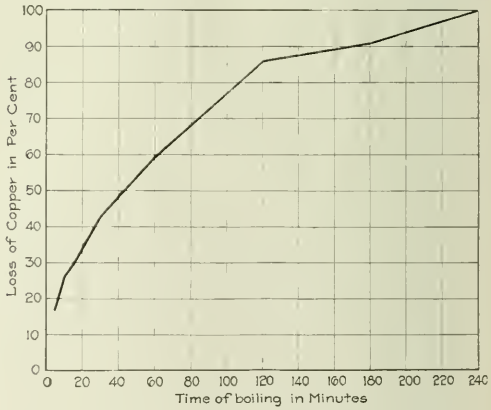

FIG. 1. AVERAGE PERCENTAGE LOSS OF COPPER

Some copper turnings were placed in a large casserole and boiled in sulphur for an hour. On pouring off the sulphur a porous mass remained composed of particles the shape of the original turnings but larger in size. No sign of metallic copper remained. In order to assure complete conversion to Cu_2S, the mass was removed from the casserole, mixed with 15 per cent sulphur and melted in a graphite crucible. After remaining molten for five hours the melt had the composition desired.

An attempt to produce nickel and iron sulphides by this method was unsuccessful. The shavings were practically unattacked by the sulphur.

The boiling of the shavings in the above case was continued for an hour but no attempt was made at the time to ascertain whether an hour was necessary or not. Recently tests have been made to determine the rate of penetration of boiling sulphur into copper and although the results may have no commercial value they bring out several interesting points.

[1] The Equilibrium Diagram of the System Cu_2S-Ni_3S_2. Trans. A. I. M. E., XLVIII, 141-52.

Rate of Penetration of Sulphur into Copper

The copper used in the experiments was in the form of hard-drawn rods ¾-inch in diameter. The rod was sawed into ¾-inch lengths, thus giving a cylinder the length of which was nearly twice as great as the diameter. The specimens were placed separately in iron crucibles containing boiling sulphur which was kept boiling for periods of time varying from five minutes to five hours. At the end of the treatment, the specimen was removed and the adhering sulphur allowed to burn off. The specimen was then weighed, after which it was broken open and the copper core remaining was weighed. The core dropped out when the specimen was broken and the surface was clean. In the specimens where no copper remained, there was a hollow space at the center of the shell. The boiled specimens were in all cases larger than the original and the edges were rounded off. The increase in diameter varied from $\frac{3}{32}$ inch in the five-minute specimen to ¼ inch in the four-hour specimen. The results are given in Table I.

TABLE I. ALL WEIGHTS IN GRAMS

Time Boiled	Weight Before	Weight After	Gain in Wt	Weight of Core	Loss of Copper	Per Cent. Loss Cu	Loss of Cu Gain in Wt

4 hr.	9 73	12 51	2 88		9 73	100 0	3 38
5 hr	9 82	12 85	3 03		9 82	100 0	3 24

The average results are given in Table II and the average percentage losses of Cu are plotted in Fig. 1.

TABLE II

Time Boiled	Gain in Weight of Sample	Loss in Weight of Cu	Per Cent. Loss of Copper	Ratio Av. Loss of Cu / Av. Gain in Wt
5 min.	0 60	1 95	12 2	3 25
10 min.	0 86	2 86	25 9	3 33
15 min.	1 00	3 39	29 5	3 39
30 min.	1 37	4 58	42 6	3 34
1 hr.	1 74	6 00	59 0	3 44
2 hr.	2 49	8 59	85 9	3 45
3 hr.	2 91	9 90	91 9	3 40
4 hr.	2 88	9 73	100 0	3 38
Average ratio				3 37

The gain in weight can be due only to the taking on of sulphur from the bath and it is fair to assume that this sulphur unites with the copper to form sulphide. It will be noticed, however, that the ratio of Cu to the gain in weight is in every case less than the ratio of Cu to S in Cu_2S which is 3.97. This indicates that the shell produced contains either elemental sulphur mechanically held or a higher compound of Cu and S.

Composition of the Sulphide Shell

In order to determine if possible the exact composition of the sulphide shell, one specimen from each period of boiling was pulverized, washed in CS_2 and analyzed for Cu. The results are shown in Table III.

It is seen from Table III that there is a slight tendency toward a lower copper content as the time of boiling is increased, but with the exception of the

TABLE III

Time Boiled	Cu	S	Per Cent. Cu
5 min.	78 12	2 1	77 24
10 min.	77 98	2 1	77 14
15 min.	78	4 1	77 37
30 min.	77		
1 hr.	77 72		77 58

five-minute specimen there is only a difference of 0.38 per cent of copper between the highest and lowest figures so it is possible that the product has in reality the same composition in each case.

The average analysis of the specimens is 77.58 Cu, giving a ratio of Cu to S of 3.42, which is slightly larger than the ratio between the average loss in weight of the copper core and the average gain in weight of the boiled specimen (See Table II).

Several of the specimens were examined under the microscope and revealed traces of CuS near the edge of the section. It seems probable, therefore, that the CuS acts as a carrier of sulphur from the bath to the metal.

The formula which most nearly corresponds to the composition of the material obtained is $5Cu_2S.2CuS$, which contains 77.31 per cent copper.

The results may prove of interest to the geologist in studying the formation of covelite and chalcocite or may have a bearing on the phenomena in kernel roasting.

Massachusetts Institute of Technology

Mining Engineers Drop Enemy Aliens

At a meeting of the Board of Directors of the American Institute of Mining Engineers held Wednesday evening, May 29, important resolutions were passed affecting enemy alien members of the Institute. The first resolutions proposed were modified to more nearly meet the approval of the directors present and the following were finally adopted after considerable discussion during which strong views were presented both for and against the proposal. In their final form these resolutions will scarcely find objectors among Institute members:

"Resolved, That all honorary members, members, associate, and junior members who are enemy aliens, residing in enemy countries, be dropped from membership in the American Institute of Mining Engineers, and their names be, and they are, stricken from the rolls.

"Resolved, That the Membership Committee be requested to advise this Board of Directors of the names of all the above mentioned persons, and in addition the names of all other enemy aliens, members of the Institute, and be it further

"Resolved, That, in the case of said latter class, this Board shall consider and act upon the question of expulsion after ascertaining their attitude toward the Government of the United States."

The action of the Board of Directors will affect immediately 21 Germans and 1 Austrian who hold either honorary or active membership in the Association. A thorough census will be taken of all other enemy alien members with a view to ascertaining their loyalty to the United States.

Synopsis of Recent Metallurgical and Chemical Literature

Viscosity of Blast-Furnace Slags.—Very important work from a theoretical and practical standpoint on the viscosity of iron blast furnace slags has been completed at the Pittsburgh station of the Bureau of Mines by A. L. FEILD and associates. A description of the problem and methods of solution was published by Mr. Feild in the *Transactions* of the Faraday Society, 1917, Vol. 13, part I, while recent *Bulletins* of the American Institute of Mining Engineers contain abstracts of Bureau of Mines *Technical Paper* No. 189, containing a record of the scientific data obtained, and of Bureau of Mines *Technical Paper* No. 187 on "Slag Viscosity Tables for Blast Furnace Work."

Silicates in general pass from a solid to a mobile liquid by a series of imperceptible steps. Lacking the characteristic of the sharp melting points of a pure compound, many determinations of the "softening" temperature have been made, wherein the deformation of a cone-shaped sample was observed. This "softening" temperature, according to Mellor, is that temperature where the inward surface pressure overcomes those intermolecular forces preventing an orientation conforming to the minimum surface of stable equilibrium. The softening of cones is therefore the resultant of the viscosity decrease, the action of surface forces, and the action of gravity. In general, the softening of silicates depends upon the amount of eutectic present; if a large amount of fusible eutectic is contained in the solid, softening may easily occur at a low temperature even when the viscosity of the fused portion is high.

The studies in viscosity described in these papers were made in a modified Margules apparatus (See METALLURGICAL AND CHEMICAL ENGINEERING, Vol. 15, page 541). The powdered slags were placed in a crucible made of 1½-inch round graphite electrode, bored ¾ inch (diameter = b) 3 inches deep, and heated in an improved "gran-annular" furnace. This furnace was surrounded with a tight iron casing, and an atmosphere of CO+N maintained. Into the slag was immersed a ½-inch (diameter = a) graphite cylinder, hung from a balanced astatic spring-suspension. On being rotated slowly at an angular velocity w the viscosity of the slag caused a measured couple c in the inner cylinder suspension which is related to the viscosity n as follows:

$$C = 4\pi nL \frac{a^2 b^2}{b^2 - a^2} w$$

where L is the common length of the two cylinders, disregarding end effect. Viscosity determinations were thus made at intervals during a regular heating and cooling cycle, the upper limit being the temperature resisted by the lundum furnace cores, and the lower the strength of the inner-cylinder suspension. Thirty-six viscosity tables are given in *Technical Paper* 187 covering all commercial iron blast furnace slags figured on the basis of $CaO+SiO_2+Al_2O_3 = 100\%$, covering each even per cent of alumina from 7 to 24, and their use explained by reference to specific problems in blast furnace practice.

The determined data indicate that the compounds which are stable in solid slags, (for instance: gehlenite and calcium metasilicate), do not decompose thermally into their constituent oxides on melting, for the following reason: The temperature-viscosity curve of the slag represented by Rankin and Wright's quintuple point 2 (see *American Journal of Science*, Vol. 39, page 1), was determined over a viscosity range from 100 to 2000 and yielded an equation between temperature T and fluidity f (fluidity is the reciprocal of viscosity) as follows, correct to plus or minus 5.5 deg. C.

$$T = 1167 + 7.37\ f - 4.45\ f^2$$

if this equation may be extrapolated from $f = .0005$ to $f = 0$, it shows that 1167 deg. C. is the temperature where viscosity becomes infinite, which, by the way, is Maxwell's criterion of the solid state. Rankin and Wright determine the melting point at 1170 deg. C. plus or minus 5, by noting the change in optical properties from the crystalline to the amorphous state. If therefore, the melting point of a mixture of compounds can be thus predicted from the behavior in the fluid state, the compounds certainly do not dissociate immediately or discontinuously on melting.

Such considerations affect the conceptions of slag action such as desulphurization. At slag forming temperature the sulphur (mostly introduced as coke ash) is almost entirely in the iron. The reaction generally given to cover its transfer to the slag is

$$FeS + CaO = CaS + FeO$$

with the following side reaction

$$FeO + C = CO + Fe$$

the two ordinarily combined as

$$FeS + CaO + C = CO + Fe + CaS$$

This latter reaction is now seen to depend upon the hypothetical thermal dissociation

$$Ca_2Al_2SiO_7 = CaSiO_3 + CaAl_2O_4$$
$$CaSiO_3 = CaO + SiO_2$$
$$CaAl_2O_4 = CaO + Al_2O_3$$

The final distribution of sulphur therefore depends upon the equilibrium constants of the last four equations. Disulphurization cannot simply be expressed in terms of the per cent of CaO in the slag, nor even worked out from Nernst's distribution law and the law of mass action if applied to the uppermost reaction only.

The reactions of desulphurization take place at the iron: slag interface, and the CaS formed there must diffuse into the slag at a speed high enough so that the reaction may continue until it reaches an approximation of the equilibrium ratio between sulphur in the iron and slag in the limited time available. A high hearth temperature which will promote fluidity and thermal dissociation of a properly constituted slag will promote desulphurization, provided the slag viscosity is not so low as to release its trapped iron globules too quickly. The reduction of silicon never approaches equilibrium, and the amount of silicon in the metal is therefore independent of the slag viscosity, *per se*. Consequently, high temperature, long contact, or both, favors a high silicon, low sulphur foundry iron. A moderate temperature and moderate time in contact produces low silicon and moderate sulphur, as does also a high temperature and short time of contact. These conditions are present in the furnace when making basic

iron, either with a very basic slag and a light burden, or with a somewhat basic slag and a heavy burden.

Since the composition of a blast furnace slag determines the rate of change of the temperature-viscosity curve, it determines the temperature of the smelting zone at a given rate of driving, and the length of time the iron is in intimate contact with the slag. The intelligent use of such relations would therefore reduce the losses in off-grade pig, improve fuel economy, promote operating efficiency, and extend present practice to cover lean and complex ores. Furthermore, since the radius of iron globules in contact with the slag approximates a constant quantity under operating conditions, the loss of metallic iron in slag should be directly proportional to the viscosity of the slag at the hearth temperature and to the rate of pig production.

Physical Constants of Ammonia.—NATHAN S. OSBORNE and M. S. VAN DUSEN have given the results of recent researches on the physical constants of ammonia in Bureau of Standards *Scientific Papers* Nos. 313, 314, and 315. The specific heat of saturated liquid ammonia was determined by two independent methods, using calorimeters specially adapted for the work, and an empirical equation devised which expresses the experimental results to within one part per thousand. The specific heat σ in joules per gram per degree centigrade, of liquid ammonia, kept saturated, at the temperature θ, is given in the range —45° to + 45° C, by the equation

$$\sigma = 3.1365 - 0.00057\theta + \frac{16.842}{133 - \theta}$$

The latent heat of vaporization was also determined and the following equation derived with the same degree of accuracy: The latent heat of vaporization of ammonia, that is, the heat required to convert saturated liquid into saturated vapor at constant temperature, in joules per gram, is expressed for the range -42 to -52 deg. C. by the equation:

$$L = 137.91 + 133 - \theta - 2.166\ (133 - \theta)$$

If the latent heat of vaporization is expressed in calories$_{20}$ per gram, taking 1 calorie$_{20}$ = 4.183 joules, the equation becomes

$$L = 32.968 + 133 - \theta - 0.5895\ (133 - \theta)$$

The transformation of energy into heat or vice versa, resulting from a change in pressure in liquid ammonia has also been determined by three independent methods, and tabulations for the range — 40 to + 40 deg. C. are presented.

Fine Grinding at Inspiration, Miami, and Anaconda.—Criticizing Mr. C. T. Van Winkle's paper on "Recent Tests of Ball Mill Crushing", E. H. KENNARD, who conducted the Inspiration tests for Mr. Hardinge, called attention to the close and expert attention necessary for a ball mill and ascribes the excellent performance of the Marcy mill to the experience in its handling gained by the operators in two years' practice, and the poorer production of the Hardinge type to improper location and defective arrangements for handling the pulp. The table of relative performance is also claimed to be misleading in that it is merely the record of a single day's run.

A. E. WIGGIN, superintendent of concentration for the Anaconda Copper Mining Company, said that previous to remodeling the Washoe concentrator a Hardinge pebble mill of 10-ft. diameter and 4-ft. cylinder was tested in comparison with an 8- x 12-ft. Power and Mining Machinery Co. tube mill, using pebbles and having a trunnion discharge. The results showed the Hardinge mill to be slightly superior, but he always considered the trunnion-discharge tube-mill and the Hardinge mill to be on a par as regards efficiency and costs of fine crushing. As they were obliged to order mills to remodel the entire concentrator without waiting the results of any more testing, and as they had experienced much mechanical difficulty and delay in deliveries with the tube-mill, it was decided to order Hardinge mills, and they saw no good reason for ordering any other size than the one they had tested. Since they had few data as to the relative merits of iron-ball vs. pebble crushing, they figured tentatively that while for pebble-crushing eight 10- x 4-ft. mills using 150 horsepower each would be required per section, for ball-crushing the same amount of material it would require four or five mills lagged down to 8 ft. in diameter, and using considerable more power. A compromise of 6 mills and 225-horsepower motors was finally agreed upon. Changing the shape of the mill did not, in any way that they have been able to detect, increase the efficiency of the Hardinge mill. The one factor which was responsible for the great improvement in their crushing efficiency is the reduction in the speed of the mills. When these were converted into iron-ball mills, 7½ x 6 ft. in size, the speed was first maintained at the original 23 r.p.m. Tests were later made at lower speeds, and at the conclusion 15 r.p.m. was fixed as the most efficient speed for these mills. This diminished the power consumption from 215 to 140 horsepower per mill, or a total of 2250 horsepower, and the ball consumption from 4.5 to 3.25 lb. per ton crushed, totalling 13,500 lb. per day, and, of course a considerable saving in lining and general repairs. The tonnage crushed and the fineness of the crushing are unaffected, and the savings from the two items mentioned amounted to over $250,000 per year.

Tests of American and Foreign Chemical Glassware

Prior to the summer of 1914 the greater part of the chemical laboratory glassware used in this country was imported from Germany and Austria. The cutting off of imports from these countries caused a very serious shortage of glassware in this country, which is not yet entirely overcome. However, within the past two years a number of American manufacturers have increased their production of such ware.

In order to furnish to chemists information regarding such domestic brands, it was decided by the United States Bureau of Standards to compare them with those of foreign make. These results of the bureau's tests indicate that all of the American-made wares tested are superior to Kavalier and equal or superior to Jena ware for general chemical laboratory use. Results of these tests are given in Technologic Paper, No. 107, "Comparative Tests of Chemical Glassware," which may be obtained from the Superintendent of Documents, Government Printing Office, for 10 cents.

Recent Metallurgical and Chemical Patents

Continuous Zinc Smelter. — A continuous zinc smelter has been patented by WOOLSEY MCA. JOHNSON, of Hartford, Conn., illustrated in Fig. 1, and consisting essentially of a continuous complex retort heated at the receiving end by ordinary fuel, and by electricity at the fusion end, provision being made for the recovery of various products according to the temperature of their evolution. Pre-roasted ore, containing more than the usual amount of sulphur left in zinc ore designed for retort smelting, is mixed with a suitable amount of coal, preferably of a sort involving enough volatiles to create a draft in the pre-heating operations and the mixture is introduced into the proper hearth 5. The ore is rabbled from each hearth to the next lower, and continuously subjected to a temperature of about 1050 deg. C., which is maintained by the conduction of heat through the retort walls from hot furnace gases circulating from the fireplace A through the passageways enveloping the pre-heating hearths. During this passage considerable sponge iron is formed, practically all the cadmium is evolved, and the ore is finally fed into the electric smelting furnace continuously through the downtake 30. Here the charge is smelted at a high temperature, the liquid portion being tapped at intervals and separated into metallic iron, molten matte, and a slag, while the zinc is volatilized, led into the condenser 43 and eventually drawn off and cast into bars from spout 45. (1,244,504, Oct. 30, 1917.)

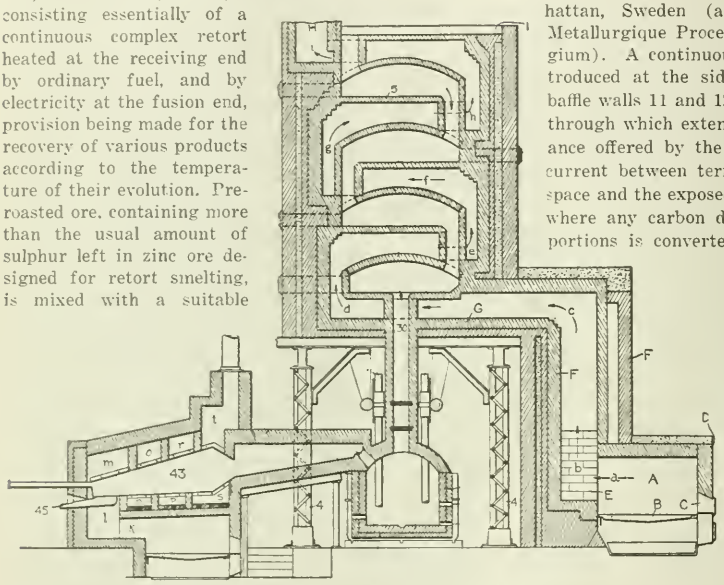

FIG. 1. JOHNSON CONTINUOUS ZINC SMELTER

Electric Furnaces for Zinc Reduction.—The method of extracting zinc from ores illustrated by means of Fig. 2 is patented by E. A. JOHANSSON, of Trollhattan, Sweden (assigned to Société Anonyme Metallurgique Procedes de Laval, of Brussels, Belgium). A continuous supply of cold charge is introduced at the sides of the furnace behind the baffle walls 11 and 12, which enclose a vacant space through which extends the electrode 2. The resistance offered by the charge to the passage of the current between terminals heats the entire vacant space and the exposed surface of the heap to a point where any carbon dioxide generated in the cooler portions is converted to monoxide on passing out through the heated surface. (1,256,802, Feb. 19, 1913.) FILIP THARALDSEN, of Christiania, Norway, observes that in smelting any heap of ore as mentioned in the preceding, the reduction and melting does not take place evenly over the surface of the heap as intended, but the localized action of the arc will eat cavities into the charge, the walls of which will eventually collapse, with the formation of quantities of undesirable dust. He therefore proposes the furnace sketched in Fig. 3, where a heap of ore charged into auxiliary chamber *b* at the left is struck out into a flat sheet by the movement of the car-body-hearth, and this flat sheet of ore smelted by radiation from a bare arc in the central chamber *a*. As the movement of the car proceeds to the right, the smelted residue is removed by the rake *k* as it enters chamber *b*. As the first charge is exhausted, a new portion of ore is dropped into the right hand chamber *b*, the movement of the hearth reversed, and the process continued as before. (1,255,066, Jan. 29, 1918.)

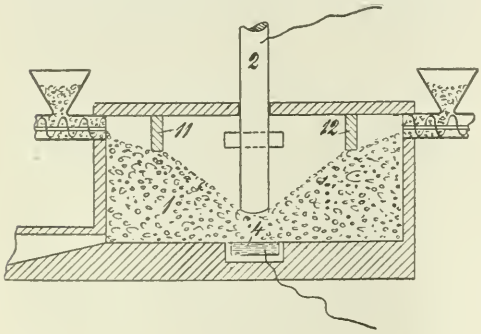

FIG. 2. JOHANSSON ELECTRIC ZINC FURNACE

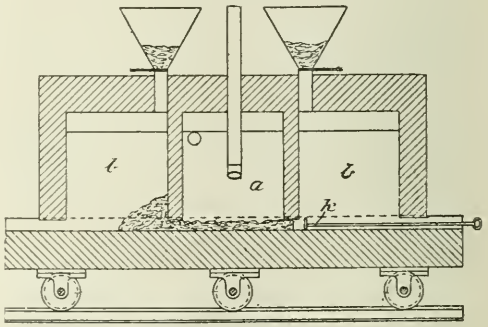

FIG. 3. THARALDSEN ELECTRIC ZINC FURNACE

Tiering in Freight Cars

TO UTILIZE all the storage space in freight cars is now a Government necessity and the piling of material that is required. At the same time, labor is so scarce

MACHINE FOR TIERING GOODS IN FREIGHT CARS

that concerns shipping heavy goods, such as rolls of paper, cases, bales, crated machinery, etc., are having difficulty in getting this work done. For this purpose the Revolvator Co., of Jersey City, N. J., has developed a portable tiering machine. By means of this machine one or two men can pile the goods clear to the roof of the car. The illustration shows one man tiering a 1000 lb. bale of waste inside a freight car. Without the machine, at least four men would be required.

New Design of Sextuple Effect Evaporator

THOSE who have to deal with the distilling of sea or other water or with evaporation problems in general kind, will be interested in a design of Lillie evaporator now being built by the Wheeler Condenser & Engineering Co., of Carteret, N. J. It is a modification of a regular Lillie sextuple effect sea-water distilling apparatus. Two of these now under construction are to be operated by steam up to 60 lb. per sq.in. gauge pressure, or at any lower pressure.

Four condensers, side by side, are employed as shown in the illustration.

This arrangement of condensers permits seven different combinations of operation, as follows:

1. It may be operated as one single effect or more single effects;

2. It may be operated as one or more double effects, with vapors reversible in each;

3. It is possible to operate it as a triple effect, or as two triple effects, with vapors reversible in each;

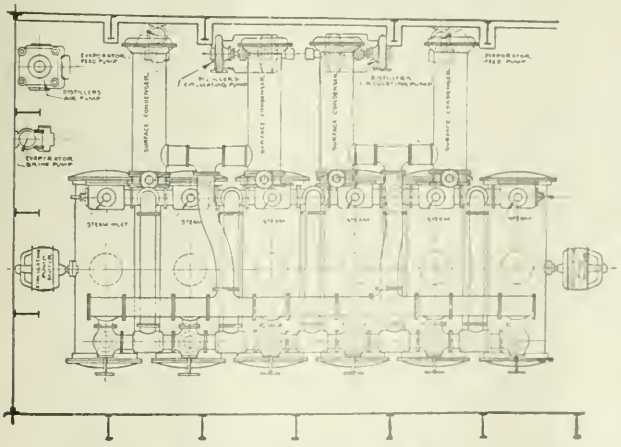
4. It is impossible to operate it as two quardruple effects, but every effect may be utilized by grouping as one quadruple effect and one double effect, in both of which the vapors are reversible;

5. It may be operated as one vapor reversible quadruple effect with both end effects or either end pair of the section cut out;

6. With one effect at either end cut out, it may be operated as a vapor reversible quintuple effect.

7. Lastly, it may be operated as a vapor reversible sextuple effect.

It is evident that should a mishap occur at either end, in the middle, or anywhere else, there is little danger that this evaporator will be put out of commission entirely.



SEXTUPLE EFFECT EVAPORATOR

Enemy Piracy of Trade Marks

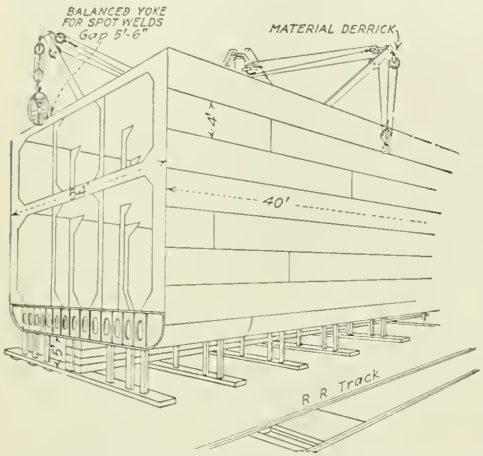
Our attention has been directed by Dr. L. H. Bakeland of the Naval Consulting Board to a new form of enemy piracy relating to trade marks of American manufacturers. Certain countries recognize the first to register a trade mark as the rightful owner and hold that the subject is not open to further discussion. Argentina, Brazil and Chile are among those in which the rule prevails.

There is also a Trade Mark Convention among the following countries with headquarters at Berne: Austria, Belgium, Brazil, Cuba, Spain, France, Hungary, Italy, Mexico, Holland, Portugal, Switzerland and Tunis. On payment of a fee of 100 francs to the central bureau by any member of the Convention, the ownership of a trade-mark is registered in all 13 countries. Austrian firms have been active in this respect and as an example, Mr. Richard Mittler of 6 Wiesingerstrasse, Vienna, has registered as his, Ajax, Federal, Firestone, Fisk and Republic automobile tires, unless the actual owners were there before him. Additional instances are known of the registration by a German, formerly resident in Belgium, of the names of three well-known American typewriters, of Jap Rose Soap, Foos Gas Engines and the Waukegan mark of the American Steel and Wire Co.

The State Department has the matter in hand. American manufacturers are urged to register their trademarks in other than enemy countries without delay.

Test of Electric Welding for Steel Ships

THE purposes and possible benefits of the ship welding test now being conducted at the Federal Shipbuilding Company plant at Newark, N. J., are outlined in a report by Arthur J. Mason, vice-president of the corporation. We quote in part from the report as follows: Electric welding in its various phases has for years been employed in shipyards and in the arts generally, but for a number of reasons the work has been confined to odd jobs and repairs. The proposal to extend its use to the major part of ship construction has met with gratifying approval from the shipbuilder. It remains for us through this large test to demonstrate its economy in time and money and its adequacy to build a stanch ship.



PART OF SHIP'S HULL THE PLATES OF WHICH ARE BEING JOINED PARTLY BY RIVETING AND PARTLY BY WELDING

The purpose of this test is to demonstrate these advantages—to do it in such a way that all may see and contribute, and finally to test the structure itself so completely that there will follow a heart-whole and unanimous belief in the method.

The test itself will take the form of building part of a hull at the Federal Shipbuilding Company's plant, Newark, N. J.

A 10,000-ton ship, costing $2,000,000, now costs but $70,000 to rivet. It must be plain that if electric welding only promises to modify this amount no very substantial gain offers.

Splendid benefits we all feel do offer themselves in the possible change in the whole regime of shipbuilding. Our test has in view abolishing, or greatly diminishing:

1. The railroad journey from rolling mill to fabricating plant, when the latter is not at the shipyard.
2. The templet makers' work.
3. The makers' work.
4. The punching.
5. Much of the work of fitters and bolters who flog and pull the pieces to fit on the ways. There lies in the above items an excellent likelihood to save a month's time in construction and a saving of no less than $40 a ton in the cost of steel structure, at least $100,000 a hull on a 10,000-ton vessel.

Briefly the program is to assemble a hull rapidly by spot welding, tacking the ship together much as a tailor bastes his work in assembling a suit of clothes. The structure then becomes a house favorable for work in all weather and at night in which the completion of the ship may go on.

After the material is thus assembled and fastened with spot welds, so that it is sufficiently strong to hold its shape, the work is completed by arc welding all seams to insure strength and render the work watertight. Roughly we expect the spot welds to be about 10 in. (25.4 cm.) apart.

One-quarter of the structure will be riveted, the other three-fourths welded, so that the tests of strength will afford a basis of comparison.

Electric welding offers a great field for lightening a ship. In this design various views of this opportunity will be tried out. The field here is very great —ultimately 10 per cent of the steel may be eliminated.

One derrick will bring material, the other derrick support the spot-welding yoke, whose function is to tack the material together, fastening the plates either to the frames or to the adjoining plates.

The problems of fitting in place the parts of a hull are almost wholly problems arising out of the necessity to make a number of little holes in a plate made by one man at one time and place fit a number of little holes made by another man at another time and another place.

Once all holes are left out of the material, all parts fit. The creeping and kindred problems so perplexing to the shipbuilder disappear. Every plate becomes a closer. Every plate justifies itself.

The manufacture of the spot-welding yoke and appliances is placed in the hands of the Universal Electric Welding Company of Long Island City. The design of the yoke is completed, the patterns are made and steel castings will be forthcoming in the next ten days. The early stages of the arc welding are to be accomplished by the Wilson Electric Company, which was so successful in the work on the German ships' repairs, but it is the intention to call in all men with ideas and apparatus and to give them a field to test out in actual work. To this end Professor Adams' committee is searching out all available talent.

An adequate system of testing the work when done is under consideration. The primary test will consist of filling the hull with water and shifting the points of support under continual and close scrutiny, as one-quarter of the whole will be riveted in the normal manner. There will be always a gage of comparison with that portion which is welded.

Likewise there will be a chance for comparison of the two forms when subjected to abuse by bumping with rams and in various other ways.

Lord Reading, British Ambassador, while inspecting the Hog Island shipyard with Charles M. Schwab, where an 8500-ton freighter is to be finished every 48 hours, said: "Give us ships like this and we will win the war even should the Germans reach the Channel Ports or Paris."

Book Reviews

METHODS FOR TECHNICAL SAMPLING AND ANALYSIS OF GASES. Copyright 1918 by *J. M. Camp*, Chairman Chemists' Committee, United States Steel Corporation, Pittsburgh.

This revised second edition of the pamphlet on gas analysis has been prepared by a committee of chemists from several of the plants of the U. S. Steel Corporation. Like the first edition it is an example of the technical benefits resulting from bringing into one large organization a number of separate units with their combined experience and knowledge. It is doubtful whether a better set of technical methods of gas analysis could be compiled.

This is very similar to the first edition (reprinted in METALLURGICAL AND CHEMICAL ENGINEERING, Vol. IX, pp. 302 and 356). Additions have been made to the text in the way of a method for the analysis of by-product gas, as nearly as possible like that already published for producer and blast-furnace gases, with methods for the determination of its content of benzol, total sulphur, and cyanogen. A method for the analysis of natural gas has been incorporated that differs slightly from that given for other fuel gases in that larger quantities for explosion are employed. This feature of the method is of decided advantage, because no error is introduced by a high percentage of resulting carbon dioxide. Elementary calculations of thermal values, specific gravity, and air necessary for combustion are explained and illustrated.

This series of pamphlets, which also includes publications on the sampling and analysis of iron ore, pig iron, steels and coal, coke and by-products, forms a most valuable critical compilation of useful methods based on extended research and wide experience.

POWDERED COAL AS A FUEL. By *C. F. Herington.* 211 pages, price $3.00 net. New York, D. Van Nostrand Co.

The author collected the material for this book while asistant engineer of the New York Central Railroad Co. The historical notices consist largely of patent abstracts, the descriptions of machinery seem to be taken from manufacturers catalogues, while the chapters relating to the application of powdered coal to various industries are lifted largely from published literature. For instance, Chapter VI, on the application of powdered coal to reverberatory furnaces consists of the two papers by David H. Browne of the International Nickel Co. and Louis V. Bender of the Anaconda Copper Mining Co., presented before the February, 1915, meeting of the American Institute of Mining Engineers. Even the well illustrated chapter on powdered coal for locomotives, where the author presumably has had experience and could speak with authority, is apparently an abstract of J. E. Muhlfeld's paper before the December, 1916, meeting of the American Society of Mechanical Engineers. Elsewhere H. Barnhurst's papers before the Mining Engineers and in this journal, and A. S. Mann's experiments published in the General Electric Review are also quoted very extensively. A bibliography compiled by the Engineering Societies' Library is uncollected as to author, publication, date, subject matter and language.

In the introductory part the author presents estimates of the cost of construction and operation of various comparable systems, showing a great advantage accruing to the Holbeck system. In this the coal is transferred in suspension in air in a closed circuit from the storage bin, through the furnace rooms, and back again, returning the unburned fuel to the starting point. Mr. Herington notes that the most recent developments have been made in utilizing very low grade fuels, such as anthracite culm, and that the amount of ash in the combustible, up to 33 per cent, is not of as great importance in most practices as is whether it produces a "soft" undesirable clinker, or a "hard" brittle clinker giving a light, fluffy ash and little trouble.

The book collects a considerable amount of information as to the proper separation of air from the coal after pulverizing, and as to the proper mixing of air and coal before and during burning. As to the many designs of burners which have been introduced or patented, he quotes the words, "Any mechanism which will give a uniform mixture of coal and air with both under control can be used as a burner for powdered coal."

* * *

METALLURGICAL CALCULATIONS. By *Joseph W. Richards.* One Volume edition, octavo, xxiii + 675 pages. Price $5.00. New York: McGraw-Hill Book Company, Inc. London: Hill Publishing Co., Ltd.

Many users of Dr. Richard's "Calculations" will be pleased to know that a one-volume edition has been issued. Part I, as incorporated herein, has been considerably revised and brought up to date. The separate parts are still obtainable, for the use of students and technologists.

Published originally as a serial in Metallurgical and Chemical Engineering, this treatise on quantitative metallurgy has earned for itself an international reputation; it has in numberless cases pointed the way to a deeper understanding of metallurgical processes and to higher metallurgical efficiency. It has struck the keynote of metallurgical progress in the Twentieth Century.

* * *

STEEL AND ITS HEAT TREATMENT. By *Dennison K. Bullens*, Consulting Metallurgist. Octavo, 483 pages, 285 illustrations; price, $4.00 net. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd.

This is a second edition of an excellent treatise reviewed in our issue of July 15, 1916. That the book has met with a wide demand is evidenced by the early exhaustion of the first and second impression. In the third printing, the author has availed himself of the opportunity of a thorough-going revision of the text, enabling him to correct many of the errors of omission and commission noted in our earlier review.

Mr. Bullens is to be highly commended for introducing a great deal of matter in his new edition regarding the influence of the human element in heat treatment. He calls attention to the fact that the heat treater is the chef that puts the metallurgical finish on material prepared at great expense by others, and it is his skill and exercise of judgment that determines the final result which either makes or breaks the operation. In many cases the installation of pyrometric equipment merely results that the operator in effect is doing nothing more than manufacturing record charts, instead of properly heating his steel. Good steel is entitled to proper treatment in good furnaces, and both are entitled to the services of good men to produce good results; the best men available are none to good for such important work. Not only is this true, but the strongest language that could be employed to describe the general average heat-treatment equipment, the methods of heating and personnel as they are actually known to exist, would be altogether too mild and ineffective for a proper description of the heating methods and equipment in the majority of forge shops in the country. The apparent advantages of the motor truck were not side-tracked by the fact that it was necessary to teach men how to operate them, and yet there is just as much if not more reason why men, and if necessary a different type of man, should not be taught how properly to heat steel.

* * *

DISEASES OF OCCUPATION AND VOCATIONAL HYGIENE. Edited by *Geo. M. Kober*, M. D., LL. D., and *Wm. C. Hanson*, M. D., aided by 29 Specialists. Octavo (23 x 15 cm.), xxi + 918 pages, 46 illustrations. Price $8.00. Philadelphia: P. Blackiston's Son & Co.

It would be difficult to praise this book too highly. It is written not only to describe Specific and Systemic Diseases of Occupation to medical and legal experts, medical examiners, insurance examiners, practising physicians, teachers, lawyers, students, but also to treat of the Causation and Prevention of such diseases, for the benefit of employers,

employees, public health officials, nurses, social workers, legislators and teachers. The editors themselves wrote most of the chapters on Causation and Prevention, and they are most excellently written. Twenty-two pages on the iron and steel industries, twenty-four on mining and quarrying, seventeen on food industries, thirteen on brass, copper and zinc industries, are examples of the thoroughness of the treatment. The chapters on history, legislation, statistics, etc., are very well written. The book should be found in every industrial plant, and should be well-studied and its teachings closely followed.

Personal

Mr. JULIUS ALSBERG announces the opening of his metallurgical and chemical engineering consulting offices in the Tribune Building, Chicago.

Mr. D. W. BRUNTON of Colorado has been elected a member of the Naval Consulting Board.

Mr. P. B. CHILLAS, Jr., formerly in the Research Laboratory of the National Carbon Co., Inc., is now at the Frankford plant of the Barrett Company, Philadelphia.

ENGINEERING FOUNDATION BOARD has elected the following to membership: Mr. CALVERT TOWNLEY, Westinghouse Electric Mfg. Co.; Mr. SILAS H. WOODWARD, M. Am. Soc.; Dr. JOSEPH W. RICHARDS, Lehigh Metallurgy Dept.; Dr. DAVID S. JACOBUS, Babcock & Wilcox; Mr. H. HOBARD PORTER, Sanderson & Power.

Mr. WOOLSEY MCA. JOHNSON married Miss KATHRYN VERONICA O'HARA, daughter of Mr. and Mrs. W. S. O'HARA of Philadelphia. The couple are now at Washington but later will reside at Cynwyd, Pa.

KENNETH DESPRES KAHN, research metallurgist of Cleveland Brass Manufacturing Co., Cleveland, O., is assistant chemical engineer, division of small scale manufacturing of war chemicals, American University, Experiment Station, Bureau of Mines, Washington, D. C.

Mr. A. LINCOLN KONWISER, formerly superintendent of the Hygiene Chem. Co. at Elizabethport, N. J., and until recently connected with the chrome plant of the Metals and Thermit Corporation, has been appointed factory superintendent and chemical engineer for J. S. & W. R. Eakins, Inc., Brooklyn, N. Y.

Mr. WM. R. LAFFERTY, formerly chemist at the Camden and Bayonne Works of the General Chemical Co., has recently become assistant superintendent at the Bridesburgh, Pa., factory of Charles Lenning & Co.

Mr. WM. A. LEWIS has closed his plant at Monroe and Ferry Sts., Hoboken, N. J., having enlisted in the U. S. Naval Reserves.

FRANK K. MARVIN, formerly Chief Chemist of the Howard Smokeless Powder Co. plant and Aetna Research Laboratory at Emporium, Penn., has been appointed explosives chemist of the Bureau of Mines and stationed at Pittsburgh, Pa.

Mr. E. P. MATHEWSON, who has been with the Anaconda Copper Co., then the British American Nickel Corporation, recently returned to the American Smelting & Refining Co. as consulting metallurgist. He will be at the New York office of the latter company.

Mr. FREDERICK J. MAYWALD has shifted his office and laboratory so that the other entrance of the building at 133 Water Street must be used when entering to consult him.

Mr. JAMES H. READIO, JR., has left the Pawtucket Gas Works to become assistant chemical engineer with the Providence Gas Co.

Prof. G. A. ROUSH of Lehigh University has been appointed supervisor of training, Inspection Division, Ordnance Department. He will have charge of the training of inspectors, recently inaugurated by the War Department.

Mr. FOREST RUTHERFORD, consulting metallurgist, New York City, has been appointed a member of the advisory committee in non-ferrous metals to the U. S. Tariff Commission.

Mr. A. GORDON SPENCER, consulting chemist and metallurgist, Montreal, P. Q., has given up his practice to devote all his time to metallurgical work for Peter Lyall & Sons Construction Co., manufacturers of munitions.

Mr. ROGER TAYLOR has been assigned to the Ordnance Reserve Corps and has therefore severed his connection with the engineering firm of Frederick deP. Hone & Co., New York.

Mr. JOEL H. WATKINS, formerly economic geologist for the Southern Railway, has opened consulting offices at 200 Fifth Avenue, New York, where he will give special attention to the mineral resources of the Appalachian region.

Mr. A. E. WIGGIN has been appointed general superintendent of the Boston & Montana reduction department of the Anaconda Copper Mining Co.

Current Market Reports

Non-Ferrous Metal Market

Friday, June 7.—Prices are tending to be better controlled by the Government. Copper and manganese prices are fixed by law; lead is advancing; tin has fluctuated due to abnormal shipping.

Aluminium.—Government advanced the rate to 33c.

Antimony.—The Government was in the market for 250 tons for July. We quote spot at 12¼ @ 12¾c. futures at 11¼c. c.i.f. in bond.

Chrome.—Producers have established a schedule on the basis of $1.30 per unit ore.

Copper.—War industries board set prices at 23½c. until Aug. 15. Producers' meeting called for Aug. 7.

Lead.—There are widespread inquiries and negotiations for future deliveries, the disposition being to stock up. Prices have advanced to 7⅜c.

Manganese.—Price scale with silica and phosphorus penalties. Unit prices: 40 per cent $1.10, 50 per cent $1.20. See further report.

Molybdenum.—Quoted at $1.25 per lb. of 90 per cent molybdenum sulphide.

Smelter.—Market was stronger; business very light. Quoted at 7¼c. to 7½c.

Tin.—Varying prices. Chinese tin at San Francisco, 86c.; Straits tin, New York, $1.08 to $1.10.

Tungsten.—Scheelite is quoted at $24.00, Wolframite at $19. @ $24.00.

OTHER METALS

The Iron and Steel Market

The distribution of pig iron and steel products, for some months to come if not for the duration of the war, was placed upon a clearly defined basis by the resolution of the War Industries Board, June 6. The actual distribution, however, is not greatly altered from the procedure that has obtained since the producers subscribed, at the close of April, to the pledge of 100 per cent efficiency for war work.

In order to explain briefly what has occurred it is desirable to adopt a nomenclature. One may define "war steel" as material that is ordered directly or indirectly by the government, for its own use or the use of its Allies, "commercial steel" being all other, irrespective of whether or not its employment is helpful towards winning the war. The nomenclature in comon use some time ago, classing industries as "essential" and "nonessential" became taboo in Washington some time ago, the preferable way of looking at the matter being to regard the industries as "more essential" and "less essential," though this is not good English.

For many months the war material has been under direct control of the War Industries Board through the medium of "priority certificates," but there is no precise definition of what classes of material may be the subject of such certificates. By the resolution of June 6 the War Industries Board recognizes three classes of material: (1) Material covered by its priority certificates, which are specific as to the tonnage and description of material involved in each certificate; (2) Material that is covered by a "schedule of purposes entitled to preference treatment" after the material covered by the priorities certificates is taken care of; (3) All other.

Class 2 is essentially the "more essential" material. It is to be distributed by the producers themselves, who are to ascertain from their customers the precise use intended for material furnished, and who are to report precisely each week the tonnages they have shipped, in detail. Hitherto they have reported specifically as to government order numbers, merely giving the total tonnage of all others.

Thus, as to the more essential uses, the War Industries Board prescribes precisely the uses, while the producers distribute the material as to actual tonnages to various customers. The distribution, in other words, is left in the hands of the producers, as they desired. Prior to the New York meeting of April 26 the War Industries Board had contemplated distributing this material also, perhaps by the same machinery of priority certificates as had been in use for war material.

Scope of Recognized Purposes

In form, it is a very drastic operation to cut off supplies of material to Class 3, when it embraces everything not covered by the two preceding classes, and when there is every prospect that there will be little if any material left to be distributed to Class 3. In actual fact, however, the tonnage requirements of Class 3 cannot be large, and material has been denied them almost entirely since the begining of May, and was quite largely denied them for months previously.

In actual fact, however, the deprivation is not great. Building of all descriptions falls in Class 3, unless it is in connection with either of the other classes, but as a matter of fact the building that fails to receive recognition has practically stopped already. There is scarcely any building except in connection with the war, yet in normal times building absorbs a very large part of the steel output. The largest single customer of the steel industry has been railroading, but not only railroads but also other means of transportation, including water transportation specifically mentioned, are named in the "schedule of purposes," while furthermore, since the railroads are under Federal control the specific lots of material required will doubtless be made the subject of priority certificates, and thus fall in the first class rather than the second.

The business of producing and transporting petroleum, and the business of mining coal have been large consumers of steel, but they are included in the schedule of purposes, as relating to fuel. The production and packing of food and the manufacture of clothing for the civilian population are likewise included.

After considering the circumstances referred to in the two preceding paragraphs, it is obvious that there is not much steel to be denied to anybody by reason of his receiving no recognition at Washington at this time. It must be considered further that the great war machine of the United States that is now getting into really powerful operation was not built from the ground up. It was not a case of building shipyards in their entirety, or shell factories, and recruiting them with men who were found outside the regular industries of the United States. Manufacturing facilities that had been always used for the fabrication or working up of iron and steel were largely employed, and thus both plant facilities and men have been diverted in their employment. Thus the normal consumption has largely disappeared in favor of the war consumption. One cannot erect a skyscraper, but the fabricating shops that ordinarily would take the order for the skeleton steel structure are busier than ever, making parts for fabricated ships.

While to individuals finding themselves in the "all other" or third class the dislocation will appear great, in point of tonnage the greatest shortage will be among those finding themselves in the second class, as there will hardly be enough steel to supply fully all their requirements.

Production

There is no material change in the rate of production, which in pig iron is running at between 41,000,000 and 42,000,000 tons a year, with supplies of coke very nearly adequate, and with much new by-product capacity in near prospect, but on the other hand with a period of a couple of months of high humidity facing the furnaces. If a rate of 41,000,000 tons a year is maintained over June, July and August reasonable expectations will have been met, although for a whole twelvemonth the capacity may be taken at not under 43,000,000 tons.

Production of ingots, relative to pig iron or finished rolled steel, is heavier than formerly by reason of the mills endeavoring to swell the production of war steel. This leads them to melt shell discard steel, sheet bar crops, etc., instead of rolling the material into merchantable form.

Prices

The existing set prices expire by limitation June 30 and before the end of the month the War Industries Board will take action on this matter. It is quite foreign to the board's views that there should be any price advances, unless in very special circumstances, and apparently its attitude at the end of March was that there ought to be reductions, but that such action could be deferred by reason of the furnaces and mills having had such poor operating conditions in January and February, so that they could have three months of good times to recoup. However, there was a wage advance of 15 per cent in April and the general advance in freight rates to become effective June 25 will amount to about $1.25 per ton in the manufacture of pig iron and about $2 a net ton in the manufacture of the average rolled steel product. Thus a general reduction in prices may be avoided. There will be no reduction unless the Federal Trade Commission finds the earnings have been running particularly large of late. The matter of large profits for taxation purposes hardly enters now, when the government is itself a very large buyer, but on the other hand the requirements are so large that it is more necessary than formerly to stimulate production to the last ton.

Chemical Market

Heavy Chemical:—During the past two weeks the movement in products under this classification has been rather more pronounced and quite a few more important transactions have transpired. Prices generally have ruled on a somewhat higher level and the tendency appears to be upward in most instances.

Caustic Soda:—The tendency of the market on this commodity has been toward a firm advance during the last two weeks and the trading has been quite active. The standard brands were being quoted at from $1.50 to $1.65 and in several instances $1.70 and $1.75 were spoken of. As to value there was a great difference of opinion in regard to prospects for the balance of the year or even for the next three months.

Soda Ash:—Since our last writing there has been a slight increase in activity accompanied by rising price demand. Against the quotations in our last issue of 2.60 and 2.70 for ash in barrels the offerings at this writing are 2.75 and 2.80 and from store there were a number of offers at from 2.90 to 2.95. Prices on bag material have also slightly advanced and the feeling is of a general underlying strength.

Sulphuric Acid:—The acid situation has developed some points of interest since our last report and the general opinion is that buyers will have difficulty in locating material from now on. The Government's requirements are becoming more pronounced and although there are interests that contend that acid in tanks can still be purchased at from $2.50 to $3.00 works, nevertheless they admit an increasing difficulty in obtaining offers from producers. Drum acid is reported to have sold as high as $55.00.

Oleum:—For twenty degree resale material there have been a few sellers at $55.00 tanks and $65.00 drums. The only producer of 60% material is reported as sold up.

Yellow Prussiate of Soda:—During the latter portion of the last two weeks period there has developed a slight depreciation in price as a result of more frequent offers and a lack of buying interest. Seventy cents was generally quoted although in one instance a possible buy at 68c was reported.

Bichromate of Soda:—Since our last writing which indicated an increasing inquiry interest with prices at 24½c and up to 25c the trend has continued upward and spot material is now held rather generally at from 26c to 26½c, for less than car quantities.

Copper Sulphate:—The inquiries for this product have continued active, quotations ranging around 9c. Many of the offers however undoubtedly are through second hands and have somewhat depressed the market to a slight degree as there developed possible purchases of standard brands of large crystals at 8.50.

COAL TAR PRODUCTS:—The demand for crudes is very quiet and the market in these products reflects considerable ease. Offerings are plentiful and there have been some declines in price registered. The intermediates are firm however and prices are quotably unchanged in most instances.

Benzol:—The market is very easy and offerings are reported of material at attractive prices. The consuming demand is very light and most sales have involved only small quantities.

Phenol:—The situation shows practically no change. The tone is easy with supplies of material continuing to be rather large. There are export inquiries reported that may absorb considerable material but up to the present the difficulty has been in the securing of export licenses for the War Trade Board.

Toluol:—Since the last report the Government through the Raw Materials Division of the War Trade Board has announced fixed prices for the release of toluol whether for non-military use or not. This action was taken in response to complaints from various sources that exorbitant prices were being paid by consumers in comparison with the price the government was paying. The established prices for original releases are 1.50 for large quantities and 1.55 for drums of any quantity. The market as far as real material is concerned shows no alteration and the business being transacted is very light. Releases being made to benzoate of soda producers do not seem to have benefited the resale situation at all.

Naphthalene:—Price declines have been noted and the market is confused with the liberal offerings being made of prime white flakes. Very attractive prices have been quoted for resale material. The ball material is also easier.

Benzoate of Soda:—There have been offerings at attractive prices recently but at the present time these appear to have been absorbed and a firmer appearance to the market is noted. The report has been circulated that the government will take over chlorine which may have added to the firmness which was experienced recently. The demand is fair.

Dimethylaniline:—Production continues to be confined to a few producers. There is fairly active demand and prices have held firm.

Paranitraniline:—Advances have been noted largely because of the acetic acid situation. The requirements of the market are said to be met with although production is confined to a few producers.

Aniline Oil:—With business of moderate proportions passing there is no change to record.

Beta Napthol:—The technical grade continues to be active. There is no change in the sublimed. The demand continues to be fair.

Alpha Napthylamine:—The easy tone evident in this product continues with fair business passing. The amount of supplies continues to meet present requirements.

Metatolumylenediamine:—The demand is unchanged and business of routine nature is passing. Prices show no change.

Paramidophenol:—With price levels unchanged there is a fair demand current.

Phthalic Anhydride:—Prices are firm. The demand is good and the trend seems to be upward.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JUNE 8, 1918

Acetic anhydride	lb.	1.50 — 1.60
Acetone, drums	lb.	Nominal
Acid, acetic, 28 per cent	lb.	Nominal
Acetic, 56 per cent	lb.	Nominal
Acetic, glacial, 99½ per cent., carboys	lb.	Nominal
Boric, crystals	lb.	.13½ — .14½
Citric, crystals	lb.	.85 — .87
Hydrochloric, C. P	lb.	Nominal
Hydrochloric, 20 deg	lb.	.02½ — .02¾
Hydrochloric, conc., 22 deg	lb.	.02¾ — .03
Hydrofluoric, 30 per cent., in barrels	lb.	.08 — .08½
Lactic, 44 per cent	lb.	15 — .15½
Lactic, 22 per cent	lb.	06 — .06½
Molybdic, 85 per cent	lb.	3 85 — ...
Nitric, 36 deg	lb.	Nominal
Nitric, 42 deg	lb.	.09 — .10
Oxalic, crystals	lb.	.43 — .45
Phosphoric, 47–50 per cent. paste	lb.	.08 — .10
Phosphoric, ref. 50 per cent	lb.	.26 — ....
Picric	lb.	Nominal
Pyrogallic, resublimed	lb.	3.10 — 3.15
Sulphuric, 60 deg	ton	Nominal
Sulphuric, 66 deg	ton	35 00 — 40 00
Sulphuric, oleum (Fuming), tank cars	ton	00 00 — 65 00
Tannic, U. S. P., bulk	lb.	1.30 — 1.35
Tartaric, crystals	lb.	.87 — .88
Tungstic, per lb. of W	lb.	1 70 — 1.75
Alcohol, sugar cane, 188 proof	gal.	4 93 — 4 95
Alcohol, wood, 95 per cent	gal.	.90½ — .91
Alcohol, denatured, 180 proof	gal.	.68 — .69
Alum, ammonia lump	lb.	.04 — .04½
Alum, chrome ammonium	lb.	.17½ — .18
Alum, chrome potassium	lb.	.20 — .21
Alum, chrome sodium	lb.	.12½ — .13
Alum, potash lump	lb.	.08½ — .09
Aluminium sulphate, technical	lb.	.02½ — .03
Aluminium sulphate, iron free	lb.	.03½ — .03¾
Ammonia aqua, 26 deg. carboys	lb.	(Fixed Price)
Ammonia, anhydrous	lb.	Nominal
Ammonium carbonate	lb.	Nominal
Ammonium nitrate	lb.	(Fixed Price) .15
Ammonium, sulphate domestic	lb.	.07¾ — .08
Amyl acetate	gal.	5.40 — 5.50
Arsenic, white	lb.	.09 — .16½
Arsenic, red	lb.	.60 — .70
Barium carbonate, 99 per cent	ton	80.00 — 90.00
Barium carbonate, 97–98 per cent	ton	65.00 — 67.00
Barium chloride	ton	85.00 — 85.00
Barium sulphate (Blanc Fixe, Dry)	lb.	.02½ — .02¾
Barium nitrate	lb.	.09¾ — .10
Barium peroxide, basis 70 per cent	lb.	.30 — .32
Bleaching powder, 35 per cent. chlorine	lb.	.01 — .02
Borax, crystals, sacks	lb.	.07¾ — .08¾
Brimstone, crude	ton	Nominal
Bromine, technical	lb.	.75 — ....
Calcium, acetate, crude	lb.	Nominal
Calcium, carbide	lb.	.16 — .16½
Calcium chloride, 70-75 per cent., fused, lump	ton	27.50 — 30.00
Calcium peroxide	lb.	1.60 — 1.70
Calcium phosphate	lb.	.34 — .35
Calcium sulphate, 98–99 per cent	lb.	.09 — .09½
Carbon bisulphide	lb.	.08¾ — .10
Carbon tetrachloride, drums	lb.	.15½ — .16
Carbonyl chloride (phosgene)	lb.	1.10 — 1.50
Caustic potash, 88-92 per cent	lb.	.81 — .83
Caustic soda, 76 per cent	100 lb.	4 60 — 5.00
Chlorine, liquid	lb.	(Fixed Price) .07½
Cobalt oxide	lb.	1 60 — 1.65
Copperas	lb.	.01½ — .01¾
Copper carbonate	lb.	.30 — .40
Copper cyanide	lb.	.75 — .78
Copper sulphate, 99 per cent., large crystals	lb.	.08¾ — .09
Cream of tartar, crystals	lb.	.65 — .85
Epsom salt, bags, U.S.P	lb.	.03¾ — .03¾
Formaldehyde, 40 per cent	lb.	.17½ — .18¾
Glauber's salt	100 lb.	1.50 — 1.75
Glycerine, bulk, C. P	lb.	.63 — .65
Iodine, resublimed	lb.	4 25 — 4.30
Iron oxide	lb.	.13 — .15
Lead, acetate, white crystals	lb.	.17 — .18
Lead, arsenate (Paste)	lb.	.15 — .18
Lead nitrate	lb.	Nominal
Litharge, American	lb.	.09½ — .10¼
Lithium carbonate	lb.	1 50 — 2.00
Manganese dioxide, U. S. P	lb.	.70 — .75
Magnesium carbonate, technical	lb.	15 — .16
Nickel salt, single	lb.	.14 — .15
Nickel salt, double	lb.	.12 — .14
Phosgene, see Carbonyl chloride		
Phosphorus, red	lb.	1.30 — 1.50
Phosphorus, yellow	lb.	1.25 — 1.40
Potassium bichromate	lb.	.44 — .46
Potassium bromide granular	lb.	1.35 — 1.50
Potassium carbonate, calcined, 85-90 per cent	lb.	.40 — .50
Potassium chlorate, crystals	lb.	.38 — .40
Potassium cyanide, 98-99 per cent	lb.	Nominal
Potassium iodide	lb.	3.75 — 3.80
Potassium muriate 80-85 p. c. basis of 80 p. c.	ton	325.00 — 350.00
Potassium nitrate	lb.	.27 — .31
Potassium permanganate (U. S. P.)	lb.	3.10 — 3.40
Potassium prussiate, red	lb.	2.80 — 2.90
Potassium prussiate, yellow	lb.	1.15 — 1.20
Potassium sulphate, 90-95 p. c. basis 90 p. c.	ton	Nominal
Rochelle salts	lb.	.43 — .44
Salammoniac, gray gran	lb.	.18 — .19
Salammoniac, white gran	lb.	.17½ — .18
Sal soda	100 lb.	1.35 — 1.40
Salt cake	ton	20.00 — 25.00
Silver cyanide, based on market price of silver	oz.	... — ...
Silver nitrate	oz.	.62½ — .63
Soda ash, 58 per cent., light, flat (bags)	100 lb.	2 25 — 2.30

Soda ash, 58 per cent., dense, flat	100 lb.	4 00	—	4 10
Sodium acetate	lb.	Nominal

INDUSTRIAL NEWS

Plant Construction—Catalogs—New Publications

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Machine & Foundry Co., East Birmingham, will rebuild part of its plant. Estimated cost, $100,000.

MOBILE—The Consumers Dye Wood Products Co., capitalized at $300,000, plans to build a large dye plant here. The foundations of the plant, which will be located at Choctawa Point, have already been put in. G. A. LaVelle, Marietta, O., president.

SHELBY. The Shelby Chemical Co. will build a plant for the manufacture of wood chemicals. Estimated cost, $600,000. M. W. Bush, President of the Shelby Iron Co., is interested

WYLAM (Ensley P. O.)—The Steel Cities Chemical Co., 5 Mine St., Birmingham, will rebuild its plant here recently destroyed by fire.

Arkansas

TEXARKANA—The Texarkana Cotton Oil & Fertilizer Co., 600 East Broad St., will remodel its cotton seed oil mill.

California

LOS ANGELES—The Western Chemical Products Co., manufacturer of potassium permanganate and strontium nitrate, will erect a plant at Vernon.

MARE ISLAND—The Bureau of Yards and Docks, Navy Dept., Washington, D. C., will build an addition to the machine shop at the north end of the Mare Island Navy Yard. Estimated cost, $350,000.

OAKLAND—The Hammer-Bray Foundry, foot of Twenty-sixth Ave., will build the second and third unit of its plant.

SAN FRANCISCO—The Pacific Foundry Co., Eighteenth and Harrison Sts., will build an 80 x 250 ft steel addition to its plant.

TEHACHAPI—The Gold State Mining Co. will install a thirty-ton mill here. Martin J. Errecarte, manager.

Colorado

BONANZA—The Rawley Mining Co. will build a three hundred ton mill here.

Connecticut

HARTFORD—The Colt Manufacturing Co., manufacturer of fire arms, Vandyke Ave., has awarded the contract for the construction of a one-story, 46 x 96 ft., reinforced concrete factory addition to Ellison Construction Co., 60 Prospect St. Estimated cost, $16,000.

HARTFORD—The Terry Steam Turbine Co., Windsor Ave., has awarded the contract for the construction of a one-story, 42 x 468 ft., brick mill construction factory addition to Ellison Construction Co., New Park Ave. Estimated cost, $45,000.

Illinois

CHICAGO—Fleischman Co., 427 Plum St., has awarded the contract for the construction of a four-story, 62 x 85 ft. steel and brick factory on Kingsbury and Weed Sts. for the manufacture of yeast, to H. W. Green Construction Co., 8 South Dearborn Sts. Estimated cost, $90,000.

CHICAGO—The Groen Manufacturing Co., copper-smiths, 2113 North Kenneth Ave., will build a one-story, 50 x 100 ft. brick factory. Estimated cost, $10,000. T. J. Reynertson, 1937 North Crawford Ave., architect.

CHICAGO—The Henry Lindahl Machine Co., Lake and Morgan Sts., has awarded the contract for the construction of a three-story, 50 x 100 ft., mill construction factory to R. L. Brockob, 2122 West Twenty-first St. Estimated cost, $60,000.

CHICAGO—Wilder & Co., 228 West Lake St., has awarded the contract for the construction of a five-story, 50 x 125 ft. reinforced concrete and brick factory for the manufacture of leather, to Mueller Construction Co., 179 West Washington St. Estimated cost, $75,000.

Indiana

ANGOLA—The Sevison Magneto Co. will build a factory here. Estimated cost, $29,000.

HAMMOND—The Standard Steel Car Co. has awarded the contract for the construction of a one-story, 150 x 400 ft. concrete, brick and steel factory for the manufacture of steel tires, to Austin Co., 16112 Euclid Ave., Cleveland, Ohio. Estimated cost, $100,000.

VINCENNES—The Marsh Co., Eleventh and Nicholas Sts., will build a one-story, 65 x 65 ft. addition to its factory to be used for the manufacture of drawn brass and steel tubing. Estimated cost, $32,000.

Kentucky

LOUISVILLE—J. B. Speed & Co., manufacturers of lime and cement, Speed Building, will build a potash plant seven miles from Louisville for the extraction of potash from the clay soil. Estimated cost, $100,000.

Kansas

WICHITA—The Universal incinerator Manufacturing Co. will build a two-story, 50 x 100 ft. reinforced concrete, brick and steel factory. Estimated cost, $25,000.

Maryland

BALTIMORE — The Bartlett-Hayward Co., Scott and McHenry Sts., will enlarge its munitions plant. Estimated cost, $18,000,000. The company purchased something over 21 acres of land on Columbia Ave. several months ago and at the same time took under lease from the City Park Board a much larger area adjoining this tract and Carroll Park.

BALTIMORE—The Rockefeller Foundation, New York City, will build a seven-story, reinforced concrete and brick laboratory on Monument St. to be used by John Hopkins Medical School for research work. Estimated cost, $700,000. Archer & Allen, Central Savings Bank Building, architects.

GLENWOOD—The Baltimore & Ohio R. R., Baltimore has awarded the contract for the construction of locomotive repair shops here, to Westinghouse, Church, Kerr & Co., 37 Wall St., New York City. Estimated cost, $1,700,000.

Massachusetts

BOSTON—Linde Air Products Co., 30 East Forty-second St., New York City, will build a one-story, 125 x 160 ft. reinforced concrete and brick factory for the manufacture of oxygen, on East First and K Sts. Estimated cost, $100,000. T. W. Goodrich, c/o owners, engineer.

CHELSEA—The Chelsea Foundry Co., 333 Third St., will build a one-story, 60 x 100 ft. foundry addition. Estimated cost, $15,000. S. S. Eisenberg, Exchange Building, architect.

HYDE PARK—The Mason Regulator Co., 1190 Adams St., Dorchester, has awarded the contract for the construction of a three-story, 80 x 160 ft. brick manufacturing building here, to John T. Scully Foundation Co., First St., East Cambridge. Estimated cost, $140,000.

ORANGE—The New Home Sewing Machine Co. has awarded the contract for the construction of a one-story, 103 x 353 ft., brick and steel plant for the manufacture of shells, to Casper Ranger Construction Co., Bond St., Holyoke. Estimated cost, $70,000.

ROXBURY—The Trustees of Harvard College, Harvard Medical School, Cambridge, will build a laboratory at 695 Huntington Ave. Estimated cost, $60,000. Coolidge & Shattuck, 122 Ames Building, Boston, architects.

Michigan

DETROIT—The Murchey Machine & Tool Co., Richmond Ave. and East Grand Boulevard, will build an addition to its plant.

MUSKEGON—The Campbell, Wyant & Cannon Foundry Co., Sanford St. and McKinney Ave., Muskegon Heights, has purchased ten adjoining lots and will build an addition to its plant.

PONTIAC—The Precision Castings Co. will rebuild its plant here which was partly destroyed by fire entailing a loss of $50,000.

Missouri

JOPLIN—The North American Mining Co., 715 Frisco Building, will build a concentrating plant at its mine, requiring sludge tables, compressors and crushers. Estimated cost, $60,000. W. R. Shanklin, 715 Frisco Building, mine engineer.

JOPLIN—Playter Bros. Mining & Reality Co., 315 Wall St., will build concentrating plant here. Estimated cost, $75,000. A. M Brannon, trustee.

JOPLIN—The Reindeer Lead & Zinc Co. will build a one hundred and fifty-ton concentration mill at its mine here. Estimated cost, $40,000.

KANSAS CITY—The Butler Manufacturing Co., manufacturer of steel products, 1324 Grand Ave., will build a one-story, 125 x 270 ft. plant on Eastern Ave., Sheffield.

ST. LOUIS—The Moon Motor Car Co., 4401 North Main St., has received a $2,000,000 order for large shells for the army and will build extensive additions to its plant here. The McDonald Engineering Co. ,an engineering subsidiary, will assist in the manufacturing.

ST. LOUIS—The St. Louis Lead & Oil Works, Manchester and Sublette Aves., has awarded the contract for the construction of a reinforced concrete and steel paint factory, to Chapline Construction Co., Post Dispatch Building. Estimated cost, $15,000.

Montana

BOZEMAN—The Montana State College of Agriculture and Mechanic Arts, has awarded the contract for the construction of a chemical laboratory, to Kroffganz & Frank, Butte.

Nebraska

OMAHA—The Overland Rubber & Tire Co. has purchased a site of land running from Thirteenth St. to Thirty-first Ave. and from Taylor St. north, to the Missouri Pacific Belt line on the south, and will build a plant here for the manufacture of tires and tubes of all kinds both for automobiles and trucks, and a general line of mechanical and surgical rubber goods. Estimated cost, $2,000,000.

PLATTSMOUTH—The Auto Power & Malleable Manufacturing Co., 729 First National Bank Building, Omaha, will build a one-story, 80 x 240 ft. foundry of fabricated steel and glass on a site surrounded by Main, Pearl, Second and Third Sts. Estimated cost, $150,000.

New Jersey

BLOOMSBURY—The Warren Manufacturing Co., manufacturer of paper, will build large additions to its plant. E. H. Wenzelberger, Reading Building, Easton, Pa., is architect

BOUND BROOK—The Calco Chemical Co., Bound Brook Road, will build additions to its plant. Estimated cost, $250,000.

ELIZABETH—Duesenberg Motor Corporation, Newark Ave., will build a brick testing plant. About $90,000.

HARRISON—The National Oil Products Co., Essex St., has acquired the plant here formerly owned and operated by the Elm Park Linoleum Works, Elm Park, Staten Island, and will equip same for its own use. The works comprise a twelve acre site with fourteen manufacturing buildings covering an area of about 250,000 sq.ft. floor space.

NEWARK—Martin Dennis Co., 859 Summer Ave., has awarded the contract for the construction of a one-story, brick factory for the manufacture of chemicals, to Salmon Bros., 526 Elm St., Arlington. Estimated cost, $30,424.

NEWARK—The Mass & Waldstein Co., 437 Riverside Ave., has awarded the contract for the construction of two one-story, 56 x 216 and 56 x 128 ft. brick buildings for the manufacture of chemicals, to H. M. Doremus Co., 36 Orange St. Estimated cost, $40,000.

NEWARK — The Mennen-Gerhardt Chemical Co., 40 Spring St., will alter its factory on Central Ave. Estimated cost, $42,500.

NEWARK—The Pierce-Butler & Pierce Manufacturing Co., 437 East One Hundred Sixty-second St., New York City, will build a one-story, 50 x 200 ft., concrete factory for the manufacture of steam and water boilers and plumbing fixtures on Colt St.

NEWARK—The United Oil & Chemical Co., Ave. R, will build a three-story addition to its plant.

PATERSON—The East Jersey Pipe Works, East Thirty-Sixth St., has purchased a site between 371 and 585 East Thirty-Second St., upon which a large addition will be erected.

New York

BIDGEFIELD PARK—The British American Chemical Co., 52 Vanderbilt Ave., New York City, has awarded the contract for the construction of factory buildings here, to Snare & Triest Co., 8 West 40th St., New York City.

BUFFALO—The National Aniline & Chemical Co., 351 Abbott Road, will build a three-story, brick and steel machine shop. Estimated cost, $85,000.

BUFFALO—The O'Neill Iron Works, 29 Perry St., will build a one-story brick and steel shop addition to its plant. Estimated cost, $45,000.

CORTLAND—The Cortland Specialty Co., 178 Railroad St., manufacturer of chemicals, will build an addition to its plant.

GLOVERSVILLE—G. Levor Co. has awarded the contract for the construction of a two-story, 75 x 115 ft. concrete and brick factory on Woodside Ave. for the manufacture of leather to A. E. Brace, 37 Hamilton St. Estimated cost, $35,000

LONG ISLAND CITY—The Meurer Steel Barrel Co., 575 Flushing Ave., will rebuild its one and two-story, 200 x 255 ft. brick factory on Third and Oliver Sts. Estimated cost, $75,000. L. Allmendinger, 20 Palmetto St., Brooklyn, architect

ROCHESTER—The High Speed Hammer Co., 307 St. Paul St., has awarded the contract for the construction of a 60 x 115 ft. machine shop on Norton St., to Curran & Swartout Co., Granite Building. Estimated cost, $25,000.

Ohio

CANTON—The Timken Roller Bearing Co., Deuber Ave., has awarded the contract for the construction of new factory buildings, to J. E. Moss Iron Works, Wheeling, West Virginia

CINCINNATI—The Cincinnati Gear Co., 1825 Reading Road, has awarded the contract for the construction of a one-story, 40 x 100 ft. concrete and brick addition to its factory to H. C. Hazen Co., 2070 Reading Road. Estimated cost, $30,000

CINCINNATI—The Proctor & Gamble Co., Gwynne Building, will build a three-and one-half story, brick and concrete factory between East Ave. and Millereek, Ivorydale. Estimated cost, $40,000.

CLEVELAND—The Cleveland Armature Co., 4732 St. Clair Ave., has awarded the contract for the construction of a two-story, 40 x 150 ft., reinforced concrete and brick factory, to the McMillin Co., 1794 East Fifty-Fifth St. Estimated cost, $20,000

CLEVELAND—The Cleveland Pneumatic Tool Co., 3734 East Seventy-Eighth St., has awarded the contract for the construction of a one-story, 51 x 182 ft. concrete and brick factory, to Allen Osborn Engineering Co., 700 Rose Building. Estimated cost, $35,000.

CLEVELAND—P. A. Geier, manufacturer of machinery, 5100 St. Clair Ave., will build a one-story, brick addition to its plant. Estimated cost, $12,000 Watson Engineering Co., Hippodrome Building, engineer.

CLEVELAND—The Independent Glue & Gelatine Co., 2106 Woodland St., will build a two-story, 84 x 186 ft. brick factory on Broadway near Twenty-Eighth St

CLEVELAND—The Reflex Ignition Co., 1788 Payne Ave., has purchased a site on West One Hundred and Sixth St. and will build a factory.

DAYTON—The Platt Iron Works, Keowee and Valley Sts., will build a one story metal factory. Estimated cost, $15,000.

MANSFIELD—The Rederick Lean Manufacturing Co., 366 Park Ave. East, will build a 100 x 420 ft machine shop and tool room addition to its factory

YOUNGSTOWN—The Raymond Concrete Pile Co., Andrews Ave., will build a 27 x 60 x 300 ft. brick factory for the manufacture of shells Estimated cost, $30,000.

Oklahoma

BARTLESVILLE—The Bureau of Mines has awarded the contract for the construction of a two story, 37 x 57 ft administration building and a 42 x 102 ft laboratory, to D. M. Wall, 2617 Agnes St Estimated cost, $30,000.

OKLAHOMA CITY—The Greater States Oil Corporation has purchased a forty acre site near Eastland upon which it will build an oil refinery Estimated cost $200,000

TULSA—The Lamphlack Manufacturing Co. will build a plant for the manufacture of lamphlack from natural gas

WALTERS—The United States Refinery Co. has purchased an eighty acre site here on which it will build an oil refinery Estimated cost, $60,000

Oregon

ASTORIA—The Astoria Paper Mills will build an addition to its plant Estimated cost, $250,000

Pennsylvania

BRISTOL—The Atlantic Refinery Co., 3144 Passyunk Ave., Philadelphia, has awarded the contract for the construction of a one-story addition to its plant here to Metzger & Fisher, Otis Building, Philadelphia.

PHILADELPHIA—The Barrett Co., Margaret and Bermuda Sts. has awarded the contract for the construction of a five story, 100 x 150 ft. reinforced concrete and brick factory for the manufacture of coal tar products, to A. R. Raff Construction Co., 1616 Thompson St. Estimated cost, $40,000

PHILADELPHIA—Berko Bros., Randolph and Wood Sts., manufacturer of structural steel, has awarded the contract for the construction of a one-story, 75 x 85 ft. brick ware factory, to M. Yellin, 7L North Franklin St. Estimated cost, $5,000

PHILADELPHIA—The Powers-Weightman-Rosengarten Co., 916 Parrish St., manufacturer of chemicals will build a one story, 55 x 70 ft addition to its plant at Ridge Ave. and Calumet St.

PITTSBURG—The Atlantic Refining Co., Fifty-Seventh and Butler Sts., will build a pressure still at its plant Estimated cost, $50,000.

READING—The International Money Machine Co., Kutztown Road, has awarded the contract for the consstion of a two story, 40 x 45 ft and a one story 60 x 142 ft concrete and steel factory buildings, to Austin & Co., Bulletin Building, Philadelphia. Estimated cost, $50,000.

Rhode Island

NEWPORT—The Bureau of Yards & Docks, Navy Department, Washington, D. C., received bids June 3rd for building a chemical laboratory at the U. S. Naval Torpedo Station, from T. A. Cassidy, 54 Ballston St., Fitchburg, Mass., $47,571, C. B. Maguire, Providence, $31,955, Darling Slade Construction Co., Newport, $36,000

Texas

COLEMAN—The Lone Star Oil & Refining Co., Manes Building, will erect an oil refinery to have a daily capacity of 500 barrels. Estimated cost, $50,000

HOUSTON—The Ka-Tex-O Oil & Refining Co. will build a large oil refinery here

Virginia

PORTSMOUTH—The Lime-Kola Co. will build a flavoring extract plant at 611 Edwards St.

Washington, D. C.

WASHINGTON—The Bureau of Yards & Docks, Navy Department, has awarded the contract for the construction of a mine laboratory, to Sumner Sollitt Co., Pullman Building, Chicago, Ill. Estimated cost, $75,000

Washington

SEATTLE—The American Foundry Co., 408 Occidental Ave., recently organized, will build an iron foundry with a daily capacity of fifteen to twenty tons.

SEATTLE—The Ark-O-Lith Products Co. will build a two story, 24 x 48 ft factory at 121 Wilton St. for the manufacture of building blocks, artificial marble and fireproof doors

SEATTLE—Gulowsen & Grei Co. Alaska Building, will build a one story 174 x 300 ft. hull construction. Grei engine manufacturing plant on Salmon Bay. Estimated cost $400,000. S. E. Sonnichsen, Downs Block architect

SEATTLE—The Heffernan Engine Works, 108 Railroad St. will build a two story, 50 x 174 ft. machine shop. Estimated cost, $25,000

SEATTLE—The Pacific Engineering & Construction Co. will build a one story, 70 x 120 ft addition to its machine shop and foundry

West Virginia

HUNTINGTON—The Chesapeake & Ohio Railroad Co., Richmond, Va., will build a one story machine shop here Estimated cost $500,000. F. J. Cabell, Richmond, chief engineer

WESTON—State Board of [illegible] having plans prepared for sewerage treatment plant for Weston State Hospital. The plant will consist of pumping [illegible] mentation tank, sprinkling filter, disinfecting plant and incinerating plant. Estimated cost $45,000. Charles [illegible] Drexel Building, Philadelphia, [illegible] neer

Wisconsin

MILWAUKEE—The National Brass & Metal Co. has let contract for [illegible] Foundry Co. for the erection of a [illegible] to its factory here. Estimated cost $[illegible]. H. J. Luer & Co., [illegible] engineers

MILWAUKEE—The [illegible] Wire & Iron Works, Reed St. and [illegible] Ave., has let contract to the Fuller-Lehr Co. for the erection of a one story, 75 x [illegible] ft. factory and office building. Estimated cost $[illegible]

WAUWATOSA—The Milwaukee Lighting Fixture Co., Thirteenth and Lloyd Sts., will build a one story, 75 ft. addition to its plant.

WYOMING PARK—The Heath Motor Car Co. has awarded the contract for the construction of a one story, 75 x [illegible] ft. factory and office building to J. W. Cook, Grand Haven, Mich.

Wyoming

WORLAND—The Pioneering Oil Products Co., Exchange Building, San Francisco, Cal. has purchased the Hyde Consolidated Refinery and will install an additional plant. Estimated cost $500,000

Ontario

BRANTFORD—The Motor Trucks Co., Ltd., Eagle St. has awarded the contract for the construction of a brick and steel shop and factory to P. H. Secord & Sons. Estimated cost $175,000

HAMILTON—The Dominion Steel Foundry Co., Depew St., will build a new plant. Estimated cost $[illegible],500,000

OWEN SOUND—The Great Lakes Steel Corporation, Ltd., 22 King St., East, Toronto, has purchased a factory here which it will remodel for the manufacture of steel products.

TILBURY—The Canadian Forgings & Socket Co. will build a foundry plant here. Estimated cost, $2,000

WINDSOR—The Menard Motor Truck Co., 100 London St., West will build a three story brick factory. Estimated cost $60,000. M. L. Menard, 10 Carson St. is manager

Canada

DESCHENES—The British American Nickel Corporation, Royal Bank Building, Toronto, has awarded the contract for the construction of a copper refining plant here to Bate, McMahon & Co., Ottawa. Estimated cost $1,000,000

LONGUE POINTE—The Montreal Locomotive Works, 145 St. James St., Montreal, will build an addition to its plant here

MONTREAL—The Canadian Aloe Chalmers Ltd., 162 St. Antoine St., will build a concrete, brick and steel addition to its Rockfield plant here. Estimated cost $25,000

Industrial Notes

THE DENVER FIRE CLAY COMPANY, Denver, Colo., founded in 1876, has recently been reorganized as a result of the purchase of the entire interest held by Wm. W. Case, Jr., by Mr. Leonard Buckwalter, wife of the founder of the business, and her three sons. Arthur H. senior member of the firm Buckwalter, Chanute & Company, Denver; Harold O. of New York and Capt. Robert B. an attorney of Denver, now in the American military service in France. This company specializes in clay products for smelting and other metallurgical work, produced from its own fire clay deposits near Golden, Colo. The company is also a large importer and exporter of all kinds of chemicals for laboratory and industrial purposes. The officers of the new company are as follows: President, Harold O. Bosworth who was formerly active in the company for 16 years, last as sales manager of the White Tar Company of New York. Vice-president, Claude Evans, recently manager of the assay department of the Mine & Smelter Supply Company, Denver. Secretary-Treasurer, Herman Landenberger who has been connected with the company for 20 years. George W. Lindsay will be factory superintendent

THE SEAMEN-KENT METALS COMPANY, Ltd., Montreal, one of the pioneers in the production of ferromanganese in America, has established a sales office in the Leader-Scott Building, Cleveland, O., with P. Pierce in charge.

THE NATIONAL ANILINE AND CHEMICAL Company transferred to exhibit quarters recently given at the Textile Show to the Work in U. S. A. exposition at the Grand Army Armory of Boston, which was particularly applicable to the purpose of the Latin-American Commercial League of the manner in which it demonstrates the growth and importance of the American dye industry

The [illegible] Company of America, Inc., has built and equipped a new factory, 721-733 East 133rd Street, New York City. The new building was occupied on April 25 and the company is now in position to make any article of fused silica demanded by the trade.

The Booth-Hall Company announce contracts recently received for the following units: A 1-ton furnace for the Queen City Foundry Company, Denver, Col., which is at present operating a converter steel foundry. A 2-ton furnace for the Monroe Steel Casting Company, Monroe, Mich., which is at present operating a single-phase electric furnace which will be replaced by the new unit. A 2-ton furnace for the New England Steel Casting Company, a new steel foundry which will be located at Springfield, Mass. A 2-ton furnace for the Four-Wheel Drive Auto Company, Clintonville, Wis., which is installing a new steel foundry to produce castings for trucks for the United States government. A 2-ton Booth-Hall furnace has recently been put into operation in the new steel foundry of the Avery Company, Peoria, Ill., for producing gears, pinions, and other agricultural machinery and tractor castings. A 1-ton unit is ready to be put into operation at the plant of the Duriron Castings Company, Dayton, Ohio. With the 5-ton unit which has been in operation at the Midland Electric Steel Company, Terre Haute, Ind., this makes three sizes of furnaces that the Booth-Hall Company has designed and put in operation.

The Everly N. Davis Chemical Corporation is a new company formed for the specific purpose of equipping and operating the new picric acid plant which is to be built by the War Department at Little Rock, Ark. Everly N. Davis, the president of the company, was formerly president of the Butterworth-Judson Corporation. The new company has just opened offices at 25 West 44th Street, where they are interested in hearing from reliable manufacturers of chemical equipment which they shall need in their plant.

The Driver-Harris Company of Harrison, N. J., announces the election of the following officers: Frank L. Driver, president; Arlington Bensel, 1st vice president; Leon O. Hart, 2nd vice president; Frank L. Driver, Jr., 3rd vice president; Percival E. Reeves, treasurer; Stanley M. Tracy, asst. treasurer; M. C. Harris, secretary. Mr. Wilbur B. Driver, formerly vice president, has retired from active participation in the business.

The Brown Hoisting Machinery Co. announces the appointment of Mr. H. D. Wright, manager of the San Francisco office, as Pacific Coast representative, to succeed the Colby Engineering Company in the Northwest territory.

The Brown Instrument Company, Philadelphia, has opened a new office at 2086 Railway Exchange Building, in charge of Mr. Paul H. Berggreen. The new office is established to meet the demands of business in the Southwestern part of the country.

The Marden, Orth & Hastings Corp., Cleveland, O., branch, moved into new offices in the Illuminating Building. The Cleveland office is in charge of Mr. Henry W. Galley, and takes care of all the trades using colors, chemicals and industrial and edible oils in the State of Ohio and in the Pittsburgh, Pa., and Louisville, Ky., districts.

Fuller-Lehigh Company is the style of the merger of the property and plants of the Lehigh Foundry Company and the Lehigh Car, Wheel & Axle Works of Fullerton, Pa. The properties of the two companies are adjoining and have been for a number of years under the same management. The change is one of name only. The executive personnel remains the same, and the same high standards of quality of products and efficiency of service established in the past will be maintained. The office and works are at Fullerton, Pa.

Mitsui and Co., Ltd., announce the removal of their office to 65 Broadway, New York City.

The Joseph Dixon Crucible Company announces the election of the following directors and officers at the last annual meeting: Directors: George T. Smith, William G. Bumstead, J. Schermerhorn, George E. Long, Edward L. Young, Harry Dailey, Robt. E. Jennings. Officers: George T. Smith, president; George E. Long, vice president; J. H. Schermerhorn, vice president; Harry Dailey, secretary; William Koester, treasurer; Albert Norris, asst. secretary and asst. treasurer.

The American Graphite Company, a subsidiary of the Joseph Dixon Crucible Co., has the same directorate as the Joseph Dixon Crucible Co. and the following officers: George T. Smith, president; George E. Long, vice president; J. H. Schermerhorn, treasurer; Harry Dailey, secretary.

Colorado Iron Works Company announces the removal of its Eastern office to 30 Church Street, New York City.

Sir Isaac Pitman & Sons, Ltd., announces the recent purchase of all the existing copyrights of the numerous scientific and technical books previously issued by Messrs. Whittaker & Company of London, and in future the American agency for these works will be controlled by Isaac Pitman & Sons, 2 West 45th Street, New York. This series includes many important works relating to aeroplanes, submarines, wireless telegraphy, etc.

The Wilputte Coke Oven Corporation has been awarded a contract for the construction of forty (40) Wilputte ovens, with extensions to the existing byproduct plant and benzol plant, by the Citizens Gas Company of Indianapolis. Work has been started and the plant is expected to be in operation by December, 1918.

The Wheeler Condenser & Engineering Co., Carteret, New Jersey; Bulletin 108-B on centrifugal pumps, illustrating the turbine-driven geared centrifugal pumps; bi-rotor, tri-rotor; electric driven; small belt-driven; small high-speed; side, end and bottom suction; vertical shaft; pumps for either series or parallel operation; and special slow-speed engine driven pumps. Test curves made by both manufacturer and customer are included.

Clarage Fan Company, Kalamazoo, Michigan, Catalog No. 7 on section drying cabinets giving details of dryer and prices.

The Cutler-Hammer Mfg. Co., Milwaukee, Wis.; a folder illustrating and describing the battery charging equipment for industrial electric trucks. Also a folder, No. 233, on C-H Industrial Stores.

The Walter A. Zelnicker Supply Company, St. Louis, Mo.; Bulletin No. 243, May 14, 1918, on power plant equipment and machinery for immediate shipment.

The Armstrong Cork & Insulation Company, Pittsburgh, Pa.; a booklet entitled "Satisfaction or ——" which deals with the subject of industrial drinking water systems. Copies will be supplied upon request.

The M H-Aterite Company, Inc., 55 John Street, New York; Bulletin No. 4, Jan. 1, 1918, on special information for superintendents of oil refineries in relation to valves, fittings, etc.

The Locomotive Pulverized Fuel Company, 30 Church Street, New York; Bulletin 4, March, 1918, on the use of powdered coal or lignite with "Lopulco" combination feeder and mixer.

The Allis-Chalmers Manufacturing Company; Bulletin 1454, January, 1918, on their dust collector.

The Buffalo Forge Co., Buffalo, N. Y.; Sections No. 100 and 108 describing portable and stationary forges.

J. H. Mathews & Sons, Wellsburg, West Va.; a booklet entitled "Builders of Glass Works."

Gem Stopper Company, Philadelphia, Pa., Bulletin No. 8, January, 1918, on universal acid carboy stoppers, asbestos gaskets and metal fasteners.

New Publications

Tycos Gravity and Temperature Tables for Mineral Oils from Determinations of the Bureau of Standards and Other Tables for General Testing and Refinery Practice. Compiled and edited by E. N. Hurlburt. Published by the Taylor Instrument Companies, Rochester, N. Y. Price, $1.00.

Report of a Conference held under the auspices of the Committee on Work in War Industries of the National War Work Council, Young Men's Christian Association. Among the speakers were Judge E. H. Gary, A. C. Bedford, John J. Eagan, and others.

The Rockefeller Foundation, A review of its war work, public health activities, and medical education projects in 1917. By George E. Vincent.

University of Texas Bulletin, No. 1752, Sept. 15, 1917. Boiler Waters; Their Chemical Composition, Use, and Treatment. By W. T. Read, Chemist, with a preface by E. P. Schoch, head of the Bureau of Economic Geology and Technology Division of Chemistry.

New Geological Survey Reports: Lime in 1916. By G. P. Loughlin; Mineral Waters in 1916. By Arthur J. Ellis, with a comparison of American and European mineral waters. By Alfred A. Chambers; Gold, Silver, Copper, Lead and Zinc in Idaho and Washington in 1916. By C. N. Gary; and Copper in 1916 (general report), By B. S. Butler.

New Bureau of Mines Publications: The Use of Permissible Explosives in the Coal Mines of Illinois. By James R. Fleming and John W. Koster, Bulletin 137; Concentration Experiments with the Siliceous Red Hematite of the Birmingham District, Alabama. By Joseph T. Singewald, Jr., Bulletin 110; Oil-Storage Tanks and Reservoirs, with a brief discussion of losses of oil in storage and methods of prevention. By C. P. Bowie, Bulletin 155; and Initial Priming Substances for High Explosives. By Guy B. Taylor and W. C. Cope, Technical Paper No. 162.

The Storage of Bituminous Coal. By H. H. Stock, University of Illinois. Bulletin Vol. 15, No. 27. A 200-page pamphlet issued in view of the recent coal shortage. It is the purpose of the circular to present a review of modern practice governing the storage of coal. The discussion is confined to bituminous coal which has given so much trouble owing to its tendency toward spontaneous combustion while stored. Another pamphlet bearing on the same subject is Technical Paper No. 172 of the U. S. Bureau of Mines, "Effects of Moisture on the Spontaneous Heating of Stored Coal" by S. H. Katz and H. C. Porter.

The Thermal Testing Plant. By R. B. Fehr. Bulletin No. 24 of the Engineering Experiment Station, of the Pennsylvania State College. A report on the work of the testing plant for the years 1916 and 1917, describing apparatus and method of testing, calibration of instruments, etc.

Manufacturers' Catalogs

The Galvanizing Corporation of America, Brooklyn, N. Y.; a booklet on Electro-Galvanizing the "Standard" Way, showing the advantages of lime as a protective agent.

Ludlum Steel Company, Watervliet, N. Y.; a catalog on the manufacture of steel and the use of various alloy elements. The language employed throughout the catalog is that of the shop man and not the metallurgist. This catalog and treatise on the allotropy of steel and the alloying of steel is for distribution, free of charge.

The Hydraulic Press Mfg. Co., Mount Gilead, Ohio; a new catalog on hydraulic valves and fittings, describing this company's complete line, including hydraulic presses, pumps, accumulators and intensifiers for every high-pressure purpose. Copies may be had by addressing the above company.

The Harshaw Fuller & Goodwin Company, Cleveland, Ohio, a book on "Enamels" by Robert D. Landrum. This book is a collection of various articles published by the author in the different technical journals.

Link-Belt Company, Chicago, Ill.; Book No. 312 on the silent chain, the efficient drive for machine tools.

The Titanium Bronze Company, Inc., Niagara Falls, N. Y.; a booklet on high-conductivity copper castings.

The United Filters Corporation, Brooklyn, N. Y., has issued three bulletins, Nos. 100 to 102 inclusive, covering Kelly and Sweetland pressure leaf-type filters, also the American continuous vacuum filter.

W. S. Rockwell Company, 50 Church Street, New York: Bulletin No. 34 on forging and heating furnaces describing the Economzer shield type, issued May, 1918; Bulletin No. 35 on annealing furnaces, rolling mill type.

Monarch Engineering & Manufacturing Company, Baltimore, Maryland: A bulletin describing the new Monarch vertical non-crucible tilting metal melting furnace.

The Pfaudler Co., Rochester, N. Y.: Bulletin C5 on glass enameled steel equipment for the chemical industries.

Colorado Iron Works Company, Denver, Colorado: Catalog No. 28-C on the continuous filtration with the Portland filter, distributed in the East by the Colorado Iron Works Company, 30 Church St., New York City.

Hoskins Manufacturing Co., Detroit, Mich.: Catalog No. 3, April, 1918, on Hoskins pyrometers and chromel couples.

James G. Biddle, 1211-13 Arch Street, Philadelphia: A bulletin on Biddle's engineering specialties for testing.

The Harris Calorific Co., Cleveland, Ohio: A bulletin on high temperature gas apparatus and also welding and cutting of metals.

Wheeler Condenser & Engineering Company, Carteret, N. J.: A catalog on the Lillie evaporator for waste waters, including tank waters, runaway waters, distillery slops, steffins waters, etc.
